Before passing on to the main objects of this address, it is incumbent on me to refer to one or two alterations in our teaching staff which have taken place during the past year. By the appointment of Professor Rutherford to the chair of the Institutes of Medicine at the University of Edinburgh, this College sustained a loss which was severely felt, not only by his late colleagues, but by every student who had the great advantage of attending his carefully prepared and graphic demonstrations and lectures. The energy which he infused into his teaching was so evident as to be at once reciprocated by everyone who was brought into contact with him, and greatly increased the difficulty of finding a worthy occupant of the vacant chair. I can, however, congratulate the authorities of this College and our junior students on the happy selection that has been made in the appointment of his successor. Dr. Gerald Yeo has supplemented a brilliant career as a student at Trinity College, Dublin, by some years of special physiological training in the best continental laboratories, and has already secured an excellent reputation both by his original researches and by his success as a teacher in the Carmichael School of Medicine at Dublin. We therefore confidently anticipate that new laurels will be added to the ancient glories of our physiological chair—a chair that has been successively occupied by such distinguished teachers and physiologists as Todd, Bowman, Beale, and Rutherford. I offer our new professor every cordial greeting.

Not only can I congratulate King's College on securing the services of Dr. Gerald Yeo, but I can also congratulate him on being able to begin work at once in a new laboratory, which I believe will, in the completeness of its arrangements and the perfection of its appliances for teaching, vie with any in Great Britain, and with most of those on the continent.

Another link in the chain which binds us to the past history and traditions of King's College has been severed by the resignation of Professor Cartwright, whose genial disposition and courteous manner were so fully appreciated by successive generations of students during the long period of thirty-one years. The appointment of Mr. Hamilton Cartwright to the senior offices will give him a wider field for the energy and talent which he displayed whilst holding the junior post.

The last two or three years have been very eventful in the history of the medical school of this College, and the large infusion of new blood into its teaching staff must make all of us anxious for its future. The recent date of my own appointment and my great attachment to our *alma mater* will be an excuse for my pointing out that the patriotism necessarily implied in so many of your recent vacancies being filled by King's men must be an additional claim on all old King's students, and instil into us a worthy emulation in striving to maintain our ancient prestige.

The first question which confronted me in thinking over the subject-matter for this occasion was the obvious one,—What is the purpose of an introductory lecture? When they were originated they were felt to be necessary in order to explain to the new-comer the objects with which the various subjects in our medical curriculum were introduced, the best mode of obtaining a fair knowledge thereof, and to point out to him what parts of the collateral sciences had a practical bearing on the exercise of our professional avocations. But gradually most lecturers have strayed from this path: many have made use of such addresses to declaim on the peculiar beauty and excellence of that branch of science to which they had devoted their attention; some took occasion to show the great claims of our profession on the public, and urged the advances made therein in a few previous years, or contrasted our medicine with that of bygone ages; whilst others have even been tempted to take prophetic glimpses into the dim vistas of its future. Thus critics have been led to expect, on these occasions, some explanation of our *raison d'être*, or some new guarantees of our onward progress, and their omission from many of the addresses of last year was thus commented on by a leader-writer in *The Times*:—"The lecturers who would instruct the educated portions of the public with regard to the actual position of medicine and surgery among the sciences, with regard to their weaknesses and shortcomings, as well as with regard to their achievements and strength, would render a highly important service." He quite forgets the primary object with which the lectures should have been delivered. I prefer reverting in some measure to the old ideas, and shall address you on the objects of your medical education, and the spirit and methods with which the various subjects embraced therein should be studied, rather than discuss any of the various medical questions in which the lay public are so greatly interested. These are topics for more suitable places, and to be dealt with by the leaders of our profession.

I shall not detain you with a detailed list of the numerous medical studies, for what they are, and in what order they should be attended to, are so explicitly laid down by the various examining bodies, that, however much and in whatever way we may be inclined to differ therefrom, we are powerless to alter them. I take it that most of you are already familiar with their general purposes, and the order in which they must be mastered. To those who are ignorant thereof, the Dean or any of your teachers will give every explanation.

I must first deal very shortly with a few points in the preliminary or general education of the medical student. I regret very much that the standard of the subjects required by some of our examining bodies is still very low, and that the course of education in some even of our higher-class schools is still very deficient, for it throws additional work on the student at the earliest and most difficult part of his career, and prevents the teacher from at once entering on the details of his subject. Thus the demonstrator of anatomy finds himself obliged not only to teach his science, but to point out the elementary laws and facts relative to the life-history and functions of living beings in general, and very frequently to supplement this by the explanation, and occasionally by the orthography, of almost every technical term that he is compelled to use, whether derived from the ancient or the modern languages. This, as has been well put by a colleague of mine (Prof. Baxter), is "as if a professor of Arabic were to begin his course by teaching his class how to spell their mother tongue." It might easily be obviated by requiring such a knowledge of the Greek and Latin classics as would explain our medical terminology; of physics, as would ensure that the student was familiar with the fundamental laws that govern the world of inorganic nature; and of biology, that he should understand the elementary data of that science. By this I do not mean the acquirement of every detail as is insisted on in some of our examinations—the Preliminary Scientific M.B. of the University of London, for example; but on such a course as would call forth and exercise the observation and reasoning powers of the future student. Those of you who start, having had these faculties at all cultivated in the ordinary routine of school life, have obtained an immeasurable advantage at the outset of your medical career. I am glad to see that this plan of study is rapidly supplanting the old one, of knowing some of the practical details of the arts of medicine and surgery through an apprenticeship ofttimes extending over the most important part of one's student life. As one brought up under the old system, and who, before attending a lecture or seeing the interior of a hospital, was fairly conversant with the mystery of bandaging, and could perhaps set an everyday fracture, or, without knowing the why or the wherefore, deftly combine the pharmacopœial armamentarium against each and every case of vomiting or attack of dyspnœa, allow me to assure any of you who deplore your ignorance of such matters that they will come unknown and unforeseen in the after-part of your clinical studies, and when you are far better able to assess them at their proper value. The path of success lies in an early guidance into the proper methods of study, and everything technical comes easily afterwards in due rotation. In insisting on this, I am aware that I am at variance with many excellent authorities and teachers; but I know of no instance in which a student who has devoted his time in early years to a scientific course of study has not mastered all the details of our practical experience with as great facility as he would have done had he occupied the first year or two of his professional education in their acquisition. I therefore congratulate those of you who are commencing your purely medical education with a foundation of scientific knowledge—its aims and its methods. I consider that system by which an acquaintance with the collateral sciences is obtained before the student begins his more strictly medical education one of the most important and useful innovations of late years. In fact, it seems to me that as a knowledge of physics, mechanics, and inorganic chemistry is essential in the early training of an engineer, so an acquaintance with elementary biological phenomena and with their laws is a preliminary necessity for every student of medicine. The more general sciences, then, such as zoology, botany, physics, and inorganic chemistry, should precede the special ones of human anatomy, physiology, and organic chemistry, on which the principles and practice of medicine are based, in order that the medical student may make the best use of the limited time at his command, or otherwise he will either entirely fail to obtain the necessary habits of thought induced by scientific studies, or will only gain them with a vast expenditure of time and trouble. Although, in the case of most of you, this acquaintance with scientific study has not yet commenced, I must as forcibly as possible impress on all its necessity in the formation of the typical physician and surgeon. I earnestly hope that no mere question of the after-utility of so much of this or of that special science will tempt you to limit yourselves to a purely technical education, and so prevent your obtaining the benefits of a liberal scientific culture.

Medicine is advancing daily, and in such advance "the ultimate court of appeal is observation and experiment, and not authority"; and the sooner you educate yourselves to observe closely and carefully, and to draw correct inferences from your observations, the more self-reliant you will become, the less liable to be turned hither and thither by every new-fangled idea in medical doctrines, and the less servile a follower of some dominant theory or captivating teacher." "L'homme," says Pascal," "est visiblement fait pour penser; c'est toute sa dignité et tout son mérite, et tout son devoir est de penser comme il faut."

Another great advantage of early scientific training is that, at the most impressionable period of life, it brings you face to face with facts and not with mere words only, and teaches you to appreciate the great lesson that "learning and knowledge in science, as in life, are distinct; whereas, in the world of letters, learning and knowledge are one." In medicine you will quickly find that your books and your teachers are guides only; you cannot depend on them exclusively: new problems in disease caused by a never-ceasing change in the circumstances acting on the organism, and by alterations in the organism itself, partly due to those circumstances, and partly, perhaps, to its normal evolution, will speedily necessitate your judging for yourselves. The best teaching that you can have is that which leads you to educate your reasoning powers, instead of stultifying them by artificial tricks of memory or other similar devices which have in the mind a verbal existence only, instead of establishing therein some definite image. This fixation of something almost tangible in distinctness is nearly the only means of acquiring *real* knowledge, and its superiority is exemplified by the well-known advantage of pictorial illustration in teaching the young; and, again, when we consider that, however abstract any word may have become, it originally had a purely concrete meaning, and that the proverbs of all nations—so pithy, of such vast signification, and so easily recalled—consist usually of a natural fact, selected as a picture or parable of a moral truth. "A rolling stone gathers no moss"; "long-lived trees make roots first."

It is your privilege that of late years the lecture system, which formerly was almost exclusively in vogue, is supplemented in every branch of medical science by systematic demonstrations, whilst but a short time ago these were made use of in the teaching of anatomy only. This, however, is no new plan of instruction, but herein we find history reproducing itself. In the earlier days of each science, when learners were few, whatever might have been the paucity of material, the teacher exercised a direct and personal influence over his pupils by demonstrating to them clearly and explicitly the facts on which the ideas that he sought to inculcate were based. But when in the sciences dealing with human life and its conditions prejudices overmastered the teacher, and pupils became more numerous, the lecture system, which was sufficient to spread a knowledge of the abstract and more exact sciences, gradually took the place of, instead of merely guiding, the practical study of the concrete sciences, and we have only recently returned to that method which so clearly attested "the wisdom of the ancients." The well-known pictures of "The Anatomical Lesson," by Rembrandt, and of "Harvey demonstrating his theory of the Circulation of the Blood to Charles I.," by Hannah, show how earnestly the pioneers of our science endeavoured to excite the enthusiasm of their contemporaries by this mode of instruction. And here I would venture to hope that no extraneous difficulties will be thrown in the way of carrying out, under proper and humane regulations, this method of teaching that all-important science, physiology. "Use your eyes as well as your ears" was one of the first axioms instilled into me by our distinguished senior surgeon, and those who interfere with this mode of imparting knowledge will have much to answer for. That penal regulations should be demanded to restrict the advancement of any branch of scientific inquiry is surely to forget the lessons of history, and to ask us to return to the darkness and ignorance of the first fourteen centuries of our era, and which were only overcome when the "giants of those days," Descartes, Galileo, and our own Bacon and Newton, made the first onward step from the time of the early Greek and Roman philosophers, by applying physical methods to the investigation of natural phenomena, and by substituting the inductive mode of reasoning for that purely deductive plan which had alone been used in substantiating the truths of the mathematical sciences. Progress in medicine is, to borrow a phrase from Mill, "a function of two variables"—direct observation and novel experimentation, and is perfected by correct inductive reasoning, which alone can give facility in separating the real points of importance in a given case from those that are adventitious or subsidiary. Indeed, the cultivation of the same faculties and an appreciation of the same methods are requisite even to follow the scientific history of our profession, or to estimate fairly and justly its present position; and, unless we are able to judge of every advancing step from this standpoint, we are merely taking a "leap in the dark" at the bidding of someone perhaps as blind as ourselves.

I shall now pass on to show that the earliest studies to which you will have to pay your attention are eminently qualified to strengthen these faculties, and to render you skilful in their employment. It is hardly necessary for me to remark that it is impossible to practise our profession without doing a vast deal more harm than good, unless we possess a thorough mastery of the technical parts of anatomy. I may, however, insist on the importance of *medical* anatomy technically, as well as those portions which are more necessary for the attainment of *surgical* skill and precision, and which are in general more prominently brought before your notice. Painstaking and accurate dissections can alone give that aptitude in the use of the knife and of the hands which is expected of the surgeon. If these were all the benefits—great though they are—that any of you should derive from the study of anatomy, I should still consider that you would lose the greater portion of its advantages, for it ought to teach you to observe and see things for yourselves, to study relations in size, position, and importance, and to cultivate your powers of memory. To those who have had in their scientific studies a *practical* training in comparative anatomy or in structural botany, this subject will be merely a further step along the same road, and there will be but little difference in the plan by which it is to be mastered; whilst to those who start without such an advantage it will be the first means—as, indeed, it is one of the best—of calling forth your powers of observation.

Physiology and chemistry are of vast importance as educational factors. The latter shows how constant and definite is the relation between cause and effect, and how the slightest modification in the circumstances under which an experiment is performed leads of a necessity to a modification in the conclusions that would be drawn from that experiment. Both of them necessitate the closest observation; they also lead the mind from minute details through a systematic classification up to the widest generalisation, and being eminently progressive, stimulate the inventive faculty, and at the same time discipline and develop the reason. When contrasted, they teach us how simple, definite, and exact are the laws that govern the inorganic world in comparison with the complexity and difficulty of the problems which open before us when we once enter the domain occupied by living organisms. Physiology in its present condition is far removed from the position of an exact science like mathematics, and is therefore of especial significance in making us cautious in our conclusions, in leading us to estimate accurately the value of approximate and probable data, and in teaching us how causes—slight in appearance—persist, grow, and develop, so that the result never becomes final, but quickly surpasses any conception which might be formed from an acquaintance with the laws of dead matter. This is, in fact, one of our most instructive lessons, and one which we are daily called on to correctly estimate and value, even in the routine discharge of our professional duties. It is impossible to overrate the necessity of a technical knowledge of physiology and chemistry to the medical man, and indeed this is rarely lost sight of. Everyone eagerly inquires how much and what parts will it pay me to know, and few are so blind to their own interests as to be ignorant of such portions as they consider necessary from this point of view. The intrinsic and peculiar advantages derived from acquiring proper habits of thought by a careful and honest study of the laws and methods of these sciences are much less frequently taken into consideration. It is impossible to commence our journey in the right path too early. "Character is destiny," says Novalis, or as the idea has been expressed in a recent novel:—"You don't know that you are forming a habit; you take each act to be an individual act which you may perform or not at will; but all the same the succession of them is getting you into its power. Custom gets a grip of your ways of thinking as well as your ways of living; the habit is formed, and it does not cease its hold until it conducts you to the grave."

In pleading thus earnestly for your early acquisition of the laws and methods of scientific inquiry, I would add one other consideration. Few can pursue such studies without taking an especial interest in, and gaining a great delight for, some branch of science; and this becomes an important source of relaxation and pleasure in the moments that can be and are snatched from even the busiest professional life. They give the brain that change of pursuit and occupation which is requisite to relieve the monotony that enters into our profession, as well as into other avocations. With what keen relish does the educated mind, when overburdened with the cares and anxieties of everyday practical life, turn to the contemplation and investigation of some congenial nook in the wide field of nature, and how intense is the satisfaction of making even one step toward that "untravelled world whose margin fades for ever." Is it not a peculiar boast, and one of the greatest glories of our profession, that so many of its most active members have found time to add to the world's ever accumulating treasures of knowledge, and that so many of the most prominent philosophers and votaries of science in every age have been enrolled in our ranks?

A consideration of the sciences which are concerned with human structure and functions in health leads us to those which are devoted to their study when the body has become the arena of those "ills that flesh is heir to." Morbid anatomy and pathology are the necessary complements of healthy anatomy and physiology; they are to be learnt by the same methods, and the cultivation of the habits of thought requisite for a proper knowledge of the latter will be sufficient to grasp the more advanced subjects. Bonetus in 1700 started morbid anatomy, S'Gräuwen in 1771 pointed out its utility and necessity, and Morgagni instituted a thorough inquiry into its domain, and published his results in 1793, in his "De causis et sedibus Morborum." Since then, this science has been, and is being, assiduously cultivated. I need scarcely impress on you that, however diligently you may attend the dissecting-room in your earlier student-days, you cannot conscientiously consider that you are making the best use of your opportunities unless you carry the same assiduity, earnestness, and close observation into the post-mortem theatre. Morbid anatomy is in general fairly well taught in our schools, but it would be a manifest advantage, and lead to immense results, if every physician and surgeon were to make it a point to carry his teaching in fatal cases from the bedside to the deadhouse, and to point out how far the symptoms observed during life are related to, and dependent on, the appearances disclosed after the death of the patient. Until this be done, the scrupulous care which is taken in the early education of the student will lose much of its benefit; guess-work takes the place of exact information, and his instruction becomes incomplete and unsatisfactory.

Anatomy, whether in health or disease, is a science of observation only, and as the mind will never remain satisfied with merely seeing and recording phenomena, but at once seeks with ardent quest the laws and conditions under which they occur, so we find pathology—the science of diseased functions—arising out of and aiding the inquirer into the facts of morbid anatomy, just as, since the time of Haller, physiology has sprung from and been the handmaid of normal anatomy. Here we are again landed into the region of experimental research and consequent inference, and it is only of late that we have passed the threshold and begun to formulate the laws of this science. Disease has already been displaced from its old position as an entity, entering into and leaving the body almost at will, and we now know that general or local perversions of nutrition, qualitative and quantitative, are sufficient to explain most of its phenomena. The prosecution of this department of knowledge is beset with even more difficulty than that of physiology, but in the last few years such great progress has been made that it is no longer unreasonable to hope that, although it must always wait on advancing physiology, it will soon do so as a very close attendant and companion. I regret that in none of our schools have systematic and independent arrangements for teaching this science been made, but as not long ago in all of them, and even now in some, a single teacher taught both anatomy and physiology, we may confidently anticipate in no very remote future a division of labour among those whose duty it is now to teach not only the facts of diseased structure, but also the causes, consequences, laws, and conditions of those alterations. Until this takes place, medical education will still leave a great desideratum.

And now, gentlemen, I must take leave of the scientific division of our studies—those bases on which the principles of medicine and surgery are founded, and shall refer to the *art* or practice of our profession. We must always remember that curing a patient of any disease or warding it off is a practical art, and not necessarily dependent on any theoretical science. As an engineer builds a bridge by the *art* of engineering, so do we cure an attack of gout by the *art* of therapeutics. As the stability of his work will depend on its being in accordance with the laws of mechanical and physical science, so must we be familiar with the sciences on which our practice is based; but as those laws will not enable him to span a river, or construct a railway, *per se* and without the necessary details of practical experience, so neither can we become proficient practitioners unless we possess an everyday acquaintance with the differences displayed by individuals, even when suffering from the same disease, and with the reactions of our various medicinal agents on different persons, or on the same person at different times and under varying conditions. Such uncertainties must always leave great scope for individual skill and dexterity. Most praiseworthy and excellent attempts are now being made to reduce the effects and actions of our drugs to a scientific system, and one shudders to think what vast harm may be done if this be checked by any legislative interference. It is my duty, however, to warn you that even the most sanguine of us must refer to a far distant date the time when this science of pharmacology, as it is called, and the science of pathology, will rest on such full and necessary data, that we shall be able to grasp, not only all the factors concerned in the production of a diseased state, but have within our power certain and reliable means of combating that condition. Every step in this direction is an unalloyed gain, but the complete fulfilment of such ideas seems to me quite Utopian, though who would pretend to limit the knowable? We must trust the perfection of creation so far as to believe that whatever curiosity the order of things has awakened in our minds the order of things can satisfy. "Tout est permis au philosophe," says Maupertuis, "pourvu qu'il traite tout avec l'esprit philosophique."

As our goal is not to be anatomists, chemists, physiologists, or pathologists only, but to be practical physicians and surgeons, we must be careful to supplement and to diligently carry on our education by the observation of disease and the effect of remedies thereon at the bedside, for here alone can we make ourselves proficient in the great essential of testing our principles by the results of practice.

Here, too, we shall discover the full benefits of that habit of close observation, that capacity for understanding the results of experimental inquiry, and that exercise of judgment, which I have so strongly insisted on as the fruits of perseverance in following and grasping the methods of our antecedent scientific studies. Every case of disease necessitates careful observation, and every dose of medicine which is given constitutes a great and momentous experiment.

The physiological and pathological inquiries by which we have been taught the complexities and contingencies that surround the study of living organisms, particularly of their origin, growth, development, and final degeneration, are now of special value. The exactitude and definiteness of the mathematical and physical sciences cannot be obtained by clinical experiments, and the necessity of an acquaintance with biological laws and methods is at once apparent. Even now I fear that the physico-chemical tendencies of most modern physiologists, by drawing particular attention to those phenomena of the living body which are capable of elucidation by physical means, are leading us to expect definite instead of approximate results, and so may endanger the advantages that a judicious medical training would necessarily derive from the investigation of the subtler problems of life. In all medical and vegetable forms the physiologist is reluctantly obliged to acknowledge that no chemistry, no mechanics, can as yet account for these phenomena.

Clinical medicine and surgery have their scientific and their practical sides, and both must be assiduously cultivated. Do not for one moment believe that the one is antagonistic to and subversive of the other; they are mutually complementary, and the only disadvantage is that we are sometimes tempted to strive after an exclusive proficiency in the one, and so by our own neglect entail a failure when we have to deal with the other. The Hindoos write in their sacred books, "Children only, and not the learned, speak of the speculative and the practical faculties as two." Just as the child begins the use of his fingers at the earliest age by moving them idly through mid-air or in endeavouring to grasp the first object within his reach, so you cannot begin the simpler manipulations of every-day practice too soon, and a regular attendance in the out-patient rooms will give you the necessary familiarity with the rudiments of our art, so that when you pass on to the clinical appointments and to your after-duties in the profession, it may not be remarked of you, as I once heard a late surgeon say of one of his dressers: "He has learnt everything; he can do nothing." He alone is learned who reduces his learning to practice, and practical skill without learning degrades our profession to the level of the days of barber-surgery and mediæval medicine. "If knowledge," said Ali the Caliph, "calleth unto practice, well; if not, it goeth away."

The history of our profession has been so often introduced into these addresses that I must ask your forbearance whilst I treat of it in its connexion with this subject. I shall endeavour to show that as medicine is two-sided, so its position has always been due to two factors, one dependent on the condition of science in general and the tendencies of speculative thought at a given period, the other due to tradition merely. On the former element depend its theories and that part of its practice which rests on a scientific basis; from the latter is derived the empirical portion of our art and knowledge. Sufficient attention has scarcely been given to the consideration that the theories and practice of the chief physicians in different ages were a reflex of the prevailing scientific ideas of those ages, and were mainly determined by the habits of thought engendered by the methods of investigation made use of in the cultivation of such sciences as were then most in vogue. A few typical examples will suffice to prove this.

In the first place, when we carefully examine the writings of the illustrious "father of medicine," we find them teeming with careful observations and faithful records—the necessary result of a consistent application to medicine of the scientific method of his immediate predecessors and contemporaries who devoted themselves to geometry, astronomy, and the simpler physics,—sciences of observation and simple relation. Medicine was pursued for a short time on the lines thus laid down; but, soon after the time of Galen, it became involved in the universal obscurity and ignorance, which swamped, not only science, but letters also. The historian of the middle ages thus describes the state of learning at that epoch:—"Law neglected; philosophy perverted till it became contemptible; history nearly silent; poetry rarely and feebly attempted; art more and more vitiated." As a consequence, we find ecclesiasticism occupying the place of medicine, and superstitions of the grossest kind flourishing. The curative agents of older times were displaced by the invariable mediæval resort to prayers, relics of martyrs, and holy water; thus paving the way for that greatest and most monstrous imposture, "the royal touch," which was extensively practised in France, England, and probably Scandinavia for several centuries, and which remains for all time an historical proof of the extreme credulity of even the best informed of the laity in matters affecting their bodily welfare. The materia medica of the Abbess Hildegarde, in the 12th century, contained the herring for curing the itch, the ashes of flies for affections of the skin, &c. As if to illustrate "The Perennials of History," and to demonstrate the persistence and perversity of that mental condition which believes, but does not judge, we find, even in the last century, one eminent divine extolling tar-water as a panacea, and another writing a long book of absurd recipes, in utter ignorance of the claims, position, and methods of medicine as a science. The last-mentioned authority recommends water in which a white onion, steeped in oil, had been boiled, as a means for procuring an easy delivery; three months' living on apples and apple-water, for curing cancer; the application of July wall-flowers, mixed with salt, to the sutures of the head, for the relief of a quartan ague; and water in which quicksilver had been digested for twenty-four hours as an infallible remedy for vomiting. He also gravely relates that a month's cold-bathing and water-drinking cured a Mrs. Bates, of Leicestershire, of a cancer in her breast, a consumption, a sciatica, and rheumatism which she had had for nearly twenty years.[*] We need not wonder that he attributed his own recovery from a chest affection to "sulphur and supplication," and lost sight of the curative effect of his physician's prescription which he carried out for four months. "If anything does thee good, it must be the country air, with rest, asses' milk, and riding daily."[†]

The revival of anatomy by Mundinus in 1315 did not at once benefit medicine, for it was then and for the next two centuries largely under the dominion of the twin visionaries, alchemy and astrology.

The desire for longevity and everlasting youth led to the administration of the nobler metals, but without any regard to the disease, the patient, or the power of the remedy. One of these elixirs is of considerable interest as having been recommended by Roger Bacon to Pope Clement the Tenth "to prevent the corruption of any constitution and the infirmities of age for many years." It is a good example of the jargon of these so-called sciences. "For the preparation of this elixir," says the inventor, Petro de Maharncourt, a Picard, "you must take that which is temperate in the fourth degree, that which swims in the sea, that which vegetates in the air, that which is cast out by the sea, that which is found in the bowels of a long-lived animal, a plant of India, and two creeping things which are the food of Tyrians and Egyptians, and let them all be properly prepared." These were interpreted by Roger Bacon to be "gold, pearl, rosemary, spermaceti, the bone found in a stag's heart, lignum aloës, and serpents." But, unfortunately for the reputation of the compound, Clement the Tenth died soon after. In the latter part of the fifteenth and throughout the sixteenth century, the great revival of letters and of science was taking place; individualism asserted itself against authority; intellectual energy displaced stupor; and so we find in the practice of medicine startling innovators, like Paracelsus, Basil Valentine, and Van Helmont, side by side with careful observers, as Fernel, Fracastor, and Linacre.

In 1415 Leonardo Da Vinci proclaimed the fundamental principle that experiment and observation are the only reliable foundations of reasoning in science; that experiment is the only trustworthy interpreter of nature, and is essential to the ascertainment of laws. Galileo and Descartes speedily applied this principle to the investigation of physical phenomena, and Harvey by following the same plan discovered the circulation of the blood. At this time the atmosphere was heavy with ideas derived from physical science, and its conceptions were for the first time introduced into medicine. The chemical physicians were gradually separating themselves from the alchemists, and contesting for superiority against the mathematical sect, and between them the old Galenists—the pure observers—were almost extinguished. In the middle of the seventeenth century, whilst Locke introduced the Baconian method of induction into metaphysics, his friend Sydenham raised English medicine from the lowest empiricism to a science of observation, and again brought into fashion "bedside study," accommodating his theories to his facts, instead of his facts to his theories. The next most noticeable feature in intellectual progress was the tendency to generalise, and to Newton physical science is indebted for the establishment of the great conception of causation which now supplanted those of mere sequence and concurrence. Here, again, we find a similar idea extending itself throughout the medical world. The vital principle or "anima" of Stahl, a necessary and unintelligent agent superintending and directing every part of the economy from its first foundation, assumed great prominence until it was assailed by Hoffmann, who referred such operations to nervous influence. Passing over the eclecticism of Boerhaave and Van Swieten, we find generalisation and induction pursued in the most philosophical spirit by Cullen, and giving rise to a rational empiricism, evidently reflected from the physiological teachings and methods of Haller.

The experimental investigations with which this century started were calculated to rouse even the most apathetic, and the philosophers of the next few years (1820–50) set themselves to arrange, classify, and methodise the results of previous inquirers, rather than to strike out into new directions. "Uniformity of the course of nature," and "conservation of force," became the scientific watchwords. Medicine passed through two new phases, the "statistical" and the "expectant." The latter was, in part, due to the influence of the doctrines of Hahnemann on medical practice, and in part to the necessary but involuntary assimilation of the methods of "natural history," now for the first time coming to the front in the rank of sciences, and insisting especially on accurate description and consequent specialisation.

---

[*] Primitive Physick, 1747, p. 28 et seq.

[†] The Journal of the Rev. J. Wesley, vol. ii., p. 262-264.

In our own time the greatest philosophic generalisation is undoubtedly due to Lamarck, Darwin, and Spencer, and the immense effects ascribed by us to hereditariness, the law of the transference of neuroses, and some of the modern views of adventitious growths—tubercle and cancer—are all clearly marked by a contact with the "hypothesis of evolution." But even this law is only a particular fact of some wider generalisation presently to disclose itself, and every new step we take in thought only reconciles various seemingly discordant facts, as expressions of a more general law. "Men walk as prophecies of the next age." Thus we see our science following in the same track as science in general, and gradually spreading in ever-widening circles—observation of facts, experimental research, inductive reasoning, simple generalisations, classification, description, and specialisation, and then an endeavour at wider and all-embracing generalisations. Science is a "self-evolving circle, which, from a ring imperceptibly small, rushes on all sides outwards to new and larger circles, and that without end. Our life is an apprenticeship to the truth that around every circle another can be drawn, that there is no end in nature (or in science), but every end is a beginning."

The study of medical science in this juxtaposition with the other sciences will explain most of the vagaries which have marked its progress.

To insist on the traditional side of our professional history will not occupy long. We must not forget that some of its traditions are now engrafted into scientific medicine, and stand on a foundation from which they cannot be displaced—e.g., the employment of diluents in fever, and of blood-letting in some forms of acute dropsy in young and strong persons by Hippocrates, of cold affusion in fever by Currie, &c. Still many remedies whose action we can in no way explain, and whose employment depends on tradition merely, do incalculable benefit, and we dare not deprive ourselves of the advantages of using them because we have not yet been favoured with a satisfactory explanation of their *modus operandi*. I need only recall to your memories such familiar drugs as iodide of potassium, colchicum, mercury, and quinine.

Partly from a daily increasing want of classical training, and partly from the necessity of paying some attention to the huge mass of modern literature, an acquaintance with the works of our predecessors is not so common in our profession as it used to be. I would therefore try to impress on you the vast importance of not neglecting this non-scientific element in our knowledge, and two or three instructive instances will not be out of place.

"Ipecacuanha, as a remedy for dysentery, was introduced into European practice in 1640, and its merits were then pointed out by the Brazilian traveller Marcgrav and the physician Piso; only in 1813 was it used in our Indian Medical Service, and it was again neglected. The Madras Medical Board in 1831 recommended it, and once more it was overlooked[*]; but now every army medical officer is taught to regard it as the most useful remedy—if not the only reliable one—in the treatment of a disease which, from 1842 to 1848 affected 1 in 8 of our troops in the Presidency of Madras, without mentioning its ravages in the rest of India, in China, and in West Africa. Peruvian bark even has been theoretically condemned, and so, according to Morton, "Oliver Cromwell died of an intermittent, because his physicians were too timid to make a trial of the bark, and although at first sold by the Jesuits for its weight of silver, yet about thirty years afterwards several thousand pounds of it lay at Piura and Payta without a purchaser."[†]

Again, Galen administered the root of the male fern in cases of tapeworm, and although for many centuries his doctrines and opinions held such universal sway over the medical world, that Massaria, a learned Professor of Pavia, as late as the sixteenth century, absolutely declared "that he would sooner err with Galen than be in the right with any other physician"; yet this useful remedy was lost sight of until Louis XV. purchased the knowledge thereof from Madame Nouffleur, a French empiric, who was retailing it as a secret nostrum for the cure of this disease.[*]

In this traditional element of our professional success every generation starts from a common platform, as far as the older drugs are concerned, and the later ones have a superiority only when new remedies are introduced, such as bromide of potassium or chloral hydrate. The importance of a teacher skilled in the *art* of therapeutics is here most manifest—one who does not slip into the easy groove of a routine practice, but who uses his drugs as Opie mixed his colours, "with brains, Sir." Herein also lies the advantage of a careful study of the works of the great masters of clinical medicine in all ages, from Hippocrates, Boerhaave, and Sydenham, down to Graves, Todd, Stokes, and Trousseau. They added a rational empiricism to careful observation, and allowed no foregone theoretic conclusions to prevent their employing any remedy whose merits had been proved by themselves or by their predecessors. "'Tis opportune to look back on old times and contemplate our forefathers. Great examples grow thin, and to be fetched from the passed world." As for ourselves, we may be sure that the new position of the advancing man has all the powers of the old.

I shall occupy your attention for a few minutes longer, whilst I point out, by way of contrast, the education that was considered necessary for an accomplished physician two centuries ago — such an education as a contemporary of Sydenham's would have had,—in order that we may appreciate at a glance the great care bestowed on it even at that time. We shall see, however, that it was entirely devoted to the cultivation of the observation, and that experimental investigations, morbid anatomy, and reasoning therefrom, were not then dreamt of.

"If now I describe, by way of advice to those that are entering upon the study of this Divine Art, the method of attaining to a point of excellency in it, that may serve our vulgar for a better rule, to distinguish their attainments by the course they have passed through. First, it's most necessarily requisite our young student should be perfectly instructed in the *Latin* and *Greek* tongues, being the universal keys to unlock all those Arts and Sciences, and no less a grace to the future physician. Secondly, being thus qualified for a student, he ought to apply himself close to the study of *Philosophy*, for which *Oxford* and *Cambridge* may justly challenge a præeminence above other Universities. But because according to the first Master, *Hippocrates, Art is long* and *Life is short*, he ought to ingage his Diligence, to absolve his philosophical course in two years at longest, and in the interim for his Recreations and Divertisements enter himself Scholar to the Gardener of the Physick Garden, to be acquainted with the fætures of Plants; but particularly with those that are familiarly præscribed by Practitioners, to prævent being outwitted by the Herb-women in the markets, and to enable him to give a better answer than it is storied once a Physician did, who having præscribed *Maiden-hair* in his bill, the Apothecary asked him which sort he meant; t'other replyed, some of the locks of a Virgin. Thirdly, supposing our Student to have made a sufficient progress in Philosophy, he may now pass to *Leyden*, and enter himself into a *Collegium Anatomicum*. A proficiency in that part fits him for a *Collegium Medicum Institutionum*, and afterwards for a *Collegium Practicum*, and then it's requisite he should embrace the opportunity of visiting the Sick in the Hospital twice a week with the Physick Professor, where he shall hear him examine those Patients, with all the exactness imaginable, and point at every Disease and its Symptoms as it were with his finger, and afterwards propose several cases upon those distempers, demanding from every Young Student his Opinion, and his grounds and reasons for it; withall requiring of him, what course of Physick ought to be præscribed. I must likewise advise our Student to take his lodgings there at an able Apothecaries' house, to contract the Knowledge of Drugs, and of preparing, dispensing, and mixing them into Compositions. In this course of Study, it would contribute to his future qualification, in sojourning a year with an experienced Manual Operator, without any hindrance to his other affair, and there by an Ocular inspection, and handling of all his Instruments, demanding their names, uses, and manner of using, withall by insinuations to visit his Chyrurgical patients, and see him dress them, and therefore would render his study in Chyrurgery plain and easier. These two years having given occasion to our Student to acquire a system and a brief compræhension of the Theory of Physick, and of the Practice likewise; nothing more remains than to amplifie his commenced Knowledge and Experience by his further Travails, to which end he takes his Journey to *Paris*, to be acquainted with the most famed Physicians, and informed in their way of Practice. The art of præparing Medicines Chymically, having merited a great esteem for its stupendious and admirable effects in the most despair'd Diseases, shews a necessity of being instructed in it, and therefore a Student may for the price of 3 pistols, purchase a most exact Skil in it, of one Mounsieur *Barlet*, if surviving. He must then go to *Montpelier*, and is supposed to merit the title of an able, experienced Physician, and to be raised far above those vulgar ones, that never felt the cold beyond the Chimneys of their homes. Six months at *Padua*, where he may justly aspire to a degree of *Doctor in Physick*, are to be succeeded by 3 months at *Bolongne*, six months at *Rome*, and then he should finally adorn the Intellectuals of the Physician by his Travails through several Countreys homewards. The vulgar will then be able to discern the difference between him and the ordinary Churchyard Physicians, who by their sordid deports and dangerous practice make it their business to ease the blind people of the weight in their pockets, and plunge 'em into worse diseases."*

[*] Report on the Progress and Condition of the Royal Gardens at Kew, 1870, p. 5.

[†] Paris, Pharmacologia, ed. ix.

[*] Paris, *vide supra*, p. 84.

Finally, gentlemen, if I have shadowed forth too high an ideal for our attainment, my excuse must be the lifelong nature of our education, the advantages of order, method, and a proper spirit in its pursuit, and the necessity of a never-ending patience for its consummation, remembering that he who never despairs seldom completely fails. "It is not proper," says Zoroaster, "to understand the intelligible with vehemence, but if you incline your mind you will apprehend it, not too earnestly, but by bringing a pure and inquiring eye." In the words of an ancient sage, you are "benefactors sent by the gods for the salvation of men; inattentive you will become their scourge"; and these words are, if possible, even more applicable now than in his days.

OF THE
INTRODUCTORY LECTURES
DELIVERED AT THE
MEDICAL SCHOOLS OF LONDON
AT THE
Opening of the Session 1875-76.

GUY'S HOSPITAL.

INTRODUCTORY LECTURE BY DR. STEVENSON.

THE lecturer took as his topic the study of medicine. He made reference to the varying esteem in which the profession had been regarded in different ages, and showed that it had not been invariably in periods of the greatest culture and enlightenment that its professors had been most honoured. Taking a hopeful view of the future, he combated the assertion of Dr. Gregory, which has recently been publicly referred to, that medicine will soon cease to be considered a liberal profession; and asserted that on the members of the profession it depends whether medicine shall be regarded as a liberal profession or not. Should gain, greed, and applause be the aims of our profession, the worst anticipations may be expected to be fulfilled; whilst if knowledge of disease, culture, and an honourable professional spirit be dominant the medical profession need not fear adverse criticism.

The qualifications necessary for the study of medicine were next touched upon, and thoroughness of study inculcated—the acquisition of accurate knowledge, and a sound judgment. In the acquisition of these the teacher can but assist, and the requisite opportunities being given it rests with the student to make right use of them.

In the more detailed exposition of his subject, Dr. Stevenson drew a distinction between the preliminary, and more scientific studies which first engage the attention of the student—the basis of medicine and the study of medicine proper (in which term are included medicine and surgery in all their branches).

When natural science first began to make rapid strides, too much was expected to be the immediate and direct result of scientific study; all our old notions were to be overturned and superseded. Such, however, has not been entirely the case; and now the mutual relations of science and medicine are perhaps better understood.

Anatomy, chemistry, and physiology were next considered, and then it was pointed out that these are ancillary to the study of clinical medicine, which, indeed, is to be the central object of the student. The mutual relations of patients and students were also dealt with.

The desirability of making a study of preventive medicine, and the use of statistics in determining the healthiness or unhealthiness of communities received notice, and it was urged that it should no longer be possible to say that medical men, as a rule, care nothing for sanitary science, and even view it with suspicion.

The system of stimulating students by prizes was also defended where not carried to excess; as also the moderate indulgence in manly sports. The lecturer concluded with an exhortation to the students manfully and at all times to do their duty to the profession and to their patients, and not to cease the study of medicine when a qualification to practise it had been obtained, but to make it a lifelong study.

ST. MARY'S HOSPITAL.

DR. RANDALL'S ADDRESS.

DR. RANDALL began by stating that as the advice given to those entering the profession had been wellnigh worn out, and addresses on medical education had been often published, he should venture to begin by touching on a hygienic subject, as a part of State medicine, before dealing with the ethics and mental discipline of student life: not on the air we breathe, the water we drink, nor the food we eat, but upon the productive earth, as health-giving and health-destroying, also as a purifier and preserver or antiseptic; more especially upon these last two qualities, in their sanitary relations to the burial of the dead.

Turning from grave to gay, Dr. Randall then addressed himself to those who were studying their profession, and more especially to those who were commencing. He exhorted them to consider well and reflect upon the exertions which would be required of them, and the amount of labour which was before them. They ought with a determined mind to fix their line of conduct, and to repeat "To be, or not to be; that is the question." Their answer should be a ready and quick one: To be what those who have brought them up and matured them expect them to be; what their teachers desire them to be; what their school for its honour and reputation demands them to be; and what their conscience tells them to be—diligent, hardworking, attentive, and determined students. He reminded them that they had passed the school of their boyhood, and were now entering that of their manhood, and that, the strict discipline of the school of their youth having ceased, they were now comparatively free agents, and their moral and mental discipline, regularity, and orderly conduct rested with themselves. Lecturers and tutors had been appointed to teach them, to assist, guide, advise, and encourage them; provision for studying and becoming acquainted with disease had been made for them. He said the trench had been mapped out and dug; "it is for you to lay the foundation, to lay a substantial and lasting one, to fill up this trench and raise it by degrees to a superstructure—a temple of knowledge, which it is true will take a period of four years to build, an apparently long time, therefore the more likely to be well and firmly built, and well furnished."

---

* The accomplisht Physician, the honest Apothecary, and the skilful Chyrurgeon, 1670, pp. 17 et seq.

He pointed out to young beginners the necessity of making a good start with anatomy, histology, and chemistry, and the advantages of thorough knowledge of each subject. He exhorted them in their moments of despondency and anxiety—for the most conscientious students were often the most anxious—to remember that determination and perseverance were more necessary for success that great talent or ability.

After strongly recommending the study of anatomy, which he said required attention, observation, and memory, he reverted to chemistry and natural philosophy. He believed that chemistry had of late years been neglected, and he said: "Chemistry has now become a most important element in your education; pray do not neglect it; without it you cannot study physiology advantageously, nor pathology, nor the principles upon which the treatment of many diseases is based. Under the present system of appointments, many or most of you may become sanitary officers, or have something to do with sanitation. Without you assiduously go through a regular course of the elements and theories of that science you will not comprehend its complications or be able to cope with future difficulties."

He advised the study of the laws of light, heat, and electricity, as this branch of physics had become a powerful factor in the treatment, diagnosis, and prognosis of disease. He illustrated this by different instruments now so much used, including the microscope, and clinical thermometer, which was an instrument as replete with safe diagnosis and prognosis as the stethoscope. Again, electricity and galvanism, which, as therapeutical agents, have made such rapid strides in the last few years, the beneficial effects of which as remedies for the relief of pain, and the restoring of a paralysed limb to use and feeling, or as stimulants, tonics, and sedatives, yes, even to the arresting of hæmorrhage and saving life, are now fully recognised.

"In the study of chemistry and physics the reasoning and calculating faculties will be brought out; you will have scratch and slate work; and thus, combined with those already mentioned in the study of anatomy, a training of the mind will be formed, a necessary training, and as good and efficacious as could be found in the mental training of the best of our educational bodies. Soon you will reach the wards of your hospital, there to learn and diligently watch the symptoms and signs of disease, the action of remedies, and the means adopted to relieve pain and to cure.

"You may rest assured that if you begin well and learn slowly and gradually and effectually, and are well grounded, you will attain your end, and enter life as an honest, efficient, and faithful practitioner. He who sows ought to reap; but if you have been idle and careless and inattentive, you will deeply repent of your conduct; you will have no confidence in yourself, nor be trusted by those who employ you:—

"'He that trusts you,
Where he should find you lions finds you hares;
Where foxes, geese. You are no surer, no!
Than is the coal of fire upon the ice,
Or hailstone in the sun.'

You will not have the boldness of the lion—that is, commendable assurance and reliance; nor the cunning of the fox—that is, wisdom, and aptness gained from knowledge; but truly you will be as timid as hares, and feel as foolish as geese; your reputation will be extinguished like the coal of fire upon the ice, or melt away like the hailstones in the sun."

He believed that there was a want of perfection in learning, and reminded them that the secret of being successful and accurate as students, next to perseverance, was the constant habit of reviewing the same subjects daily, weekly, and monthly.

In reviewing, he advised them to try to write what they remembered, "for the habit of writing, by which you attain a facility of describing accurately, is of paramount importance, not only for the sake of learning well, but also with the object of attaining that art for particular occasions, when your knowledge will have to be tested at the different examining boards and for competitive appointments. Remember that if Bacon said that 'reading makes a full man,' he also said that 'writing makes an exact man.'" The lecturer then earnestly recommended them not to enter into sports or games which would interfere with their attendance at lectures or more important instruction in the wards.

After some further remarks upon the line of conduct which the students ought to pursue during their studies, he in conclusion said: "Educate your mind to thoughtful and careful study; the training which you will thus acquire will render you more fit to gain that most important knowledge to be acquired at the bedside, it will tend to make you expert clinical observers and practitioners, the object of all your learning. Do not let this opportunity of acquiring knowledge pass by; do not let this vast field of information run to waste; store and husband it as you would the best riches of your professional life, and be assured it will form the backbone of a successful career in after days. And thus, session after session, if you feel that you have been a real worker, that you have employed your time diligently and assiduously, that you have used the abilities with which God has endowed you to the best advantage, to the satisfaction of your own conscience and to that of your teachers, you will possess such an inward feeling of comfort and of pleasant reflection, that you will be able to exclaim, with the French poet Lamartine:

"'Le jour s'est écoulé, comme fond dans la bouche
Un fruit délicieux sous le dent qui le touche,
Ne laissant après lui que parfum et saveur.
Oh, mon Dieu! que la terre est pleine de bonheur.'"

ST. THOMAS'S HOSPITAL.

INTRODUCTORY LECTURE BY J. F. PAYNE, M.B.

The lecturer commenced by stating that he should confine his remarks chiefly to the period of student life. This period involved interests quite sufficiently important to occupy the attention for at least one introductory lecture. The profession of a student ought not to be regarded as simply the commencement of a practical life; it had its own duties and its own dignities. Medical students did not always take an adequate view of their own position, and a little more of the *esprit de corps* which belongs to the students of English and foreign universities might be of considerable service. Indeed, the profession generally was not sufficiently alive to the relations which medical education ought to hold to the higher education of the country. It was unfortunate that local and historical circumstances had placed a gap between the old universities and the profession of medicine, which in other European countries did not exist. This gap could not be at once bridged over, but it was for students to remember that even if they did not form part of an academic body, they might cherish an academic spirit. One of the things that distinguished a true student from a mere craftsman was the endeavour to cultivate his mind. He should propose to himself to become not only well-informed in his profession, but a well-educated man. There were several means to this end—reading, conversation, travel; but, above all, proper use of professional training itself. It was a mistake to make too sharp a contrast between liberal and professional education. Really, the difference depended far less upon what was learnt than on the manner of learning it. Medical studies, properly understood, contained many of the elements of a true liberal education. The value of medical training as a liberal education depended chiefly upon its conneixon with the physical sciences. This was an enormous benefit to the medical student, and for the medical profession also it was of great importance to be allied with physical sciences. This would give it in the end the same kind of influence in society as the clerical and legal professions attained after the revival of learning by their possession of clerical scholarship. But medicine was not only allied with medical science. It had itself become embued with the scientific spirit, and was gradually, though not yet completely, brought up to the standard of the physical sciences proper. This scientific spirit, which it was the great merit of modern medicine to have adopted as its guide, was something not easily defined in words, but what it was could be clearly shown by contrasts in tracing the history of any branch of human knowledge. Nowhere was this more clear than in the history of medicine, which, as one of the most ancient of human pursuits, had survived many phases of intellectual development. Examples were quoted to show how in former times medical science was deficient in true scientific method; and how greatly modern physicians—though yet far from perfection—had improved in this respect. The sciences which medical students have to learn were then spoken of in more detail. It was shown that in anatomy and chemistry the student has types of the two chief divisions of science—the sciences of observation and those of experiment; while physiology, at present in a transitional state, was an example of the immense advantage of adding to pure observation experimental methods. It could not be too continually borne in mind that the subject matters of science consisted of material things, not of names or books. Yet books are quite indispensable in the present state of science to gain a knowledge of things, and their right use requires much discretion. For the beginner the best type of text-book is that which refers the student to the objects, and is useless without them. Fears are sometimes expressed lest the student of the present day should learn too much science, and become, as it is said, too scientific to be practical. But of true science it is impossible to have too much, and it is the most practical kind of knowledge that can be had. Too little science, or science of the wrong kind, is what makes men fail in practice. Equally mistaken is the notion that there is some kind of practical science less rigorous and difficult than genuine knowledge, which may be a chief substitute for it; but nothing of this can be of any use in the long run. Finally a word must be said about examinations. The present system had many evils, but in a practical profession, from which the public demand a guarantee of knowledge and capacity, some system was essential. The important thing for the student to remember was that examinations exist primarily for the benefit of those examined; and it was in a higher sense most important to the candidate himself to know whether he was fit to undertake the responsible duties of a medical practitioner.

DETAILS OF ELECTRICAL EXAMINATION AND TREATMENT IN A CASE OF PERIPHERAL PARALYSIS OF THE FACIAL AND OCULO-MOTOR NERVES.

By THOMAS BUZZARD, M.D., F.R.C.P.,
PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

How far the application of electricity is available in paralysis of the external muscles of the eyeball is a point upon which some doubt is still entertained. In the case which is here related, an unusual method of applying voltaism to these muscles was employed with success. Incidentally various points of great interest in reference to diagnosis as well as treatment arose in the course of the patient's illness, and the value of electrical tests was shown no less strikingly than the useful effects of voltaism in bringing back paralysed muscles to the influence of the will.

I was called in December, 1872, into the country by Dr. Playne, of Maidenhead, to see a gentleman sixty-two years of age under the following circumstances:—The patient looked somewhat older than his age, and had been more or less ailing for some years. A year previously he had suffered from some obscure mental symptoms, which had followed prolonged sleeplessness. He was usually dyspeptic, and had experienced pains of rheumatic character. On December 13th he found in the morning that on cleaning his teeth the water ran out of the right side of his mouth, and his face was observed to be drawn over to the left. Next day he could not close his right eye. When I saw him on December 17th, there was pronounced paralysis of the right portio dura. There was complete inability to close the right eye; the angle of the mouth dropped on the right side; in smiling the face was drawn over to the left; and when asked to show his teeth, the lips were scarcely separated on the right side, whilst on the left the teeth were exposed in the usual manner. The aperture of the mouth, under these circumstances, formed an irregular triangle with its base disposed vertically on the left side. The right eye was painful, and watering from exposure. If there was any impairment of sensibility to touch over the right side of the face it was very slight indeed. When the conjunctiva of the right eye was touched with the finger-point, avoiding the margin of the lid, although the pressure was perfectly well felt, there was no reflex closure of the lids.

Here, then, were the ordinary symptoms of a peripheral paralysis of the portio dura, and the fact that the patient had been out in his garden on the evening before his attack rather later than usual, and that the weather was cold and damp, combined towards the probability of his suffering from a rheumatic affection of the nerve, or at least from a condition referable to the influence of cold. The evidence so far appeared to point very strongly to a lesion which was peripheral, and comparatively free, therefore, from cause for anxiety. So, again, although there was some arcus senilis, there was no marked rigidity of the radial or temporal arteries, and no cardiac bruit; but, on the other hand, the patient had complained of some numbness in the left forefinger and thumb and a stinging sensation under one of his toes. (The description of this subjective symptom was vague, and it was impossible to make much of it.) The family history, too, was bad, and it was this which caused Dr. Playne some very natural anxiety when taken in connexion with the patient's symptoms. One brother, it seemed, had died of diabetes, and another had sugar in his urine at that very time. Now, the deep origin of the facial nerve is known to be situated in the floor of the fourth ventricle, and disease or injury of this region, as has been shown by Claude Bernard, is attended with the presence of sugar in the urine. Diabetes is a disease which is apt to show itself in several members of a family. The patient's two brothers were so affected, and he himself was suffering from a paralytic affection of a nerve which takes its rise in that portion of the central nervous system in which lesions are apt to be attended by the presence of sugar in the urine. These circumstances, as may be imagined, tended to throw a doubt upon the diagnosis which would not otherwise have been experienced. On the whole, however, taking into consideration the character of the affection, especially the completeness of the paralysis, my opinion was that the lesion was peripheral in situation. At that time I had not the opportunity, unfortunately, of applying any electric current, and was, therefore, without the most important means of diagnosis. It was agreed that the eye should be covered with a shade, that Dr. Playne should apply faradaism to the affected muscles and let me know the result, and that he should examine the urine for sugar.

On the 25th of January I learnt that there was no improvement in the power of the facial muscles, and that the current was felt much more strongly on the left than on the affected side. I was informed, too, that the urine, although its specific gravity was only from 1010 to 1015, contained traces of sugar when tested by Trommer's process. The general health remained as before; the patient was dyspeptic, and suffered from occasional vomiting. These details appeared to give a more serious complexion to the case, when taken in conjunction with the patient's history, and I felt disposed to doubt the correctness of the opinion I had given. The presence of sugar might point to disease of the medulla oblongata, and the impairment of sensibility of the skin on the right side of the face might signify a spread of the lesion to the sensory root of the fifth nerve.

On the 4th of March the patient came to London on a visit, and I saw him in consultation with Dr. Playne, who then left him in my hands. At that time the paralytic condition was more confirmed than ever; the right cheek was baggy and drooping; the saliva constantly ran out of the right angle of the mouth; the eyelids of the same side by a great effort could nearly be closed one-half, but that was all. In smiling, the face was greatly distorted, the mouth being rapidly carried away to the left; and the patient suffered much annoyance from inability to retain food and saliva in the right side of the mouth. Dr. Playne informed me that he had several times tested the urine for sugar, and had only once, about a month previously, failed to detect any. The test, he said, never indicated any large quantity. The volume of urine had been usually above the normal, on one occasion amounting to 96 oz.

I had now the desired opportunity of applying electrical tests. I found that neither faradaism nor the interrupted voltaic current would excite the right facial *nerve*. As regards the facial *muscles* of the right side there was no reaction to the strongest faradaic current which could be borne, but when I applied to them the rheophores connected with a Stöhrer's constant battery, using four cells only, and slowly intermitting the current, I obtained marked contraction of those situated about the angle of the mouth. A similar power applied in like manner to the muscles of the sound side of the face produced no reaction. The sensibility of the skin of the face was decidedly lowered on the right side, especially below the eye, both to touch and to the pain of faradaism. The latter fact was peculiarly well marked. The grasp of both hands was weak, but not definitely unequal, and the patient could raise either leg against pressure equally well. There was no marked impairment of sensibility in his hands, but on inquiry he said that there was slight numbness of the finger-points on both sides. There was no diminution in the power of tasting on the right side of the tongue. There was not then, and there had never been, any weakness in the external rectus muscle of the right eye. I examined the urine, which was pale, clear, acid, and of specific gravity 1013. It contained no trace of sugar nor of albumen. There was general derangement of the digestive functions, with a furred tongue and some diarrhœa. The patient was ordered a quarter of a grain of nitrate of silver, with one-fifth of a grain of opium, twice a day, and an effervescing mixture of citrate of potash and soda, with grain doses of iodide of potassium.

As regards the diagnosis, I thought there were sufficient grounds for believing that the lesion lay in some part of the course of the portio dura. Had it been at the deep origin of the nerve, it was unlikely that the sixth nerve, which (according to Lockhart Clarke) arises from the same nucleus as the facial in the floor of the fourth ventricle, would have remained unaffected. Moreover, and this was the most important feature, the electric reaction was distinctly that indicating peripheral paralysis. When the facial nerve is paralysed from central disease, it is, according to my experience, always the case that the facial muscles retain, either entirely or in great part, their power of being excited by faradaism. On the other hand, the absence of excitability by faradaism and the exaggerated influence of interrupted voltaism were completely characteristic of facial paralysis *à frigore*. I advised, and it was agreed, that treatment by interrupted voltaism should be employed.

On the 7th March, then, nearly three months after the seizure, this treatment was commenced, and afterwards continued almost daily for three weeks. Stöhrer's constant current battery was employed, at first four cells being engaged, then six, and finally eight. One rheophore was placed on the cheek at the point where the facial nerve breaks into its two great divisions, and the other at various parts of the face; but especially often near the ala of the nostril. The current thus employed caused vigorous contractions of many muscles affecting the nostril and mouth. At other times one rheophore was applied near the outer canthus, and then the current caused contractions of the orbicularis palpebrarum muscle. Each sitting occupied about twenty minutes. One rheophore was lifted and reapplied at tolerably regular intervals of about 30 or 40 in the minute. During the first week the change effected by this treatment, although at once apparent, was not very marked; but afterwards improvement was noticed daily. On March 28th, when the patient returned into the country, the cheek no longer bagged; the lower lip kept closed, instead of falling and showing, as it had done, the lining membrane, over which saliva trickled; the eye could be very nearly closed. Nor was this improvement altogether the result of a secondary contraction equivalent to that so often seen in the paralysed muscles in a case of hemiplegia, for a very considerable power of moving the mouth by voluntary effort returned. The nerve-twigs to the occipito-frontalis muscle must, I think, have escaped injury. At all events, when I tested the frontal part of this muscle a few days after beginning the treatment described, I found that it responded readily to the faradaic current when one rheophore was placed over the emergence of the portio dura and the other on the muscle. It was also capable of being contracted by voluntary effort.

On June 3rd I saw the patient again, and at that time a casual observer would have noticed but little deformity in his face. But I remarked a slight spasmodic jerking of the muscles of the affected side during facial movements, much as though the muscles, capable of being excited by volition, were not quite under control. At request he could close his eye, leaving only a very narrow aperture between the lids. Asked to show his teeth, the opening of the mouth was still triangular, instead of being more or less quadrilateral. During respiratory movements, little or no difference was perceptible in the action of the alæ nasi. Electrical testing now showed that neither interrupted voltaism nor faradaism produced contractions of the facial muscles.

In September I found that there was still some spasmodic jerking of the affected muscles. But, except when he laughed, it was difficult for an observer to believe that there was any great difference in power between the two sides of the face. Indeed the tendency, in consequence of the occasional jerking I have described, was to cause the idea that it was the left, not the right side of the face which was weakened.

Nearly two years had elapsed when I was again, on May 28th, 1875, summoned to see this patient. I found him in his bedroom, sitting up, with his back to the light, which his left eye was quite unable to tolerate. So much photophobia was there that I had to refrain from turning his face to the window whilst I examined him. The left eye was closed by ptosis of the upper lid, but the patient could, by a strong voluntary effort, open it, though the lid immediately afterwards fell. There was intense pain, referred to the ball of the eye, and also pain, together with tenderness on pressure, upon the left parietal bone, near its junction with the frontal. He had double vision, the images being crossed—that to his right belonging to his left eye. In order to avoid the confusion and giddiness caused by this diplopia, he was wearing a shade over the left eye. I found that there was partial paralysis of the branches of the left oculo-motor nerve, going to the levator palpebræ superioris, the internal, superior, and inferior rectus muscles. It seemed that the patient had been exposed to a great deal of domestic trouble and anxiety, with the result that his appetite and digestion had failed, and a few days before I saw him he had complained of double vision. It appeared also that several decayed teeth, which had been troubling him for some time, had interfered with his power of taking sufficient nourishment. I advised some chloride of ammonium, which seemed to have a good result as far as the pain in the eyeball was concerned. A fortnight later, however, I found that whilst he had ceased to feel pain in the globe of the eye, the paralysis of the muscles before referred to as partial had become complete. There was complete ptosis, and absolute inability to turn the left eye either upwards, downwards, or towards the nose. The symptoms indicating an affection of the left third nerve, which might be accompanied or caused by some effusion in its sheath, I advised a trial of iodide of potassium, although very doubtful whether it would be tolerated. In effect, the first dose so upset the patient's stomach that he could not be induced to try another, and Dr. Playne then prescribed some quinine, ammonia, and gentian. This answered very well; the appetite and general health improved, and when the patient came to town on July 7th, I found him looking much better than he had been. There was still, however, ptosis of the left eyelid. He could, when requested, lift the lid to a certain extent by a manifest effort, but it was immediately dropped. The vision of this eye not being absolutely occluded by the state of the lid, he was forced to cover it with a shade, as otherwise he was so embarrassed by diplopia that he could not walk without staggering. I found the recti muscles greatly wanting in power, but not, I think, quite so incapable as when I had last seen him. However, the eye was turned outwards constantly, and although by a strong voluntary effort it could be carried a very little way towards the nose, and a still less distance upwards and downwards, it was practically fixed in a condition of external strabismus, and was useless for optical purposes.

Guided by my experience of the result of interrupted voltaism in the facial paralysis of the opposite side of his face more than two years previously, I thought it likely, now that acute symptoms had subsided, that a similar mode of treatment might lead to good results in restoring the action of the muscles of the eyeball which were paralysed. Instructed, too, by former experience, I felt that faradaism was not the treatment proper for the condition. The muscles of the right side of the face had quite failed to respond to faradaism, but they were excited by a very mild voltaic current when it was slowly interrupted. So it seemed likely that a mild and interrupted voltaic current was indicated in the present condition. The best mode of applying this was not so evident. When metal rheophores covered with wetted kid were applied to the closed lids, and a current of varying strength employed, either the electric influence was unfelt or it was painful to the skin. There was difficulty, too, both with these rheophores and also with sponges in applying the stimulus exactly where I wished it. I now bethought me of using the finger as a rheophore, and tried it in the following manner. An assistant having applied to the patient's left temple a sponge rheophore connected with one (it was not material which) pole of a Stöhrer's constant current battery, I grasped in my left hand another sponge rheophore coming from the other pole, and then applied the forefinger of my right hand, covered with a single thickness of muslin wetted with pure water, to the right upper eyelid of the patient. The battery was Weiss's (Foveaux's), which had considerably run down, so that it was perhaps only half-strength. Cautiously increasing the number of cells (it was long before any electric sensation was felt), I found that the current from between 30 and 40 cells could be employed in this manner, my body, through which it was bound to pass, offering a great resistance, and serving indeed as a rheostat. The application was made through the closed lids. The finger proved an exceedingly convenient rheophore. I could apply exactly the amount of pressure desirable, and could reach portions of the globe which it would have been exceedingly difficult to act upon in any other manner. Moreover the strength of the current could be gauged at every instant. That which was employed was just sufficient to cause me to feel a distinct shock in the knuckle of my right forefinger every time the current was interrupted. Occasional flashes of light were observed by the patient, but he felt no pain. We thought we could see a little improvement in power after the first day's application, but there was no doubt of this at all at the close of the second sitting. Not to weary with a daily record, I may say that this treatment was applied on fifteen occasions in all, the applications extending over a period of three weeks. The time occupied at each sitting was from twenty to thirty minutes. A daily increase in power of the muscles was noted; and when the patient returned home, after the last application, he was absolutely well. The lid was entirely under control, and the movements of the left eye were in every respect perfect. Of course, therefore, there was no longer any double vision, and the use of the shade was discarded. The patient has since remained quite well.

Remarks.—I need scarcely say that it is a matter of the gravest import, as regards the prognosis, whether a paralysis of the facial muscles is diagnosed as peripheral or as depending on a lesion of the central nervous system. The importance of this is increased when the patient, as in this case, is a man who has passed the middle period of life; and becomes intensified when, as occurred in the instance which I have described, paralysis of one side of the face is followed by loss of power in certain muscles of the eye on the opposite side. The general conditions, the patient's age, his weak state of health, his family history,—all combine to give a very serious aspect to his case, which even his complete recovery would not of itself suffice to counterbalance. For it is quite conceivable that a man of this age, and with such a history, might suffer from a central nervous lesion, possibly involving small hæmorrhages, which could be repaired, and the paralytic symptoms be *ipso facto* removed, and yet that he might be left in a state peculiarly prone to the repetition of attacks which might at any moment involve districts where the occurrence of lesion would have a serious influence upon life. The mere fact, therefore, of this patient's complete recovery does not of itself bear conclusive testimony to the peripheral character of the affections from which he suffered. The electric reaction, however, of the facial muscles paralysed in the first attack, lends complementary evidence of a kind sufficient, I believe, to enable us to say that not only was that attack certainly dependent upon a lesion of some part of the facial nerve, not of the nervous centre, but that in all probability the second attack was of similar character. Experience, which by this time has been sufficiently universal to make its results positive, teaches us that when there is paralysis of facial muscles, and these a few hours after the attack show a diminution, rapidly going on to an entire abolition of contractility on exposure to induced currents, whilst contractility is effected with abnormal facility by the interrupted voltaic current, the lesion is not a central one, but involves some portion of the portio dura nerve. I have seen no exception to this rule. The lesion may result from cold, from wound of the nerve, or from compression, but it is always a lesion of the nerve, and not of the nervous centre. It was with great confidence, therefore, that when the test applications of the induced and voltaic currents in this case were followed by the results described, I pronounced the facial paralysis to be of peripheral origin. When, in process of time, the second attack occurred, involving on this occasion the oculo-motor nerve of the opposite side, although in the nature of things the application of electrical testing was not practicable, it was not unreasonable to infer that this also depended upon a similar cause to that which had caused facial paralysis two years previously, especially as isolated paralysis of one oculo-motor nerve is almost always peripheral. I ought especially to say that there was good reason to exclude the probability of syphilis in this case, and that there has not been any sign of gout. My prognosis was accordingly favourable, as regards the question of the site of the lesion, although I could not properly give any decided opinion upon the question whether the paralysis would be recovered from or remain permanent. I inclined, however, to the more favourable view, and thought that electrical treatment would be likely to assist recovery.

The voltaic instead of the faradaic current was chosen then, because the paralysis of the eye muscles, like that of the facial muscles, was deemed to be of peripheral character. It seems likely, especially from the researches of Schiff, that induced currents do not determine directly the contraction of muscles, but only act through the medium of the intra-muscular nerves. When these are damaged, as by the influence of cold, the power of causing contraction of the muscles by faradaism ceases. Not so, however, as regards the interrupted voltaic current, the influence of which is now much more marked than it is in healthy striated muscle. Dr. Onimus, of Paris, in some interesting papers which have lately appeared*, expresses the opinion that in cases of paralysis of the facial nerve the muscles, although they do not atrophy, pass into a condition in which the contractile substance resembles rather smooth muscular fibre or protoplasm than normal striated muscle. He reminds us that continuous currents have a much more marked action upon smooth fibres than induced currents, and to provoke the contraction of the unstriated fibres a current of much less intensity is required than for striated muscles. And as with normal smooth fibres so also with those striated fibres which, from an injury to the intra-muscular nerves, have acquired much of the character of smooth muscular fibre. In this mode Dr. Onimus explains the remarkable difference between the action of the induced current and that of voltaism in cases of facial paralysis, as well as the curious fact that the voltaic current acts much more energetically in such cases than in the healthy condition. In the case above related it seems probable that the branches of the portio dura distributed to the muscles, and not the trunk of the nerve itself, were affected. For the occipito-frontalis muscle escaped, and this omission, which is easily explained if the lesion be supposed to be located in a number of nervous twigs, some of which elude the hurtful influence, presents considerable difficulty if we imagine an injury to the trunk itself. Moreover, the sense of taste was preserved on the affected side, which suggests that the lesion was at least beyond the point where the chorda tympani is given off. The impairment of the cutaneous sensibility, which was certainly more marked than I am in the habit of finding it in such cases (there is often a little numbness), is probably to be explained by a localised influence upon the branches of the sensory nerve (fifth) similar to that exerted upon those of the portio dura. The exact effect upon the muscles, which was brought about rapidly by the influence of voltaism I do not find it easy to explain. It would seem—and this point is extremely interesting—that if we cut off the influence of the will from striated muscular fibre the structure tends to degrade, and, as regards its function, passes into a state closely resembling that which is characteristic of involuntary muscular fibre. The resemblance is threefold: the fibre is no longer contracted by the influence of the will, it is acted upon by voltaism when faradaism fails to affect it, and the action of voltaism upon it is much more marked than upon healthy striated muscle. Apparently the effect of applying voltaic currents to muscular fibre so degraded is to lead it back to its normal condition. It often happens, as it did in this case, that the will acquires its power to cause contraction of the recovering muscles before they will respond to the influence of the induced current, but after they have ceased to be abnormally excited by voltaism. When this occurs it is probably only a question of time as to when faradaism will be able to exert its ordinary stimulating power once more. When I last tested this gentleman's facial muscles, a few weeks ago, I found that voluntary power over them was restored perhaps to three-quarters of the normal extent, that interrupted voltaism affected the injured in no higher degree than the uninjured side, and that the influence of the induced current had again become manifest, though not quite perfectly. I suppose that voltaism replaced the action of the will, as far as concerned the preservation of the muscular fibres, till such time as the intra-muscular nerves had recovered and allowed the passage of the volitional influence. The circumstance that the face has not entirely recovered is, doubtless, owing to the injury to some of the muscular nerves having been irreparable. There is nothing, it seems to me, in such examples as this, which requires one to fall back upon an electrolytic action of voltaism upon the constituents of the nerve-trunk to account for phenomena which are to be explained more easily in the manner described. I think that the very rapid clearing up of the oculo-motor palsy (in the second attack) under the influence of voltaism goes far to prove that the lesion in this, as in the other paralytic seizure was of a superficial character. The injury at the time electrical treatment was commenced was probably to a great extent repaired, but the muscles which had been cut off for a long time from the stimulating influence of the will had degraded into a state approaching that of involuntary muscular fibre, and were incapable therefore of being acted upon by volition to any effective purpose. The few applications of voltaism restored the muscular fibres to their natural condition, and they became both physically and metaphysically "voluntary."

---

* Practitioner, September, 1874, June and August, 1875.

The use of the hand as a rheophore is not new. It has been employed by many for the application of faradaism, especially to the spinal column. But, as far as I am aware, the use of the finger in the manner described for applying interrupted voltaism to the eye muscles is novel. It is certainly very convenient. What we want in such a case is a large quantity of electricity of low tension, and this is, I think, especially well arrived at by interposing the operator's body in the course of the current, and employing a considerable number of cells.

ON THE NEGLECT OF MINOR SURGICAL OPERATIONS.

By SAMPSON GAMGEE, F.R.S.E.,
SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

The inclination, natural to many men, to defer matters which are not urgent, and to pride themselves on inaction as evidence of caution, is the cause of a great deal of mental anxiety and physical trouble in all walks of life—in surgery especially. It is open to question whether more mischief is done by men who are always ready for prompt and decisive action, regardless of risk, or by those who never tire of discussing probabilities, and shrink from coming to any decision at all if in doing so their reputation be in any degree imperilled. Certain it is, in the matter of surgical operations, that if a good deal of harm result from their unnecessary performance, much pain and distressing inconvenience might be spared, to say nothing of life prolonged, if some minor surgical operation had been timely performed.

These reflections have been recalled by a study of Sir James Paget's chapter on the Calamities of Surgery, in his recently published Clinical Lectures and Essays. He lays down the rule (p. 68), "Never do an operation if you can cure the patient by any reasonable method or other means." This proposition seems to command obvious assent, independently of the high claims to respect derived from its authorship. But when Sir James proceeds to illustrate his rule, I fear he is supplying the unreasoning opponents of operations with instances and arguments which, under cover of his influence, may be productive of unforeseen results. The fact is that in a very large number of cases in which so-called palliatives are resorted to, an operation is not only the most reasonable method of cure, but the least painful; at once the most creditable to the surgeon, and to the patient the most economical in the broad sense of that term.

When a varicocele is large, oppressing by its dragging weight, and causing, as it sometimes does, atrophy of the testicle, trusses, rings, and all such expedients are of little or no practical use; whereas the radical cure, now that the efficiency and simplicity of the elastic ligature are understood, can be carried out with very little pain, with scarcely any confinement, and with perfect success.

A stricture of the urethra is the only ailment of many men, who are either for years unconscious of its existence, or are the patient objects of palliative measures, in spite of which the stream becomes smaller and more twisted. How easy and effectual is timely dilatation; how little trouble is it for the patient himself to maintain the freedom of the passage by passing at intervals a good-sized elastic bougie. A neglected stricture is the source of infinite trouble to many men, and is one of the most frequent causes of premature decay and death, which timely and well-executed catheterism is practically all-powerful in preventing.

A tendency to hæmorrhoids and their actual existence, doubtless, admits of relief by strict observance of dietetic rules, proper exercise, and ablutions. But when the piles have acquired shape and the solidity of age, the radical cure is the only effectual relief. Take the simple and not unfrequent case of a solitary external pile, sometimes causing little, often much, trouble. Its excision, under the ether spray, is absolutely painless; and if the bleeding spot be touched with a little styptic colloid, the patient may go about his business at once without fear of consequences.

The elongated uvula, which troubles many orators and vocal artists, grows longer and more troublesome in spite of astringent lozenges and gargles. Its removal at just length with a pair of scissors is as nearly painless as can be possibly conceived, and is a lasting source of comfort. But of all conditions in which the superior economy of operative interference over miscalled palliatives is demonstrable, none is so striking as chronic enlargement of the tonsils. Many children with pale faces and depressed chests, who speak thickly and snore in their sleep, have big solid tonsils, which nearly touch in the middle line. It is beautiful to watch, in the course of a very few days, the cheeks becoming rosy and plump, and the chest expanding, after excision of the tonsils with the simple throat-guillotine,* which, in children and adults, is one of the most useful, yet insufficiently practised, operations. Doubtless the great question is when to interfere and when to abstain. That can only be solved by well-balanced judgment based on ample information, neither stimulated by ambition for dexterous display, nor checked by diffidence, which so frequently proclaims itself as the laboured outcome of philosophical caution, when it is in reality the natural offspring of constitutional indecision.

Birmingham.

---

* Two very striking cyrtometrical observations in point are given by Dr. Norman Moore in St. Bartholomew's Hospital Reports (London, 1874, p. 129).

ON THE

TREATMENT OF SOME CHRONIC UTERINE DISEASES BY MINERAL WATERS AND OTHER REMEDIES.

By THOMAS MORE MADDEN, M.D., M.R.I.A.,
LATELY EXAMINER IN MIDWIFERY AND THE DISEASES OF WOMEN, QUEEN'S UNIVERSITY, IRELAND; PHYSICIAN TO ST. JOSEPH'S HOSPITAL FOR CHILDREN, ETC.

Almost all chronic diseases from which women suffer are now commonly ascribed to the uterus, and supposed to require only uterine treatment. I have elsewhere shown the constitutional nature of many of these complaints. But as this is practically ignored, I again venture to urge the importance of constitutional remedies in such cases, and also propose to describe some mineral waters especially applicable for their cure.

Every age has its prevailing fashions in medicine as certainly as in dress or in manners; and in many instances, after long periods of oblivion, the theories and practices of our predecessors are revived as new discoveries. Thus at present the diseases and displacements of the uterus occupy the most prominent place in the supposed causation of all the diseases of women. For modern gynæcologists, having re-discovered the use of the ancient διοπτρα, and disinterred the old aphorism, "*Propter uterum est mulier,*" now employ that instrument in all possible cases, and reiterate or expound this text, in accordance with their own views, with all the enthusiasm of recent conversion.

The apparent increase of uterine maladies may in some measure be accounted for by the improved methods of diagnosis now resorted to in such cases. Nor, in considering the causes of the sudden prevalence of the novel complaints which fill the pages of some gynæcological writers, should it be forgotten that the symptoms of diseases formerly as well known and treated under more homely names are frequently re-described in modern pseudo-scientific terms as something new. Some of the polysyllabic words thus employed remind one irresistibly of that "patched and piebald language" of which Hudibras

> "——— had supplies so vast and large.
> For he could coin or counterfit
> New words with little or no wit;
> Words so debased and hard, no stone
> Was hard enough to touch them on:
> And when with hasty noise he spoke 'em
> The ignorant for current took 'em."

Irrespective, however, of their being in vogue and better diagnosed than formerly, uterine diseases must be admitted to be more prevalent. This is chiefly due to the increasing luxury of the age and the more artificial habits and conditions of modern life, producing gout and, indirectly, scrofula —the most common, although generally unrecognised, causes of disease affecting the female reproductive system.

The chronic character of many of the diseases peculiar to women and their proneness to recur after their supposed cure is the result of the general reliance on local remedies, by which their symptoms are mitigated whilst their causes are neglected. Thus congestion or ulceration of the cervix uteri is usually treated only by astringent injections and caustics. In like manner, the various displacements and flexions of the uterus are by many supposed to require nothing beyond the mechanical support of a properly adjusted pessary for their cure. But congestion of the cervix leading to ulceration, and hypertrophy of the fundus uteri occasioning displacements, usually result from chronic inflammation of constitutional origin; and hence caustics and astringents in the former or pessaries in the latter are *per se* mere palliatives, although in appropriate cases both are invaluable and indispensable adjuvants. The vaginal speculum, however necessary in the treatment of many uterine diseases, is far too indiscriminately resorted to in complaints on which its use can throw no light, and in others the cure of which is retarded by its employment. When unnecessary, this must increase any existing irritation of the parts and also keep up that morbid concentration of the patient's mind on the imagined seat of her malady by which a nervous woman can create for herself all the subjective symptoms of any disease. I have had occasion to use the speculum extensively and daily for many years; but I have never thought its employment justifiable as a matter of routine practice, nor, especially in the case of unmarried women, without absolute and well-proved necessity.

The majority of uterine specialists may be considered as followers of one or other of three distinct schools of gynæcology. A few years ago most of the diseases peculiar to women were commonly attributed to inflammation of the cervix uteri; then newer views as to the frequency and pathological importance of ovarian disease in such cases prevailed; and, lastly, the doctrine that these complaints are the result of displacements and flexions of the uterus has come to be adopted as the only sure foundation of uterine therapeutics;

> "For in physic, as in fashion, we find
> The newest has always the run of mankind."

Each of these theories is undoubtedly applicable in many instances, but neither of them holds that exclusive and primary place in the causation of the diseases peculiar to women which some writers insist on.

As far as my own experience allows me to form an opinion, I would say that the most frequent uterine or periuterine cause of impaired health is chronic inflammation of the uterus and its appendages. At the Dispensary for Diseases of Women rather more than one-tenth of the patients under my care suffered from chronic endometritis or cervicitis. In some cases chronic metritis occasions congestion of the cervix; in others it results in hypertrophy of the fundus, eventually causing flexions or displacements; in others, again, it extends to the ovaries, producing menstrual derangements, hysteria, and sterility.

It is surely obvious that a part so intimately connected by structural and sympathetic relations with the other great organs as the uterus cannot possibly suffer any serious interference with its sanitary integrity without affecting the general health. Hence, even if uterine disorders did not originate from constitutional predisposing causes, they must produce constitutional effects and be under the influence of constitutional treatment.

Of the predisposing causes of chronic inflammation of the uterus, by far the most frequent is the scrofulous diathesis. Some years ago I observed, and called attention to the fact, that a large proportion of the patients attending the Dispensary for Diseases of Women were of a well-marked strumous habit of body, or actually suffered from glandular or cutaneous scrofulous affections. In such cases uterine complaints are necessarily impressed with the constitutional taint. Thus, for instance, scrofulous endometritis bears the closest resemblance, in its course, in the peculiar glairy discharge, and other symptoms, to chronic nasal catarrh of scrofulous patients. The granular condition of the uterine mucous membrane is precisely similar to that observed in the conjunctiva in scrofulous phlyctenular ophthalmia. In most cases abrasions and ulcerations of the os and cervix uteri, like other scrofulous sores, are superficial, circular, pale, and indolent, possessing little sensibility, although occasionally irritable; chronic to a degree when either maltreated or neglected, but readily curable when suitable local applications are used conjointly with the constitutional remedies indicated in all scrofulous diseases.

Secondary syphilis is the least common of the constitutional causes of subacute metritis and its effects. In cases of chronic uterine catarrh and abrasion of the os uteri of this kind, the diagnosis is by no means easy; nor is the peculiar vitreous or mottled appearance of the cervix described by some at all pathognomonic of syphilitic cachexia.

Women are supposed to be in a great measure exempt from gout. This opinion, although it may be correct with regard to podagra, is certainly unfounded with regard to anomalous gout, which attacks women quite as much as men; and, in the former, affects the uterus as commonly as regular gout does the joints in the latter. There is no reason why the gouty diathesis should be confined to men. Gouty parents generate female as well as male children: any hereditary disposition must be shared in by both alike, and the exciting causes of the disease are obviously not limited to either sex.

Many of the symptoms which Gooch described under the name of irritable uterus, and which modern gynæcologists have transferred to the account of displacements of that organ, are oftentimes produced by gout, and may occur independently of any mechanical cause, though they may also coexist with it. I have at present under my care a widow lady, aged about thirty, who had for years been suffering from lumbar and pelvic pain extending down the left thigh, and accompanied with lameness, dysuria, and slight uterine catarrh. The cervix uteri was congested and the os patulous, the sound penetrated five inches, and the fundus was tilted backwards. Before she consulted me she had been treated by others for retroversion by mechanical expedients only, and for a long time I did the same. Every pessary—and the number was almost countless that I tried,—however well it might fit, was practically useless: before a week's time she would limp into my study in as bad a plight as ever. I need not go through the details of the case further than to add that I learned at last that she inherited gout, and, on examining, found her urine laden with uric acid. She was then treated by alkaline remedies and colchicum, sent to Vichy, and has returned with all the symptoms relieved, and, though yet necessitated to wear a Hodge's pessary, is practically free from any discomfort.

With regard to active local treatment in ordinary cases of chronic inflammation and simple ulceration of the os and cervix uteri, Talleyrand's advice to a young diplomatist might be advantageously adopted by gynæcologists—"Surtout point de zèle." If we trusted more to nature in such cases, I verily believe that in most instances our patients would get well sooner than if the local irritation be increased *secundum artem* by almost daily examinations and the repeated application of escharotics. I have, again and again, seen simple abrasions or ulcerations of the cervix uteri cured without any topical treatment whatever; and in other instances cervical ulcerations of long standing were healed, and hypertrophies of the cervix which had resisted the use of the potassa fusa, potassa cum calce, and other violent remedies which had been previously employed by bolder practitioners, were reduced by the use of a strong solution of iodine in glycerine or spirit, or nitrate of silver, combined, of course, with constitutional treatment. In such cases, too, I always rely in great measure on the effects of emollient or medicated tepid vaginal irrigations. For this purpose the ordinary vaginal syringe is always an imperfect and useless, nay, in some cases even a dangerous instrument. I therefore always recommend the use of an irrigator such as that which I exhibited to the Obstetrical Society some time since. The instrument is very portable, can be readily used, and is capable of impelling a gentle continuous stream of plain or medicated water into the vagina for any length of time, and in any position the patient desires, without causing the least fatigue.

Before considering the uses of mineral waters in cases of impaired health connected with chronic inflammation of the uterus and its appendages, we should in the first place recognise the fact that in such cases local treatment, although not to be neglected, should be subordinate to the cure of the constitutional disease which is the remote, and too commonly the undetected, cause of the local complaint. Thus, in cases of scrofulous disease of the cervix uteri, in addition to the obvious hygienic and dietetic means required by all strumous patients, the faulty state of the blood must be corrected by alteratives and tonics—cod-liver oil, small doses of metallic iodine, Blancard's pills, and the syrup of the iodide of iron, and, above all, by the natural chalybeate and iodated mineral waters. In like manner, in instances of uterine irritation occurring in gouty patients our treatment should be primarily directed to the diathetic predisposing cause, and not, as is too generally the case, merely to the predominant local symptoms. It is utterly impossible to cure gouty inflammation of the uterus without constitutional treatment. There is never any difficulty in inducing valetudinarian ladies to take any quantity of medicine, and, as a rule, women bear colchicum and other remedies for gout fully as well as men. But it is by no means so easy to persuade a patient suffering from gouty endometritis, who has long been treated by local measures only, conjoined with a stimulating and nutritious regimen to keep up her strength, that her disease is the result of long indulgence in a diet beyond all proportion to the wants of her system, late hours, and little active open-air exercise. Nor in such cases is the patient always disposed to thank the physician who honestly tells her—

> "Si tibi deficiant medici, medici tibi fiant
> Hæc tria: mens læta, requies, moderata dieta."

Hysteria in some form is generally associated with chronic uterine disease, and this underlies and complicates most of the symptoms for which gynæcologists are consulted. Counterfeiting every malady, acting through and upon the nervous system, attended with groundless apprehension, depression of spirits, and morbid irritability of temper, oftentimes rendering the patient herself as miserable as she renders those about her, this disease is closely allied to that graver nervous lesion which constitutes insanity, and, if unchecked, may pass into it. Local treatment, except to rectify some displacement or subdue some well-marked ovarian or uterine inflammation, is of little utility in such cases; nor are the tonics and antispasmodics usually relied on comparable, in their therapeutical effects in restoring a hysterical woman to the *mens sana in corpore sano*, to the saline chalybeate water, such as Ems, Schwalbach, or Spa, provided these be used at their source.

"There is," says Burton, "no better physic for a melancholy man than change of air and variety of places." And this physic we prescribe when we order our hysterical patients to any continental watering place. The use of some remote spa is something beyond the effect of the medicated water we have recommended. It necessitates what is of far greater service than any physical remedy in such cases—namely, the moral benefit of change of scene, of occupation, and mode of living. The functions of the liver and bowels, commonly torpid in hysterical women, are stimulated by the change of living, and a sedative effect is generally produced on the hyperæsthetic condition of the patient. The changes and incidents of the journey suggest new thought, by which the patient's mind is diverted from that morbid concentration on her ailment which characterises utero-hysteric disease, and ceasing to dwell on her symptoms, they cease to exist; in other words, she is cured.

The benefits derived from the use of mineral waters in the chronic diseases peculiar to women are by no means limited to the moral effects just referred to. In many of these spas we have medico-chemical agents of extraordinary therapeutic power, and in the next paper I propose to point out the special application of some of these in the constitutional treatment of chronic inflammation of the uterus and its complications.

(*To be continued.*)

INTRA-CRANIAL ANEURISM.

BY WILLIAM E. HUMBLE, M.D. LOND.

THE rarity of cases of intra-cranial aneurism diagnosed during life induces me to forward an account of a case now under my care. And I do so at the present time, rather than wait for the ultimate issue of the case, in order to draw attention to the importance of practising auscultation of the head more frequently than we are in the habit of doing.

So far as I can find, there are but two cases on record in which intra-cranial aneurism has been diagnosed during life—one by Mr. Coe, of Bristol, in which the carotid artery was tied successfully; and the other by Mr. Jonathan Hutchinson, who related the case at the Clinical Society on the 9th of April, 1875, and in which a spontaneous cure occurred by consolidation of the aneurism, as demonstrated by examination after death from another cause. Mr. Holmes in his lectures on Aneurism refers to Mr. Coe's case, and in the same lecture relates another case of intra-cranial aneurism which was for a long time under observation, but in which auscultation was unfortunately not practised, and the disease not diagnosed during life.

Mr. Holmes says:—"We know nothing at present of the diagnosis of intra-cranial aneurism, so that no treatment can as yet be directed specially to it. And, looking at the very free intercommunication of the four large trunks which nourish the brain, it seems unlikely that surgical measures directed to any one of them would procure the consolidation of an aneurism situated on one of its main branches." I think that a careful consideration of Mr. Coe's and Mr. Hutchinson's cases together with that I am about to relate, and the clearly defined symptoms in each of them, may perhaps lead us to look more favourably upon the possibility of diagnosing this disease within the head.

Mrs. ——, a lady aged forty, has had a family of several children, the youngest is seven and a half years old. During the last two or three years she has been getting much stouter, having previously been rather thin. Her habits of life have been active and regular. Has been subject for several years to severe attacks of hysteria, so severe as even to threaten the intellectual faculties, and was the subject of one of these attacks about a year and a half ago, since which time she has been quite free from them and her mind tranquil. Her parents are both alive and there does not appear to be any hereditary predisposition beyond gout, to which her father is subject; has not herself suffered from gout or rheumatic fever, or other constitutional affection. Has not received any injury to the head, except that about ten years ago she struck her head rather severely with the bough of a tree.

In March, 1875, she suffered, as did also the children, from an attack of epidemic febricula, and while labouring under it was seized with severe neuralgia of the right brow and adjacent region. The pain was constant, but with severe exacerbations. She also complained of some indistinctness of vision, with slight diplopia, but without perceptible squint. The neuralgia was much relieved by local application of aconite and chloroform, and after a short time disappeared. She never, however, lost the double vision. About the middle of May she told me she was still suffering from the disturbance of sight, and there was also some amount of photophobia, with slight contraction of pupil, especially of the right eye. There was also observed a decided though slight squint inwards of the right eye. Under the use of belladonna collyrium she was much relieved as regarded the photophobia, but the squint continued to increase, and became very decided. The power of the external rectus muscle was not quite lost, and she could by an effort of the will still direct the eye to some extent outwards. She also complained of a constant loud noise in the head. I ventured now to state to the patient that I had reason to fear that a tumour of some kind existed at the base of the brain, and recommended the occasional application of leeches to the temple, blistering behind the ear, &c. This plan was adopted, and she was also put gently under the influence of mercury, keeping the gums just tender for a week or two. The squint continued, although it certainly became less, and on the whole she thought herself better; but the noise in the head continued as loud as ever, and was a serious inconvenience to her, and not at all relieved by the bleeding from the leeches. Her indistinctness of vision also continued, though rather lessened in degree.

About this time she mentioned to me, as a curious circumstance, that her children said they could hear the noise in her head when they placed their heads against hers. On applying the stethoscope to the head I at once heard a rather loud systolic bruit accompanying each pulsation of the heart. The sound was of a blowing character, and was heard loudest over the right temple just above the anterior inferior angle of the parietal bone, thence diminishing in loudness to the vertex, and again louder at the corresponding part of the left side of the head, where it was nearly as loud as on the right side, though to my ear it seemed rather more distant. The sound is heard by the patient loud in the right ear and not in the left. The rapidity and loudness of the murmur are increased both to the patient and the auscultator by exertion or whatever excites the circulation. I was now convinced I had to do with a case of intra-cranial aneurism, probably of the internal carotid artery at the cavernous sinus, which by its pressure on the sixth nerve caused the strabismus, and had caused the neuralgic pains connected with the fifth. The convection of the sound so clearly to the two sides of the head was at once accounted for. I explained the nature of the case generally to my patient, and told her that I was of opinion that the operation of ligature of the carotid should be performed. On the 25th of June I had the pleasure of meeting in consultation Dr. Lush, of Weymouth, who, after a careful examination of the patient, agreed with me in every respect as to the diagnosis and treatment proposed.

My notes at that time state that her health is, except as regards the local symptoms, generally good. She says she has occasional feelings of sickness. Appetite good; bowels regular. There is no valvular murmur heard over the base of the heart, nor any systolic bruit in the neck. A musical venous murmur is heard at the base of the neck, but only produced by a certain amount of pressure with the stethoscope. An attempt was made to stop the noise in the head by pressure on the common carotid, but in consequence of the shortness and stoutness of the patient's neck it was not found possible with any moderate amount of pressure to compress the artery sufficiently effectually to stop the pulsations or the aneurismal sound in the head. She sleeps well, and in fact is more inclined to sleep than usual, at times almost falling asleep in the daytime. The special senses are not affected, except vision slightly. There is no paralysis of either of the extremities, though she has been subject to occasional numbness of the fingers. Catamenia regular.

Ligation of the carotid has been declined by the patient, at least for the present. Mr. Tufnell's plan, by absolute recumbency and restricted diet, was then urged strongly, but with no better success, so far as concerned a fair and full trial of the plan; and I then determined on adopting the means so strongly advocated by Dr. Balfour for thoracic aneurisms. That plan is now being carried out, and I propose at a future time supplementing this communication by another recording the treatment and its results, with such further information as may be obtained in the progress of the case.

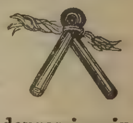
LONDON HOSPITAL.

CASES OF FISTULA IN ANO.

(Under the care of Mr. MAUNDER.)

WE are indebted to Mr. J. Job, house-surgeon, for this report of some severe cases of fistula in ano.

CASE 1.—M. A. W——, about twenty-four years of age, a married woman in fair health, was found, on examination, to be affected with a fistula in ano on both sides of the anus. Mr. Maunder treated one fistula in the usual way by incision with the knife, and to the other he applied the elastic ligature. The operations were performed on March 10th, 1875. On the twenty-third day after the operation the knife wound was found to be healed; but not until the sixty-first day subsequent to operation was the ligature wound cicatrised. During the first few days a good deal of pain was felt at the seat of ligature, which came away, as it is shown in the drawing, on the tenth day. The little rounded head with a depression in the centre originally enclosed the tissues to be divided.



CASE 2.—J. H——, aged thirty-three, admitted May 3rd, 1875, with a fistula on the right side of the anus. On examination it was found to be about five inches in length, but with an intervening opening just within the sphincter. The most accessible portion of the fistula was laid open with a bistoury, while the rest of it was cut up with a pair of common scissors, the pointed blade of which traversed the canal, guided by a director, the bowel being protected from the second blade, and the progress of the operation ascertained by the left forefinger introduced into the rectum.

During the progress of the case a small abscess formed in the buttock, towards the perineum, which required evacuation. Notwithstanding this complication, and the great length of the sinus, the patient made a good recovery, and has remained well.

CASE 3.—E. M——, sixty-five years of age, admitted May 21st, 1875, was also the subject of a fistulous opening on the right side of the anus. On examination, a very long fistula was found, passing to the left of the vagina, and apparently terminating behind and on the left side of the symphysis pubis. No bare bone could be detected. An intervening opening into the rectum just within the sphincter existed.

Mr. Maunder declined to lay open so extensive a fistula, and explained to the patient that he could not undertake to cure her absolutely, but might be able by operation to prevent the constant discharge at the external orifice of the fistula, which was in itself a great source of annoyance and discomfort. He proposed to lay open that portion of the sinus which existed between the external orifice and the opening just within the sphincter; leaving the rest of the sinus to empty its secretion into the bowel, to be discharged at stool.

The desired object was attained by the operation.

SOUTH LONDON OPHTHALMIC HOSPITAL.

EMBOLISM OF BRANCHES OF THE ARTERIA CENTRALIS RETINÆ WITHIN THE EYE; WITH REMARKS.

(Under the care of Mr. Edward Nettleship.)

Several cases of embolism of one or more intraocular branches of the central artery of the retina have been recorded (Sämisch, Hirschmann, Barkar, and Knapp, and others). They are still, however, among the uncommon cases in ophthalmic literature, and additional instances still have interest enough to justify a record, while the case given below admits of useful comparison in several points with those already published, notwithstanding Knapp's able *résumé* of the subject.*

Bessie T——, a very intelligent girl of sixteen, whilst dressing one morning about June, 1874, suddenly found that her sight was becoming defective. On trying each eye separately she found that when she covered the right the left was "quite blind"—i. e., she was "in total darkness." In a short time the sight began to return, and before long, she thinks within twenty-four hours of the failure, she could see as well as when Mr. Nettleship first saw her six weeks later. She described the sight as returning first in the middle of the visual field; a small point of light "like a pea," which gradually enlarged. She came to the hospital on August 5th, 1874, complaining of defect of the left eye, when Mr. Nettleship found that she could see nothing in the outer, upper, and upper-inner parts of the visual field; but that sight was good elsewhere, and direct vision perfect, so that she read No. 1 Jaeger and 20 Snellen at 20 ft. The sight and visual field of the other eye were perfect.

Ophthalmoscopic examination of the defective eye disclosed a slight milky haziness of the (real) lower part of the retina, the upper boundary of which on the yellow-spot side of the disc formed an abrupt horizontal line running outwards from the lower edge of the disc below the yellow spot itself, which was thus intact; on the nasal side of the disc no such abrupt distinction between healthy and diseased parts was discernible. The disc was considerably paler than that of the other eye, and the retinal arteries, especially the (real) lower branches, were considerably diminished in size. There were two small round spots of black pigment in the lower part of the fundus at some distance from the optic disc.

The true nature of the case did not occur to Mr. Nettleship until he had examined the case several times, and it was treated for some months as an obscure retino-choroiditis, there being nothing in the girl's appearance or family history to suggest any probable explanation.

Three months later (Oct. 31st) she considered that the field of vision had enlarged somewhat, but, on measurement, this was very doubtful. There was still slight milkiness of the retina, and the other appearances were the same as at the first examination. On July 6th, 1875, about thirteen months after the failure of sight, the visual field, taken at a foot from the patient's eye, measured only an inch upwards, and three or four inches to the temporal side of the centre, while below and to the nasal side it was of full size. She had no perception of objects whatever in the defective parts of the field, but suddenly saw them quite distinctly as soon as they came within the above limits. Ophthalmoscopic examination (both of the erect and inverted image) showed the same marked pallor of the optic disc as before, while on careful inspection of the vessels it was found that the (real) lower divisions of the artery (two or three in number) were so extremely diminished that they could not be traced beyond the lower border of the disc; some hazy, thin, white lines in the lower part of the retina near the disc were probably the obliterated remains of these arteries, but with an undilated pupil this point could not be determined with certainty. The small arterial branches running straight outwards to the yellow-spot region were unaltered. The retinal veins were rather small. The effect of pressure on the eyeball as a test of the circulation in the arteries was unfortunately omitted.

A doubtful systolic bruit was heard over the base of the heart. She had never had rheumatic fever, but her father was subject to "chalk-gout." She now stated that for some little time before the sudden failure of sight she used to have "momentary" attacks of a curious feeling, during which the objects she was looking at seemed to "rise up"; it was not "double vision," and was not "giddiness," although she said she would have fallen during the attacks had she not held on to a support.

The ophthalmoscopic appearances, taken with the history of the case and the ascertained character and position of the visual defect, leave no room for doubt, in Mr. Nettleship's opinion, that this was a case of embolic obstruction of the lower and inner divisions of the arteria centralis retinæ, the upper divisions and the small branches to the yellow-spot region remaining pervious. The two spots of pigment in the fundus were doubtless the remains of hæmorrhages.

Mr. Nettleship remarks that in several cases of embolism of branches of the arteria centralis the first symptom has been obscuration of the whole visual field, amounting either to total blindness or general haze. In his case the girl said she was in total darkness with the affected eye for about an hour, after which the sight quickly and completely returned in the unaffected part of the field. In one of Knapp's cases recovery was also very complete and rapid in the unaffected part, while in two others the improvement was spread over several weeks, and the parts supplied by still pervious branches never perfectly recovered. It appears, as Knapp has pointed out, that the part of the retina supplied by the blocked branch or branches never recovers in the least; in each of the seven cases, as in his own, the corresponding part of the visual field was entirely wanting, the boundaries of the defective portion being as a rule sharply defined. The yellow-spot region, as in Mr. Nettleship's case, generally escapes and recovers perfectly from the temporary general blindness. If, however, the general obscuration lasts for long, the yellow spot does not recover perfectly, and central vision is not fully restored. The small arterial twigs which commonly pass outwards directly from the main artery on the disc, to supply the yellow spot, are seldom blocked in the cases under consideration, and it is doubtless in part to this fact that we must attribute the frequent retention of good or even perfect central vision. There are in these cases, as in instances of embolism of the trunk of the arteria centralis, great differences in the ophthalmoscopic changes of the retina, especially in respect to the duration of the retinal haze and the presence or absence of hæmorrhages. Mr. Nettleship thinks that perhaps the chief factor in determining the occurrence of hæmorrhage will be the soundness or otherwise of the retinal capillaries and veins. Something may also be due to the part of the retina involved; thus there would be more probability of passive collateral distension and rupture in the yellow-spot region, where he states that the blood-supply is very free and capillary anastomoses between arterial twigs are found, than in other parts less freely supplied with vessels. Possibly an unusually free communication between the ciliary and retinal arteries near the disc may, as supposed by Knapp, now and then act in the same way. The condition of the *optic disc* is a feature in these cases to which Mr. Nettleship calls attention. In no less than four of seven recorded cases it is particularly noted that the part of the disc which corresponded to the blocked arterial branch was very pale and atrophic, the remainder being either quite healthy or much less pale; while in one of the remaining cases the same is implied, though not quite clearly stated. In his case no difference was noticed between the different parts of the disc, and though a slight variation may have escaped observation, it is unlikely that there was any marked distinction of colour in the parts corresponding to the embolic and pervious arteries respectively. In this connexion Mr. Nettleship observes that in his case all the arteries were at first somewhat diminished, and the whole disc pale, the pervious arteries afterwards regaining about their normal size; the same is noted in one of Knapp's cases, where the pervious arteries were a little smaller than the corresponding branches in the other eye, while the corresponding part of the disc, though less pale than the part belonging to the embolic branches, was still decidedly paler than the disc of the other eye. Mr. Nettleship thinks that the pallor of the disc in cases of embolism must probably be ascribed—first, to an inflammation of the disc, accompanied by the formation of opaque tissue, which may or may not, according to its quantity, interfere with the function of the nerve-fibres passing through it; secondly, to atrophy of the nerve-fibres of the disc, consecutive to atrophy of the retina, the latter being the result of the permanent cessation of blood-supply. If the embolism occludes the trunk of the central artery the whole area of the retina will atrophy, and the consecutive atrophy will include the whole disc; if the embolus shuts off the blood from only a part of the retina, this part alone will atrophy, and the secondary atrophy of the disc will involve only the corresponding portion. That chronic inflammatory changes do occur has been shown by the results of several post-mortem examinations of the optic nerve and disc in cases of embolism, the alterations having been noted especially in the ocular end of the nerve-sheath, and about the lamina cribrosa. That retention of perfect sight by the unaffected part of the retina is compatible with a very definite degree of pallor of the entire disc, also seems to point to the pallor being, in such a case, due to morbid opacity (inflammatory) of the substance of the optic disc, obscuring its capillaries, rather than to atrophy and anæmia. Mr. Nettleship suggests that in embolism of a branch of the central artery, the inflammatory changes may involve either the corresponding part only or the whole of the disc; but the atrophy of nerve-fibres, and consequent intense and punctate whiteness mentioned in some cases, will occur only on the part corresponding to the affected portion of the retina.

---

* Archives of Ophth. and Otol., vol. iii., No. 1, p. 36, 1873.

Mr. Nettleship thus accounts for retention of perfect sight by the unaffected portion of retina, together with pallor of the entire disc, in these cases, by attributing the pallor to newly-formed white tissue, which does not of necessity interfere with the nerve-fibres.

The question may be asked whether in some other cases where good sight co-exists with pale or partly pale discs, the same explanation will suffice? In tobacco amaurosis, for instance, where the patient has recovered almost completely, it is, Mr. Nettleship believes, usual to find the discs in very much the same state as during the amblyopia—viz., exhibiting a varying amount of pallor on the yellow-spot side, the remainder being, as a rule, of healthy colour. He thinks it probable, from the fact that in this malady the failure of sight often precedes by many weeks the appearance of any atrophic change, that the amblyopia is caused by some change occurring primarily in the nerve-fibres themselves, and which impairs their function before causing visible alteration in their structure; rather than by any inflammatory process in the surrounding connective tissue acting secondarily on the nerve-fibres, as in cases of embolism.

CASHEL UNION HOSPITAL.

EMPYEMA; THORACENTESIS.

(Under the care of Mr. THOMAS LAFFAN.)

THE following notes were taken by Mr. O'Dwyer.

J. P——, aged thirty-five, shoemaker, was admitted into hospital on March 21st, 1874. There was a previous history of chronic bronchitis of long standing; his habits also had been intemperate. Pulse 112; respiration 48; temperature 100°. Chest measurements: 18½ in., right; 19½ in., left side.

On admission there were, in addition to the signs of universal bronchitis, signs of effusion occupying the entire of the left half of the chest, as well as of partial effusion in the base of the right pleura. The general condition of the patient was so grave that it was deemed necessary to perform thoracentesis. This was accordingly done on March 24th. The incision was made between the seventh and eighth ribs, and 56 oz. of pus were evacuated by the aspirator. The wound was enlarged, and directions were given to keep it permanently open, but this the unmanageableness of the patient rendered impracticable. The patient seemed much benefited; pulse, respiration, &c., were much improved. On the 27th a bronchial fistula formed, as evidenced by the sudden expectoration of a large quantity of pus and by auscultatory sounds peculiar to that condition. The patient continued in the same improved condition for six or eight weeks. He daily expectorated some pus, and a drain continued also to flow through the small external opening. A tardy consent was wrung from him towards the end of April to have a free opening and counter-opening made. This attempt was defeated by the existence of strong adhesions at the points where the trocar was inserted. Permission to repeat the attempt was sought, but this the patient would not give. He left the hospital on May 3rd, and returned no better on July 3rd. From this time until September his state remained the same. He continued daily to expectorate some pus, but the bulk of what was secreted remained pent up and decomposing in the pleural sac, it being quite clear that the patient was less borne down by hectic than slowly poisoned by the gradual absorption of the decomposing pus.

Repeated efforts were made to obtain his consent to allow free openings to be made in situations where the light of previous experience indicated that they might be made successfully. All these efforts proved in vain; and towards the end of September it became more and more evident that this chronic purulent absorption could have but the one ending. The man remained in the hospital till the end of October. His appetite and strength failed; he became emaciated; his stomach and bowels were both disordered; the local signs and symptoms continued as before; the expectoration was, however, materially lessened; and the pulse and respiration fell nearly to the normal standard. He left the hospital on the 17th October, and died on the 15th November following.

This case seems to teach the necessity for the thorough and continuous drainage of an empyemic cavity. It is also another of those cases which prove at once the safety with which thoracentesis may be performed and the at least temporary gain which it yields. Had the operation not been performed, this man would, in all human probability, have died shortly after his admission. It also shows how imperfect an outlet a bronchial fistula is for purulent secretions.

Reviews and Notices of Books.

Essays and Papers on some Fallacies of Statistics. By HENRY W. RUMSEY, M.D., F.R.S. London: Smith, Elder, and Co.

DURING the past twenty years the name of the author of these essays has been intimately associated with all branches of sanitary reform, and some of his efforts to render State hygiene more of a reality than it has been, or is even yet, will be found in the pages of this volume. A perusal of these essays, some of which were written more than fifteen years ago, is still full of interest from the fact, discouraging as it may appear to an ardent disciple of sanitary reform, that by far the larger proportion of what was then advocated by Dr. Rumsey and others as necessary to sanitary progress still remains unaccomplished. State registration of sickness still exists only in the regions of speculation, discussion, and anticipation. Certification of the causes of death, although somewhat modified and improved by the recent Births and Deaths Registration Act, 1874, is still far from complete, as no provision is yet made for obtaining any trustworthy return as to the cause of death in those cases in which no medical practitioner has been in attendance and no inquest been held. Again, although recent legislation has placed some restriction upon the burial of still-born children, with a view to check the dangerous practice which previously prevailed of getting deceased children interred as still-born, England yet stands almost alone, among nations in which vital statistics are recorded, in the non-registration of still-births.

Notwithstanding these and many other shortcomings, which are ably discussed by Dr. Rumsey in these essays, it would answer no useful purpose to ignore the real progress that has been made in the last few years in the sanitary organisation of the country, which, if it has not taken the form which Dr. Rumsey advocated, has marked the commencement of a new sanitary era. No part of the country is now without its urban or rural sanitary authority, upon which distinctly rests the responsibility of its sanitary condition; and, with few exceptions, each of these authorities has appointed a medical officer of health. Then in the Medical Department of the Local Government Board we have now the hopeful nucleus of a State board of health or Central health authority. The working of the new system has disclosed plenty of defects, and especially the far too permissive character of so large a proportion of recent sanitary enactments; but when combined sanitary districts with efficient and experienced medical officers of health, who are well paid and debarred from private practice, are the rule and not the exception, and the Central authority is invested with an actual power of control, then will sanitary progress become more general, and begin to exercise a more rapid effect upon the public health. The most fatal defect of the present system is that in small towns and in rural districts the sanitary authorities consist in great part of those whose private interests clash with the performance of their sanitary duties. Combined sanitary authorities, in order as far as possible to neutralise these interests, are fully as important in the interest of sanitary progress as combined districts, in order to secure the services of efficient and independent medical officers of health.

But to return to Dr. Rumsey's essays, their subject and scope may be considered from two points of view. First, in their bearing upon the past, present, and future of sanitary organisation and progress, and upon the defects and means for improvement of the various sources of our information as to national vital statistics; and secondly, as to the value of the argument which runs through most of them, depreciatory of what has been styled the *national* system of death-rates, as a test of sanitary condition.

From the first point of view we recommend these essays to the perusal of all sanitarians, as a contribution to the history of sanitary aspirations during the past twenty years, some of which have borne fruit, although not always of the recommended shape, while many of them, as we have noted, still remain mere aspirations. Dr. Rumsey's proposed sanitary organisation, under medical and sanitary superintendent registrars, has, it is true, not come to pass, but most of its objects will be attained under the existing system of sanitary districts, authorities, and medical officers of health, more especially if upon these officers were placed the responsibility of certifying the causes of those deaths in which this information is not attainable either from medical practitioner or coroner. With regard to the defects and shortcomings of our census enumerations, and our birth and death registers, for the purposes of sanitary statistics, it cannot but be useful that they should be generally recognised and understood; at the same time it is desirable that they should not be exaggerated, or their effect overrated. This brings us to the consideration of the second aspect of the volume before us.

The essays and papers here reprinted under the title of "Some Fallacies of Statistics," contain the groundwork and substance of the sweeping charges against the value of death-rates, as published by the Registrar-General, made by Dr. Letheby in his inaugural address in the last session of the Health Officers' Society, an address which was as remarkable for its uncompromising denunciation of the "national" system of mortality statistics as for the fallacious argument by which it was sought to support those charges. Throughout these essays the disturbing influence, among others, of sex and age distribution, is continually dwelt upon, without any attempt being made to ascertain the limit of error that could be thus produced on any existing population. Like many reformers in other fields, Dr. Rumsey has, moreover, been often too intent on pointing out undoubted defects in our sources of information, to appraise at its proper value what has been effected with the aid of this information, or to ascertain what is the actual extent of error which is due to those defects and shortcomings. Hence his conclusions that "the comparison of temporary death-rates for practical objects is a mischievous absurdity"; and that "the indiscriminate appeals so often made to the rates of mortality threaten to become a public nuisance." Such opinions are based on a belief that it is possible for a community in a good sanitary condition to show a high death-rate, and, on the other hand, for a population in an unsatisfactory sanitary condition to show a low death-rate. There is no serious attempt to justify this belief. Although Dr. Rumsey, in a note to one of these essays, states that he does not "attack rates of mortality in the abstract, but only the abuse of them," no impartial reader of the present volume can come to any other conclusion than that he entirely distrusts the "national" system of death-rates. He expresses a belief that under this system a high death-rate may be shown when the correct rate of mortality is really a low one, and that these death-rates are "not only a statistical fiction, but lead to practical mistakes."

Since these papers were originally written and published, the limit of error produced by sex and age distribution in a population has been carefully calculated and proved to be confined within such narrow limits as not seriously to affect the general usefulness of death-rates calculated by the "national" system. The "fallacy" of the birth-rate being the controlling element of the death-rate has been once more exposed, and the oft-urged theory that a high birth-rate produces and explains a high death-rate has again and again been shown to be false; it has also been conclusively proved that, sanitary conditions being equal, the death-rate in populations with high birth-rates should be lower than in those with low birth-rates, because the effect of a large proportion of infants and young children in a population, upon its death-rate, is more than counterbalanced by the inevitably large proportion of young adults, and the small proportion of elderly persons, among whom the death-rate is even higher than among young children. Death-rates, as published by the Registrar-General, in calling into prominent notice the great waste of life in towns, have rather understated the excess of urban mortality, compared with that in rural districts, but all general deductions from them have been fully warranted. The effect of sex distribution in different populations on the death-rate is almost inappreciable, and the individual or aggregate influence of other disturbing causes is insufficient to warrant the surrender of the use of death-rates for general conclusions as to sanitary conditions, more especially as no better test is even proposed. The registration of disease, necessary as it is, and valuable as it will be, will never afford a test of general sanitary condition, as it can only apply to a varying portion of a population.

Although some of Dr. Rumsey's "fallacies" are of his own conjuring and are more or less unsound, and the effect of others is exaggerated, we should advise students of vital statistics, who are now numerous, to read these essays. They are suggestive, even when they are not altogether trustworthy, and after the perusal of what has been written on the other side of the question, the student will be in a position to arrive at independent conclusions on the subject.

Space alone forbids our consideration of many of the interesting and important branches of sanitation which are discussed in these essays, and we can only regret that their influence for good is somewhat affected by the following paradoxical and, as we believe, untenable assertions. Dr. Rumsey says, "a diminution in the rate of mortality will be found to coexist generally with an augmentation of the rate of sickness. The very triumphs of advancing medical art are probably attended by an average prolongation of the helpless and infirm conditions of life." In another place, speaking of the increased duration of life in our great cities as the result of improved sanitary conditions and medical treatment, he adds: "But, at the same time, the sickly and infirm period of existence has been prolonged probably in a greater degree than life itself. Weakly, diseased children are now mercifully helped, as they never were in olden times, to grow up into weakly, ailing adults, who, in their turn, propagate with abnormal fecundity an unsound progeny." Such arguments, if logically worked out, would lead to pure fatalism, and seem out of place when urged by so consistent and ardent a sanitary reformer as Dr. Rumsey. They are, moreover, dangerous weapons to put in the hands of the enemies of sanitary progress, although they might recommend themselves to the Peculiar People.

In conclusion, we may express a hope that Dr. Rumsey's health may ere long allow him again to take an active part in the now more hopeful progress towards a system of public hygiene worthy of being called national.

Outlines of Practical Histology. By WILLIAM RUTHERFORD, M.D., F.R.S.E., Professor of the Institutes of Medicine in the University of Edinburgh, &c. London: J. and A. Churchill. 1875.

THIS handy little book is intended to aid the student in acquiring a practical knowledge of the various means and appliances employed in the investigation of tissues, and it very thoroughly fulfils the object it has in view. During the last few years many improvements have been made in the mode of examining tissues, and chromic acid, gold and silver staining, osmic acid, and the freezing microtome have introduced a new era into histology. The accomplished Professor of Physiology in the University of Edinburgh has had such long experience in teaching that he well knows the student requires to be taught innumerable details in the use of the microscope—the mode of preparing tissues, the use of cutting instruments, and the methods of mounting specimens—which to one more advanced seem almost self-evident. In the very short compass of seventy-two pages this is all admirably done. After a short description of the instruments required, and of the principal solutions needed for hardening and softening tissues, the exact quantities being given, Dr. Rutherford takes a series of objects, in so many brief lessons, by a study of which the young histologist will be conducted through every tissue in the body. This book should be in the hands of every student, and well supplies a want that has been much felt.

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

ON Sept. 17th an association under the above title was formed at the house of S. W. North, Esq., Castlegate, York. There was a considerable gathering of medical officers of health from all parts of Yorkshire, the important districts of the county being well represented.

The meeting took place in reply to an invitation circular issued by Mr. North, who was unanimously voted to the chair. The president informed the meeting that a considerable number of officers of health who were unable to attend had expressed their cordial approval.

Preliminary rules were drawn up, the objects of the Association (as had been well defined by Dr. Parsons) being stated to be, "to promote the progress of sanitary science, to watch the course of legislation on subjects relating to the public health, and to afford mutual counsel and support to medical officers of health."

The following gentlemen were appointed members of Committee, with power subsequently to add to their number:—President: Mr. S. W. North. Members of Committee: Mr. T. Britton, Halifax; Mr. T. Deville, Harrogate; Mr. G. Goldie, Leeds; Mr. E. B. Hicks, Easingwold; Mr. H. F. Parsons, Goole; Mr. W. S. Wade, Wakefield. Hon. Treasurer and Secretary: Mr. J. S. Wesley, Wetherby.

The secretary was empowered to issue circulars to every public health officer in Yorkshire, stating the objects of the Association, and the next meeting of the Association was appointed to be held at the public offices of Dr. Goldie, Corn Exchange, Leeds, on October 27th, at 3 o'clock, members of Committee being requested to attend at 2 o'clock.

MAUNSELL MEMORIAL FUND.

A MEETING of the friends of the late Dr. Toler Maunsell was held last week. The chair was taken by Dr. H. Kennedy, Vice-President of the College of Physicians. There were also present Dr. Stewart, Dr. O'Leary, M.P., Dr. Hayden, Dr. Atthill, Mr. O'Grady, M.B., Dr. Peele, &c. &c.

It was moved by Dr. Stewart, seconded by Dr. Neary, and resolved—"That considering the valuable services rendered by the late Dr. Daniel Toler Thomas Maunsell to the public and the medical profession, by his writings on the Poor-law and the public medical services, and his zealous and untiring efforts to improve the position of the Poor-law medical officers throughout Ireland, his memory is entitled to some substantial mark of public respect."

The following resolution, moved by Dr. O'Leary, M.P., and seconded by Dr. Peele, was adopted—"That a subscription list be opened with a view of raising a Maunsell Memorial Fund. This fund to be applied to the educating and forwarding in life of Dr. Maunsell's family, who at present are insufficiently provided for.

THE LANCET.

LONDON: SATURDAY, OCTOBER 2, 1875.

We deem it desirable this week to consider the general question of specialism and special hospitals, and to endeavour to show wherein either or both may be commendable and wherein they are open to censure, if not to distrust. Specialism, it must be confessed, is to some extent the inevitable consequence of the progress of the science and art of medicine. The rapid strides made during the last fifteen or twenty years in the domains of physiology and pathology, the modern employment of physical modes of examination, the exact methods of diagnosis, the enormous increase in our knowledge of therapeutics, have not only added greatly to the skill of medical men, but have rendered the subdivision of labour more or less necessary, and have led to the institution of special branches of study and practice. If we reflect on the changes that have been wrought in the theory and practice of medicine and surgery by the introduction of the stethoscope, the ophthalmoscope, the laryngoscope, the otoscope, and other mechanical aids to diagnosis, it must be confessed that it is scarcely possible for any one man to excel in the employment of all these apparatus, or to thoroughly comprehend all the multifarious phases of morbid action which the regular and skilful employment of these appliances may disclose. But even this does not justify the existence of such a large number of specialties as we have at present. We do not require, as practitioners of medicine, men who can only use the laryngoscope or the otoscope, nor should we encourage men whose mental vision cannot penetrate deeper than a patient's skin. Surely the average intelligence of man can grasp the knowledge of the ailments of more than a cubic inch of the human body. Everyone, in fact, who engages in the practice of the healing art, and *ipso facto* takes upon himself the responsibility of guarding the health and even the lives of his fellow-creatures, should endeavour to acquire sufficient skill in the use of every apparatus for physical examination as will at least enable him to recognise the presence of disease, even though he should prefer to submit the subsequent management of the case to some one more experienced than himself. But we then produce a specialty. It is the unavoidable multiplication of the departments of practice and the great extension of each department that has led to modern specialism. So far specialism is quite legitimate. Unusual opportunities for observing and studying certain diseases or a certain class of diseases occur to some men, or it may be they purposely devote themselves to the consideration of particular diseases which stand, as it were, by themselves outside ordinary routine practice. It is only natural, when they have thus acquired special skill and knowledge, that they should desire to make them available to others.

This, of course, is not the kind of specialism we object to. The kind of specialism that we condemn is that false specialism practised by those who are either incapable of understanding more than a very small portion of the wide subject of the science and practice of medicine, or seek in the covert and ambiguous paths of specialism a short and easy way to lucrative practice. Not unfrequently they rent a small house in a back street, to which they give the name of hospital for this or that, dubbing themselves chief physician or surgeon according to their fancy, while they procure as members of the committee their needy relatives or some members of the decayed gentry, whose only chance to be known at all consists in having their names printed on the prospectus of the pseudo-hospital. Then follow the impudent appeals to the public—appeals which are not unfrequently downright dishonest, and really made for the purpose of remunerating the medical staff and the committee for services they have never performed, inasmuch as they have had neither patients nor furniture. It is surely time that the public should open its eyes to this serious scandal and refuse to be further imposed upon by the charity swindles. No one charitably disposed should subscribe to an institution the reputation of which is not well known, unless he first take the advice of someone who is acquainted with the hospital system. The Charity Organisation Commissioners are generally in possession of useful information respecting the metropolitan hospitals, especially the shaky ones; and from the report of the Hospital Sunday Fund Distribution Committee a very good estimate may be formed of the merits of particular institutions.

Finally, to come nearer home, we would warn students—whether they are entering on their medical career now for the first time, or have already completed part of their curriculum — to regard special hospitals with a jealous eye. Students, especially the senior ones, with a mistaken zeal for knowledge, are, we fear, too apt to neglect their own tried teachers and to run to special hospitals, in the vain belief that they are adding greatly to their store of experience by listening to the oracular utterances of the presumptuous and self-elected instructors who preside at these places; whereas, if they saw things in their true light, they would find that their new love was, in ninety-nine cases out of a hundred, immeasurably inferior to the more modest but better-educated teachers attached to the tutorial hospitals.

◆

The ninth series of half-yearly Reports supplied by the surgeons to the Customs at the Treaty ports of China have just been published, and contain much information of considerable interest to the profession generally, as well as to those who, by connexion with the locality, are more immediately concerned. These Reports originated, our readers may remember, with the Inspector-General of Customs at Peking, who thought it well to take advantage of the peculiar opportunities which the surgeons at the Custom ports of China possess of gaining accurate information concerning the medical circumstances of the inhabitants of the country and of the locality. The series just issued comprehend Reports on Kiukiang, Shanghai, Peking, and Foochow, by the surgeons stationed at the respective ports, arranged for publication by Dr. Jamieson, of Shanghai.

The individual Reports vary in the information they contain according to the medical opportunities which the stations respectively present. At Foochow Dr. SOMERVILLE has nothing but meteorological observations to record; while the accounts from Shanghai and Peking are of very considerable medical interest; their authors, Drs. JAMIESON and DUDGEON, deserve great credit for them.

Among the prevalent zymotic diseases small-pox takes the most conspicuous position. It has existed as a severe epidemic throughout the east of Asia, and is still now frequent in China and in India. To what extent vaccination is employed does not appear, but it is receiving the countenance of persons in high position, the little Emperor having been vaccinated, as well as the Emperor and Empress of Japan. Whooping-cough is prevalent among foreign children at Peking. The increase in diseases connected with insanitary conditions, such as typhoid fever and erysipelas, at Shanghai, is very suggestive of evils which must be hard to remedy where the means necessary are so foreign to the habits and customs of the people. Among curious facts mentioned with regard to the Chinese is the prevalence among them of hæmoptysis. Hæmorrhage from the lungs is both frequent and severe, but there seems to be an immunity from what are here its usual consequences. Persons are often subject to the disease for years, following some of the roughest and most exposed occupations, without evidences of further lung mischief. It is worth inquiry whether there may not be here some unusual condition of the lung causing the hæmoptysis, such as miliary aneurisms. Aneurism of large vessels and heart disease—in Peking at least—are very rare.

A curious association of boils with malarial poisoning is mentioned by Dr. JARDINE. Simultaneous attacks of intermittent fever and of boils among members of the same family in the same household were met with. "On one or two occasions neuralgia preceded the outbreak of the boils, and many had an attack of fever ushering them in. If there was a recurrence of the paroxysm of fever no boils appeared, and when boils presented themselves there was an end to the fever." It is said that in certain malarious districts of America an attack of boils is considered a safeguard against an attack of intermittent fever. In all Dr. JARDINE's cases quinine was found beneficial, not only in hastening suppuration, but in preventing a recurrence of the attack.

Perhaps the most interesting portions of these Reports are those in which incidentally descriptions are given of various points in the native pathology and practice. The systematic elaborateness which is so characteristic of Chinese theory shows itself conspicuously in their descriptions of disease. The accounts of disease which are given in the native medical books are very full; the supposed causes, symptoms, and varieties being described with great minuteness and refinement. They recognise many varieties of disease, founding them on principles not altogether different from our own, depending especially on the supposed causes, characteristic features, or imagined relation to viscera. They apply the same form of classification to many diseases, and are specially fond of adopting the division founded on the five senses, or on the five viscera which they enumerate—the lungs, heart, liver, stomach and spleen, and the kidneys, according as the stress of the disease seems to have fallen on one or the other of these. They enumerate, for instance, five different forms of small-pox corresponding to these five viscera. The medical works are most voluminous. It is the custom to state whatever any previous writer has said on the subject, and, in addition, to give the views of the writer himself, no attempt being made to point out the errors of preceding writers or to sift the true from the false.

Walnuts are ordered in disease of the testes; the Siberian crab in ulcer of the breasts. The latter may suggest a curious association with cancer of the breast; but cancer is not recognised as distinct from ordinary ulcers, and the Chinese can with difficulty be prevailed upon to submit to any special treatment for it. In accordance with the same principle we find that a favourite remedy for impotence is the penis of certain animals, that of the dog, ass, or deer being preferred on account of their respective qualities of hardness, length, and strength! The testicles of the deer are also taken for the same purpose. In the list of remedies for every disease we have an equally absurd series of agents, some selected on the same principle, others having no apparent association with the disease to be cured. For instance, fifty different remedies are enumerated as accelerating, and an equal number as easing, parturition. None of the former, except perhaps camphor and iron, have any western reputation for the purpose. The list includes the most fanciful and disgusting compounds. The comb of a black cock and a husband's garters are among the least repulsive. The Chinese doses are always large. The habit, consequently, acquired of swallowing large quantities of the medicines prescribed renders it dangerous to entrust them with any considerable quantity of a powerful drug, and has been found a troublesome characteristic in dispensary practice. Arsenic, for instance, cannot be used for ague on this account. The Chinese doctors rarely prescribe powerful foreign remedies on account of the uneasiness their potency excites. Indian hemp is one of the agents of which the Chinese physicians are afraid; and yet it affords a striking illustration of the manner in which, as we have said, some of our important methods of treatment were anticipated long ago in China. It is supposed, Dr. DUDGEON informs us, to have been the substance used by a celebrated surgeon, HWATO, who flourished A.D. 220–230. "It is mentioned in the 'Collection of Ancient and Modern Medicine'—a book published in the beginning of the 16th century,—that, in acupuncture and in applying the moxa, HWATO gave a preparation of hemp, which in a short time produced such anæsthesia as if the patient had been either drunk or dead. During this period of loss of sensation, openings, cuts, amputations, &c., were performed without the slightest pain being felt." Fumigation is the common method of treating asthma in China. Curiously enough, one prescription for a compound to be smoked contains an ingredient which is said by many botanical authorities to be stramonium itself. It is a drug introduced from abroad. It is remarked how many foreign substances have found their way into the Chinese herbal. Some were introduced from India by the Buddhists and others, and have retained their foreign names, at least to such an extent as to admit of their identification.

Another remarkable fact is that the Chinese treatment of syphilis for the last 2000 years corresponds very nearly with our modern therapeutics. "Calomel, cinnabar, and realgar are among the recognised formulæ, and the calomel enters into every prescription." Prescriptions are also given to drive out the poison of calomel after it has effected a cure; and for this is used a kind of sarsaparilla, which is prescribed with an aperient. Moreover, we have been anticipated even in the method of employing mercury in syphilis. Fumigations and vapour mercurial baths, both local and general, are employed by them. One prescription for the purpose contains lead and mercury, cinnabar, olibanum, myrrh, dragon's blood, realgar, and aloes-wood, the whole to be pulverised, wrapped up in paper to form a wick, and put into a lamp. The patient is to be covered over, and inhale through the nose, taking cold water into the mouth to preserve the teeth. Secondary and tertiary symptoms are regarded as not so much a further development of the disease as of the calomel—a notion also not confined to the Celestial Empire. Foreign medical men have much surgical practice. That branch is somewhat lightly esteemed by the native practitioners, who have more faith in their skill for the cure of internal diseases which are hidden, and hence beyond the scrutiny of the patient. Native surgery consists chiefly of acupuncture, the moxa, and plasters, and is relegated to druggists, street quacks, and Mongols. It is satisfactory to learn that the Chinese seldom blame the profession for any untoward course their diseases may take. Death is ascribed to fate, and any unfavourable symptoms are accounted for on the supposition that they have caught cold. The life of many an English practitioner would be relieved of much needless worry were his patients equally philosophical!

◆

WE commend to the careful study of our readers the lecture "On Softening of the Brain," by Dr. J. HUGHLINGS JACKSON, which we published on the 4th of September. It contains very much that is suggestive on this subject, not only in the region of diagnosis and pathology, but also in that of therapeutics. The precision of thought and language, the strict adherence to what is justified by clinical and pathological observation, which form always such a valuable part of Dr. JACKSON's treatment of a question, are very noticeable in this communication. And the subject is one which is of immense importance in practice. There is a great deal of talk nowadays, even in common parlance, of softening of the brain. Happily, we can say now, on Dr. JACKSON's authority, there is a great deal too much talk. That is to say, people, even educated people, talk about softening of the brain where it does not exist. The cases thus wrongly called softening of the brain are really cases of nervous exhaustion, to be remedied by simple common-sense care. Supposing a man to have exhausted his system by excess of any kind—excess of work, by sexual excesses, by various excessive excitements,—and to display in more or less perfection the group of symptoms described by Dr. JACKSON—irritability, despondency, slight power of attention, feeling of pressure or burning at the back of the head, a "queer," "intolerable" feeling at the upper part of the spine, often intermittent;—supposing a man to have these feelings and no others, Dr. JACKSON believes that they are to be removed by "common-sense care"—that is to say, by proper regulation of work and passion and habit.

The great point which Dr. JACKSON insists on is that softening of the brain is essentially a localised disease, never affecting the general body of a hemisphere, but a more or less limited spot, answering to a certain arterial supply; secondly, that it means bad *arteries*—that is to say' arteries blocked either by embolism or by thrombosis, more frequently the latter; and, thirdly, that the symptoms of such a real lesion as this are very real, though negative, consisting of loss of faculty—such as loss of speech, loss of power over one side. Though there are cases of temporary loss of speech and hemiplegia which do not admit of this explanation, and indeed are still very inexplicable, all those who have watched the progress of recent pathology will agree with Dr. JACKSON, and thank him for giving out the truth with so much plainness—that the reason why the highest part of the motor tract (corpus striatum) and adjacent convolutions are usually the parts to suffer damage—softening—is simply a mechanical one: viz., that they are supplied by the middle cerebral artery, which often gets blocked up. Being in the direct line of the circulation, this artery is most liable to receive a fibrinous plug from the heart, or by the strain of the circulation to have degenerative changes set up in it leading to diminution of its calibre and blocking. There may be general mental symptoms preceding and following this grave and very defined interruption of a given arterial supply; but the direct effect and proof of it is to be found in such symptoms as hemiplegia, or loss of speech, without loss of consciousness. An important part of Dr. JACKSON's lecture is that in which he discusses the significance of what he calls general mental symptoms positive and active, as distinguished from special mental symptoms of a negative character; the more so as he shows that decided therapeutical courses depend on the intelligence with which we discern this significance. Dr. JACKSON calls the grave symptoms, really indicative of serious brain disease, *physical*—such as gross motor affections, convulsions, and paralysis,—in contradistinction to what he would call the *mental* symptoms—illusions, delusions, grotesque actions implying an *over-excitement* of the lower nervous arrangements *permitted* by the loss of control of the higher nervous arrangements.

Good practitioners will not fail to receive the caution which Dr. JACKSON gives as to depleting patients suffering from sudden loss of speech or from hemiplegia, on account of symptoms falsely supposed to indicate inflammation of brain membrane or tissue, but which are really due, some of them to the mere excitement of the attack, and others to the debility and anæmia of the brain resulting from the sudden stoppage of food supplies. It is to be feared that too many still treat a brain suddenly failing as if it were strong and over-nourished, instead of remembering that the very occurrence of loss of faculty is a proof of such a state of vessels as involves impoverishment and starvation of brain-tissue. Dr. JACKSON says "we should be cautious how we begin to change a man's habits, even bad habits, very soon after an attack of hemiplegia." Of course Dr. JACKSON would not wish us to overload the stomach with food or to charge the blood with alcohol. If we rightly apprehend his meaning, it is to the effect that no sudden changes in diet should be made which will have the effect of lowering the arterial tension and the supply of pabulum to the parts of the brain geographically furthest from the heart.

There are two points in Dr. Jackson's lecture of the highest interest upon which we should desire to hear more fully from him. The first is the opinion which he expresses that we shall find the explanation of the neuroses proper, such as chorea and epilepsy, in the condition of the arteries: "*My own belief is that in this direction of inquiry we shall find out the pathology of the neuroses. I do not believe that chorea and epilepsy are nervous diseases in the sense that the pathological changes* BEGIN *in the nervous tissue.*" Considering our ignorance of the pathology of these diseases—that they occur at periods of life when degeneration of arteries does not exist—that their whole character, history, and causation differ so much from those of softening, hæmorrhage, &c.,—this seems to us a very bold opinion. But Dr. Jackson is not given to speak without data, and we look confidently for some justification of his opinion.

The other point is that, allowing the dependence of such diseases as softening, hæmorrhage, &c., on arterial changes to be, as Dr. Jackson says, affairs of arteries, the question of heredity yet remains. It may still be true that arterial degeneration in some families will take the shape of diseases of the nervous system more than in other families. It nevertheless is of vital importance to realise the truth that the causes of paralysis are primarily in arteries, and not in the nervous tissue itself. We seem to know something of, and have some control over, the causes of arterial degeneration; and perhaps the best way in which we can preserve the integrity of arteries is by cultivating such habits as tend to preserve the integrity of the great eliminating glands, such as the kidneys and the liver.

Annotations.

"Ne quid nimis."

THE INTRODUCTORIES.

The 1st of October, and with it the commencement of the academical year, has again come round, and teachers and students with their friends have again exchanged their greetings and listened together to the time-honoured "introductories." Nor have these been wanting in the diversity which has been their most distinctive feature of late years, which seems to render it necessary for each one who delivers such an address to define what in his opinion is the object and scope of an introductory, and to enter upon a defence of his own particular view. It is not our purpose now to discuss the origin and utility of introductory addresses in general, especially as we have often had occasion to expound our views upon the subject. We believe that they may be made extremely useful, if rightly directed; and we should much regret to see the example of the one hospital which has given them up generally followed. To the student who is freshly entering on his medical studies the "introductory" is a momentous affair; to his uninitiated mind it is a mysterious ceremony, at which he will first, with bodily vision, see those distinguished men by whom he is to be trained and taught, and whose names he has already learned to reverence. He anticipates, moreover, that he will receive some direction as to the conduct of his future work, or that the veil will be lifted to give him a glimpse of the mysterious land of knowledge which lies before him, and of which he is as yet profoundly ignorant. To the more advanced student it is a return to work in which he has already made advances, but where there are ever new fields of interest opening up in which he needs not only instruction but guidance and example to enable him to overcome the difficulties which beset him. And to him, as well as to the teacher and practitioner, the opening address is a fresh trumpet-call to the onward march in the noble work of advancing science and curing disease. Such, we trust, will be the effect of the addresses this year; their results will, we hope, be seen in the character of the work of the session now commencing.

VACCINATION.

The Appendix to Mr. Simon's last Annual Report on Public Health (to which special reference was made in The Lancet of last week) is mainly occupied by a most valuable report on vaccination and small-pox, compiled by Dr. Seaton, assistant medical officer to the Local Government Board. It includes the first annual return under the Vaccination Act 1871, and has reference to the children born in England and Wales in 1872. It appears that of 821,850 births returned to the Board by the several vaccination officers in the kingdom as registered during that year, 698,137 (or 85 per cent. of the whole) had been registered as successfully vaccinated at the time the return was made; 1693 (or 0·2 per cent. of the whole) had been registered as unsuccessful (after having been, of course, unsuccessfully vaccinated three times); 905 (or 0·11 per cent. of the whole) as having contracted small-pox before they could be vaccinated; and 78,594 (or 9·5 per cent.) as having died before they could be vaccinated; leaving 42,527 (or 5·1 per cent. of the births) still to account for. If from the 821,856 births deduction of the deaths without vaccination be first made, it appears that of the surviving 743,262 children about 94 per cent. were returned as successfully vaccinated, 0·35 per cent. as either insusceptible of vaccination or having had small-pox, and 5·72 per cent. as still to account for. A further analysis shows that the cases not finally accounted for consist of those in which vaccination was at the time of the return postponed on account of the child's health, or cases removed from the district or place of birth before vaccination, or in which the operation, though performed successfully, could not be registered as such, because the legal certificate had not been received by the vaccination officer. The number of direct refusals on the part of parents to have the operation performed constitutes an utterly insignificant proportion of the cases unaccounted for.

Having regard to the fact that this was the first year's working of the Act, that 1400 local officers were employed acting under the direction of 647 boards of guardians, and that the duties devolving on these officers were new, it must be acknowledged that the results are very satisfactory.

An examination of the cases not finally accounted for, shows that the proportion in the metropolis considerably exceeds the average of the rest of the United Kingdom, due probably to the large number of lodgers, and also to frequent removals.

A total of 275 unions were inspected last year, with reference to their proceedings under the Vaccination Acts of 1867 and 1871, and the sums awarded to public vaccinators for successful work amounted altogether to £8204. There are 23 vaccinating stations in England, 1 in Edinburgh, and 2 in Glasgow; and of these the Surrey Chapel, Tottenham Court Chapel, Pimlico, Westminster, Marylebone, Whitechapel, and Strand establishments are also vaccination stations, as well as those at Manchester, Birmingham, Bristol, Liverpool, Newcastle-on-Tyne, Leeds, Glasgow, Edinburgh, Exeter, and Sheffield. During the year 12,963 charged ivory points and 30,045 charged tubes (each estimated as equal to 10 ivory points) were supplied from the stations, 10,478 applications for them having been made—viz., 9320 from practitioners in England and Wales, 4 in Ireland, and 237 in Scotland, 533 from the Army, 76 from the Navy and Emigration Department, 206 from the colonies, and 102 from the diplomatic and other foreign sources.

SICK NURSES AND THEIR COSTUMES.

There is a popular saying that no one can be "a good nurse without being a born nurse," and there is just that amount of truth in the expression which everyone can appreciate. It would be more correct to say, however, that some persons would never become good nurses with any amount of teaching; they lack the temper, tact, gentleness, fortitude, and intelligent appreciativeness necessary to make a nurse. But, good, bad, or indifferent, rich or poor, it falls to the lot of most women at some time or other of their lives to have to discharge the duties of an amateur nurse to a sick child or relative, and there is a right and a wrong way in this as in everything else worth doing. To begin with, most people, and especially sick people, would prefer to have a fresh, comely, and cheerful attendant to a bilious-complexioned, funereal-looking old "frump." And this reminds us that there is much room for improvement in the matter of the personal attire of nurses. It is common enough for a medical man to be called to a case of grave illness in some household where the patient is being nursed, and often very badly nursed too, by some one or more near relatives, who are already worn out with watching. The first thing to be done is to secure the services of some trained nurse, and if she turns out a good one, as is usually the case—for the Gamp variety is happily as extinct now as the dodo,—the benefit of her presence in the household is little short of a blessing to everyone. But there are the scruples of relations to be overcome; they have an affectionate solicitude for the patient which a stranger cannot feel, and they often seem to regard the presence of a professional nurse as an abiding gloom, instead of welcoming it as a great relief from worry and watching. This is to some extent to be attributed, we think, to the feeling associated with a nurse's costume. While so many ladies and others, who are unselfish and devoted in the discharge of their duties as nurses, are not content with doing good for its own sake and for its own reward, but must conform to some system, and attach themselves to this or that ecclesiastical or religious society, we must expect that there will be uniformity in the matter of their attire, indicative of the order to which they belong rather than of the duties they have to perform. At the good that is done we rejoice, but we think that the usefulness of such people is often much restricted in this way. The sick poor, for example, speedily discriminate the difference between sympathy and services rendered primarily and exclusively to and for themselves, or only to them as a means to another end. Moreover, sick people are every bit as fastidious in their tastes as healthy people, and whilst we attend to the æsthetics of a sick room by flowers and other pleasant objects, why should nurses be so often attired as if for a funeral, in black and white? There is no more excuse for a nurse making a "guy" of herself than for her being decked out in vulgar finery, with her hair got up after an elaborate style which it would take her half the day to arrange. Print dresses of pretty pattern, or grey alpacas, according to season, with a light white cap, linen cuffs and collars, scrupulously white and clean, and a coloured neck ribbon, would, it seems to us, be infinitely preferable to the black costumes of the sisterhoods.

THE FACTORY POPULATION.

Some few weeks ago we took occasion to draw the attention of our readers to a report by Dr. Ferguson, at Bolton, which referred very distinctly and emphatically to the progressive degeneracy of the factory population. Mr. Redgrave, senior inspector of factories, in his last official report, demurs to the conclusion and the evidence upon which it is founded. He says: "Before we can accept as proved the statement that the factory population is degenerating, a very clear and detailed publication of facts, gathered not in one town only, but in fifty towns, must be presented to us." The inspector then, speaking as a layman, avers that since 1848 there has been a material improvement in the physical condition of the English operatives, and that although the factory hands in some of our densely-populated towns may not compare favourably with those who worked in what were some time ago country districts, the workers in the smaller textile towns and villages of Lancashire and Yorkshire are as well-grown, as well-developed, and as healthy as the working classes in any county in the kingdom. Mr. Redgrave doubts also whether there is either an increase of immoral habits or in the consumption of alcoholic drinks. "The breaking-down of the health, the curved spine, the deformity of the extremities, are not now to be met with," but there is an increased and increasing employment of women in factories. The official returns in 1848 gave an average of eighty females above thirteen years of age employed in the Lancashire cotton factories, whereas one hundred is the average at the present time. Evidence has been given frequently of the disastrous consequences to child-life and infant development by the working of the mothers in factories. "The abstention from factory labour of women for a month or six weeks after confinement would to a small extent mitigate the evil as regards their more certain retention of health, but it would not touch the evils of the loss to the infant of its natural food and of maternal care and love while abandoned to the indifference of a sordid nurse and the baneful influence of a soothing cordial." There can be no doubt that the evil thus described by Mr. Redgrave demands serious attention, and our legislators should endeavour to protect the health of the mother and the well-being and physical development of the offspring.

BOGUS DEGREES.

Can nothing be done by Congress to regulate the system by which medical diplomas and degrees are granted in the United States? We gather from our own correspondence with members of the profession in America that they sincerely desire that more strictness should be exercised in the legal recognition of practitioners. Not long ago we were asked for information as to the working of our own Medical Act by practitioners who were desirous to see it applied in the States. The letter which we published last week from his Excellency the Acting Commissioner of the Bureau of Education, Washington, to Mr. Sparkes, of Shelton, Stoke-on-Trent—part of a correspondence which has been kindly forwarded to us—shows that the American Government is not uninformed as to the existence of "fraudulent" institutions in the States which supply "handsome diplomas and certificates of registration" for money considerations only. It is gratifying to have the assurance of the Acting Commissioner that one such institution has had its charter withdrawn, and that it has no "actual or legal existence." But the evidence is still considerable that something representing it still exists, and is not alone, to supply degrees to those who have more money than self-respect. Mr. Sturman, of Packington-street, N., in his letter published last week by us, says, "I can influence you (*sic*) the diploma A.M. and Ph.D., B.Sc., or D.Sc., &c., *from several universities in the States.*" Dr. P. F. A. Van der Vyver, of Jersey, makes a similar offer to Mr. Sparkes in the course of the correspondence above referred to and now before us. It is not enough for the satisfaction of public opinion, either in the States or in England — for England is greatly interested in the condition of the medical profession in the United States—to be told by the Commissioner that no respectable institution in the United States confers degrees for money. What we want to know is, not only the number of institutions covered by Mr. Sturman's expression, "several universities in the States" which sell degrees, but also the number of universities, colleges, or medical societies in the States that have the serious power of granting degrees or diplomas, and, further, the extent to which they are supervised by any body answering to our own Medical Council. We know too well, even with a body specially created by Parliament to superintend our nineteen examining bodies, how possible it is for unfit men to enter the profession. We know how much worse it is and must be in the States, where every State is a law to itself in this matter, and recognises anything that looks like a diploma. We have reason to believe that Congress, at its next meeting, will be asked to pass a law in the direction of our own Medical Act. We devoutly hope it will accede to this request. We do not write in the interest of any medical theories. We only want, for the sake of human life and progress, that men practising the calling of medicine in the States shall give evidence of their knowledge of anatomy, physiology, and of the means by which disease may be detected and treated. We know that there are schools of medicine in the States not to be well excelled in Europe, but Congress owes it to these schools and to its own citizens to, if it can do so, withdraw all legal recognition from the multiplied societies which can show no adequate means for educating and examining students, and give no adequate excuse for their own existence as licensing bodies.

THE CONTAGIOUS DISEASES ACTS.

AT the recent International Medical Congress at Brussels an interesting and useful discussion was provoked by a communication from Dr. Chapman, in which it was attempted to be proved that the surveillance of prostitution is to be condemned because it leads to clandestine immorality. Dr. Sigmund, of Vienna, on the other hand, stated that since a system of surveillance had been adopted there a remarkable diminution had taken place in diseases of this character, both as to the number of cases and their virulence. Dr. Vleminckx, the President of the Congress, declared that the mastery over the scourge in Belgium had been obtained only by a system of legal surveillance, adding, at the same time, that he was unable to understand why England, which decreed obligatory vaccination, does not take a like action in this matter; the maintenance in England of the English way of treating this grave question appeared to him a danger for the whole of Europe. This is the view, we are glad to see, held by nearly all continental physicians, and others having a really practical knowledge of the subject, as opposed to those, whether in this country or abroad, whose conclusions are derived from theoretical considerations, or greatly influenced, if not based, upon sentimental ones. In the face of the evils which confront us in daily life, and in opposition to the logic of facts, it certainly seems strange that attempts to limit the spread of one of the direst maladies in the world in a reasonable and common sense way—in the only way, be it understood, that any attempt can be made from its physical side—should have excited so much opposition. It is to be accounted for, however, by remembering the sources from which such opposition has sprung. It has not sprung up in districts where the Acts have been in force, and among people acquainted with the facts, and who have had experience of the beneficial working of these Acts, but in towns and places where the inhabitants have not been able to see for themselves the favourable contrast which a town presents in this respect after such legislation has been extended to it to what it did before. However, we think that we perceive signs of the waning influence of excited oppositionists. There is nothing like a vigorous discussion of the subject in the House of Commons, and a rigid scrutiny of the assertions and arguments of those most violently opposed to these Acts, for demonstrating the inaccurate and fallacious character of what has been advanced against them. Instead of declaiming against the existence of the present laws, it would be wiser to inquire whether the measures adopted for the prevention of contagious disease were not still insufficient.

ARTIFICIAL RESPIRATION.

SOME nine years ago Professor Schiff, of Florence, in his lectures on the nervous system, announced that in fulminant apoplexy consequent on paralysis of the medulla oblongata artificial respiration—never bleeding—was the treatment indicated. This induction he had reached after numerous experiments on the lower animals. By artificial respiration the blood is saturated with the oxygen, indispensable to life, while the pressure of the circulation is kept low, so as to obviate a new hæmorrhage in the brain. For this reason, to say nothing of the fact that the artificial introduction of air can be regulated according to the requirements of the case, Prof. Schiff prefers the artificial respiration by means of the bellows to the respiration of pure oxygen.

His assistant, Dr. Corso, describes a case in which the efficacy of the practice was well illustrated. A lady having accidentally fallen on her occiput was brought into hospital with fracture of the base of the skull. Immediately on admittance she was found insensible, with her eyes closed, her face cyanotic, the respiration very slow and shallow, pulse small and feeble, and, in fact, all but moribund. Artificial respiration was at once practised. After a few minutes the heart began to beat with greater frequency and force; in twenty minutes' time natural respiration was re-established, and sensibility returned. Next day she had improved to such a degree that she could sit up in bed and eat by herself. The intellect, however, was not perfectly restored, her attempts at discourse being incoherent. This indication of lesion of the cerebral substance increased, till after fifteen days she died. At the autopsy there were found fracture of the base of the cranium, hæmorrhage on the right side extending down to the medulla oblongata, and lesion of the substance of the brain.

The immediate danger in apoplexy lies in paralysis of the medulla oblongata, and consequent impairment of the mechanism of respiration. If this patient had not had, together with the hæmorrhage, lesion of the brain, which is common to apoplexy, whether spontaneous or produced by an external cause, she would (says Dr. Corso) have been saved. By artificial respiration time is given to the brain and medulla oblongata to recover the shock and resume their functions, if not perfectly all at once, still in such degree as to maintain life and make improvement possible.

Even as it was, the patient, but for artificial respiration, must have died within a few minutes after entering the hospital. A great future, thinks Dr. Corso, lies in store for artificial respiration; pulmonary diseases, in particular, seem a fertile field for the practice.

THE POLICE TREATMENT OF DELIRIUM TREMENS.

We have hitherto supposed delirium tremens to be a disease, doubtless a most improper one to contract, and the circumstance of suffering from which must needs go far, though not always conclusively, to imply a dissipated habit and demoralised character. It now appears that the malady is included in the category of those affections for which the police are considered the best physicians, and to which they apply the universal specific of Scotland-yard—brute force and a *régime* dictated by economy, and the propensity for doing as little as possible, and that little ill. "A fine-looking man, who was evidently suffering acutely from a severe attack of delirium tremens" (we are quoting from one of the daily papers) "was charged (at the Thames Police-court) with attempting self-destruction." The report goes on to describe how the accused was so excited that constables were compelled to stand by him in the dock, and it concludes by informing the public that, after his forcible removal to the cells, his yells were heard, "but they gradually subsided as if he had exhausted himself." He was remanded to the House of Detention for a week. Not a word was said about subjecting the poor creature to medical treatment. Possibly the magistrate may have considered it likely the prison authorities would call in the services of their medical officer, but he did not allude to such a contingency, or suggest that the procedure would be prudent. In short, the magistrate handed over the treatment to the police as unreservedly as if the case were only one of fractured skull described in the charge-sheet as "drunk and incapable." It is difficult to accept this view of the matter as satisfactory. We have no desire to qualify the feeling of righteous indignation which even a stipendiary justice of the peace must feel when he encounters a person suffering from delirium tremens *presumably* brought on by excessive drinking. We do not even wish him to temper justice to the crime of excess with mercy for the victim of a self-induced disease. But we cannot help thinking it will be well to follow the old-fashioned practice of treating all maladies as calling for medical care, without regard to the manner in which they may have been contracted, and punishing the offence *after* proper measures have been taken to cure the offender.

SEA-BATHING.

Although the larger proportion of sea-bathers have, probably, abandoned their healthful exercise, many are asking themselves whether it is prudent to continue the pastime now that the year has entered its autumnal phase, the temperature is generally depressed, and the weather uncertain. Wind, rain, and cold are disagreeable attendants on the open-air bath, and detract seriously from its comfort, if not from its usefulness, to all except the most robust. The expediency of facing the occasional inclemency of this variable season should, for invalids and delicate persons, be a question to be decided by their medical adviser. It is a matter of considerable moment, and one which cannot safely be settled offhand, from the apparent condition of health and weather. Bathing too late in the season is to many persons a cause of cold and rheumatism, possibly even of worse misfortunes, which may last far into the winter. The evil effects of the hazardous experiment may not be immediately perceptible. The vital heat is lowered by the repetition of cold baths, from the "chill" of which the organism never perfectly recovers. The average temperature, or heat-force, is after each bath left a little lower than before. The reaction is not sufficiently prompt or strong to re-establish the normal condition. Sometimes—and perhaps this is the worst event, because the phenomena are deceptive—there is every appearance of reaction. The surface becomes flushed after leaving the water, the heat seems to be restored, and the sensations are agreeable. But the reaction is not natural. The accession of apparent warmth is in fact a slight pyrexia. It comes on too quickly. It is either distinctly febrile, accompanied by acceleration of the pulse and almost hectic flushing, or it passes immediately into a sweating stage, in which the temperature is rapidly depressed and the vital strength exhausted. Medical practitioners will do wisely to inquire somewhat more closely than may at first sight seem necessary into the symptoms exhibited by clients—we mean persons in generally good health—who consult them as to the wisdom of continuing the bath at this critical period. It is just the time when to swimmers and bold bathers the attractions of sea-bathing are especially seductive, but the atmospheric conditions call for unusual care.

THE MORMONS AND POLYGAMY.

The Report on the Hygiene of the United States Army, with descriptions of the military posts, being No. 8 of the magnificent series of publications issued from the Surgeon-General's office, War Department, Washington, contains a description of Camp Douglas, Utah territory, with some interesting observations by Surgeon E. P. Vollum, of the United States army, on some of the diseases of Utah. The adult population of the Salt Lake Valley are as robust as any within the borders of the United States, and there is a fair number of cases of extreme old age. The weight of sickness falls upon the children, who furnish not less than two-thirds of all the deaths, most of which occur under five years of age. The figures of the register show that the male deaths exceed the female by about 50 per cent. Surgeon Vollum adds that the polygamous children are as healthy as the monogamous, and the proportion of deaths about the same; the difference is rather in favour of the former, who were generally, in the city especially, situated more comfortably as to residence, food, air, and clothing, their parents being better off than those in monogamy. It is, perhaps, too early to express any mature opinion as to the influence of polygamy, as contrasted with monogamy, on the health or constitutional or mental character of the Anglo-Saxon race as seen at Utah; but the reporter states that, as far as his experience has gone, no difference can be detected in favour of one or the other. Polygamy in Utah, as far as Surgeon Vollum can learn, furnishes no idiocy, insanity, rickets, tubercles, struma, or debasing constitutional condition of any kind. The great mortality in the children is confined chiefly to the Mormon population, and it may be traced to absence of medical aid, nursing, proper food for sick children, and neglect of all kinds. Among the many mottoes that decorated the Tabernacle on the last anniversary of the advent of the Mormons into Utah, was "Utah's best crop: children." Abundance, says Surgeon Vollum, doubtless cheapens the value of anything, children as well, especially when the issue of several women are begotten in poverty, and all mingled together and contending like birds in a nest for the morsels within reach. The children of Salt Lake city may often be seen in groups insufficiently clad, the lower half of the body bare, playing about in the cold water that flows directly from the mountains and down each side of the streets. The consequence is catarrhs, pneumonias, fevers, and bowel complaints. The nonsensical mummery of "laying on of hands" is taught and practised by the priesthood, and the faithful and the ignorant resort to it with confidence for the cure of disease. Some observers imagine they notice a saddened expression of countenance on the Mormon children—that they have not the cheeriness and laughter common to that age; especially that the young women, who here are robust, ruddy, and well made, lack the amiable, bright, and cordial countenance characteristic of young women everywhere; and they attribute this supposed dulness of face to the pre-natal influences of the polygamous relation on the mothers. "Certainly," adds Dr. Vollum, "I have thought at times that there was some truth in the notion."

COEXISTENCE OF LUPUS AND CARCINOMA.

THE interesting fact of the occasional supervention of cancer upon lupus has received fresh confirmation at the hands of Professor E. Lang, of Innspruck (*Vierteljahr. für Dermatol. u. Syph.*, 1874, p. 165), who records a well-marked instance. He believes that many cases previously recorded were simply examples of the extension of the original lupoid affection, which would render the number of cases in which the combination occurs very limited. Of these cases two divisions may be made—viz., those in which the cancer springs up on the site of lupoid scars, as it frequently does on simple scars, and those in which both the cancer and lupus extend *pari passu.* The case which forms the subject of his paper was one of the latter group. The patient was a young man twenty-five years of age, admitted into Professor Heine's clinic at Innspruck in March, 1873, who had been the subject of lupus from the age of about three years, the disease commencing on the right side of the face and the left arm, gradually extending to the forehead, left side of face, and forearm. When admitted the face was almost entirely converted into a smooth, hard, somewhat reddened cicatrix, here and there covered by layers of exfoliating epidermis, and bordered by well-marked lupus nodules. The right lower eyelid was everted and the right cornea opaque; the cartilaginous part of the nose was absent. Between the upper lip and right lower eyelid was an ulcer the size of a finger-nail, with sharp undermined edges and irregular base. This ulcer had commenced in the previous autumn, and was accompanied by enlargement and softening of the lymphatic glands behind the right ear and in the neck. At the bend of the elbow was a lupoid cicatrix fringed by nodules, and another with tubercular eruption on the dorsum of the hand and fingers. Many scars occurred elsewhere on the trunk and limbs. The patient had been under treatment at various intervals for ten years. Professor Lang thought that the ulcer on the cheek was carcinomatous, although its margins were not indurated or everted. It rapidly extended whilst under observation, the lymphatic glands also breaking down. Microscopical examination of the discharge from the ulcer revealed numerous epithelioid cells, some being large and round with thick cell-walls, others multiangular, or spindle-shaped, and various shapes presenting grooved nuclei (Furchungkerne), which Lang and Gussenbaur have shown to be characteristic of rapidly growing cancer, a character presented by the nuclei of cells of all rapidly growing organisms. Before death, which took place two months after the patient's admission, there was widespread ulceration of the whole cheek, laying bare the mucous membrane, and of the side of the neck over the diseased glands. Post mortem, secondary nodules were found in the pleuræ, left lung, and liver. The microscopical characters of the ulcer on the cheek are most fully detailed. They may be summed up here as presenting the characteristic lymphoid elements of lupus, arranged mostly in the superficial parts, but penetrated by ramifying "tubes" of cancer cells in the deeper layers. The small round cell forms of the lupus contrasted markedly with the large epithelioid cancer elements. The stroma of cancer was, as it were, formed by the lupus cells; but in no part was any transition between the two varieties of cells to be seen. From the disposition of the cancer cells it is concluded that they mostly had found their way from the blood and lymphatic vessels, some sections showing appearances exactly as if vessels were filled by these cells. Although he has frequently found overgrowth of the cellular elements of the walls of vessels in cancer, yet he has never traced a direct conversion of them into cancer cells. The paper concludes by attributing the terribly rapid evolution of cancer, when grafted on lupus, to the loose and soft nature of the lupoid tissue, the rapid disorganisation of the new growth being aided also by the low vitality of cancer cells—still more diminished by the slight nutrient value of the lupus material forming the stroma of the former.

ICES IN THE STREETS.

IT came out incidentally at the Marylebone Police-court on Wednesday, that a man selling ice-creams in the streets made seven or eight shillings a day. The reflection is distressing. Something like a hundred ices a day must have been consumed from his barrow to yield such a return. It would be interesting to ascertain the amount of suffering inflicted by an ordinarily prosperous member of this trade in cheap and nasty luxuries. There is no reason why the poorer classes should not be regaled with cooling delicacies. They need them quite as much as, perhaps more than, their superiors in social status. But the common street ice is a concoction of dirt and indigestibility which it would be impossible to describe and difficult to realise. Cooling drinks and frozen eatables need to be especially pure and good in themselves, in order to minimise the danger of bad consequences. It is sufficiently perilous to introduce a frigid mass suddenly into the stomach, but when to that risk is added the evil of having swallowed something which no persuasion would have induced a sober person to eat or drink if it were not frozen, the folly of the proceeding is intensified. It would not be worth while to notice the matter, but that the practice of consuming cheap ices is increasing largely among the industrial orders, and particularly domestic servants, who expend a really considerable proportion of their pocket-money on these supposed delicacies. It would be well if either a better article could be supplied, or more caution evinced in the gratification of a natural desire for something cooling and grateful to the palate. There is no valid reason why iced drinks and frozen sweets should be either so dear as to place them beyond the reach of all who are not tolerably well provided with cash, or so bad in quality as to be wholly indigestible.

THE REGISTRATION OF DISEASE.

DR. WALTER DICKSON, R.N., medical inspector of Her Majesty's Customs, gives in his last annual report some interesting statistical particulars, which exemplify in an eminent degree the importance of keeping accurate and systematic registrations of disease as it occurs in large communities of the adult population. The total force of Customs officers in London and at Gravesend under the medical care of the inspector amounts to 923 men. The mean daily number on the sick list was 30·7, or 6·4 of strength. The mean duration of each was, in London 28, and at Gravesend 11 days, the loss of time per man (including Sundays) being 13 days in the one case, and 10 in the other. The total death-rate was 2·1 per cent., and 1 per cent. only of superannuation. Both these last figures appear to us exceedingly low, having regard to the fact that these men are out at all hours in all seasons of the year, and are employed in work that in a sanitary sense may, as we remarked some three weeks ago, be fairly denominated as risky. Dr. Dickson says: "The health of the Customs officers in the year was doubtless fairly typical of that of the adult community, which at present can only be partially and imperfectly estimated through the death-rate. The main features of the period were the prevalence and severity of pulmonary complaints and rheumatism in the colder, and of gout in the relatively warmer months. The epidemic character of gout in conformity with the season among this class is specially noteworthy. A total of 39 cases occurred during the year, almost exclusively limited to the London division. It proved most obstinate among the watermen class, occurred irrespective of age, intemperate or abstemious habits, and was remarkably influenced by the weather, warmth and damp occurring in a generally dry season seeming to be especially favourable to its development." The absence of zymotic diseases is also particularly noted. We desire to draw attention to this, among other interesting phases of Dr. Dickson's report, because it is, as far as we know, the only attempt at the careful registration of disease among the civil adult population of this country, and to urge strongly that the example is, for sanitary and scientific purposes, well worthy of imitation. The General Post Office employs a very large and annually increasing staff, and its chief medical officer, as well as its various district surgeons, might furnish a large mass of valuable information. Sickness as occurring in the metropolitan and City police might be similarly classified and reported upon by their respective surgeons, and the medical officers of the great railway companies could add most usefully to the list. Such efforts, exemplified in the report now before us, would pave the way for that invaluable work—a complete registration of disease as well as of mortality throughout the kingdom.

THE USE OF CURARA.

The general use of curara in our physiological laboratories as a convenient instrument for experiments upon animals is attracting a good deal of attention, and much severe comment from the opponents of animal experimentation. It is believed to be an agent which destroys all power of movement, while it leaves the capacity for sensation and for pain unaffected. Such is the belief of physiologists at the present time, and it must be confessed that it is in that belief that they employ it, if not as frequently as is asserted, at any rate often enough.

The alleged sensitiveness of animals poisoned by curara does not seem to us, however, to rest upon a very firm foundation. When frogs are under the influence of a moderate dose, if one limb be, by interference with the blood-supply to it, withdrawn from the influence of the curara, movements occur in the limb when the skin of that limb or of the body is pinched; hence it is concluded that the sensory nerves are unaffected. But so does a frog whose head is removed. The movements must be entirely reflex. Moreover, the property of excitability of the sensory nerves is lost when the dose of curara is increased. It is only reasonable to suppose that the effect which curara in a large dose produces in a moderate degree, it produces to some extent in a smaller dose, and that the sensory perceptions of the animal are lessened to some extent by a dose which is sufficient to destroy the irritability of the motor nerves. It must not be forgotten that central sensibility is a very different thing from excitability of sensory nerves, just as voluntary power is a very different thing from excitability of motor nerves. A poison will paralyse the will which has not the power to destroy the irritability of the motor nerves, and it is not unreasonable to believe that the sensory centres of the animal are dulled, even though its sensory nerves remain irritable. Until this is very conclusively ascertained, the use of curara, while it may be discountenanced, should not be deprecated as the atrocious agent it is alleged to be.

A SMALL MATTER OF MOMENT.

It is not a pleasant thing to meet one of those covered litters, something between an elongated trunk and a coffin, in which sick paupers are removed from their beds at home to the workhouse; but there is at least a show of carefulness in the proceeding which almost reconciles the spectator to the clumsy performance of a good action. Nevertheless, why cannot parochial officials be induced to add to their grace the virtue of a trifling precaution? If only they would select able-bodied and well-conducted paupers as bearers, in place of weak, decrepit, or reckless beings, who inflict unnecessary suffering on their burden, there would be no additional outlay, and there would be a considerable gain in comfort to the sick and in public approval. Again, the bearers should keep step. This is a very small matter, but it is one of great moment to the person carried. Now that the old distich about jolting the dead bones of a pauper over the stones, because they happened to belong to a person whom nobody owns, is grown obsolete, it would be no sentimental excess of care to avoid subjecting the sick or the dying to a process not unlike churning, and quite as uncomfortable. Nothing more is requisite than to appoint strong and careful bearers, and teach them to step together like the bearers of a military ambulance.

THE LONDON HOSPITAL.

We learn that on Tuesday last, the House Committee of the London Hospital decided to postpone for three months any election to the post of assistant obstetric physician, though a vacancy had been declared and applications received. The rules of the hospital require every eligible candidate to be a member of the Royal College of Physicians, and some of the candidates had this qualification whilst others had not, and the committee, it would seem, after consideration, decided it would be best in the interests of the hospital to defer the election. We believe that in this departure from usual custom the committee were supported by the opinion of many members of the staff, who were naturally anxious to encourage one of the candidates who had not the legal qualification necessary, but who had distinguished himself greatly whilst a student, not only by taking prizes, but by clinical work, and had, moreover, shown by general conduct that he would most probably prove a desirable colleague. As this decision allows more than one junior candidate the opportunity to legally qualify for the appointment, the committee have probably acted wisely. It is to the interest of large institutions that junior staff appointments should be filled by men who can give a great deal of time to clinical work, for the benefit of both the patients and the students.

MEDICAL LEGISLATION IN NEW SOUTH WALES.

It is proposed to introduce a new Medical Bill for New South Wales. Dr. Smith, the Dean of the Faculty of Medicine in Sydney University, has given great offence in arguing for this Bill by asserting that there is such an amount of ignorance, unskilfulness, and intemperance among legally-qualified men that human lives are daily endangered by them. We can readily believe that these words are a misrepresentation of the state of medical education and character in the colony; but we must dissent from some of the arguments against Dr. Smith used by the *Melbourne Medical Record*, which says, "Why should Dr. Smith gird at the profession because some of them can't spell?—as if knowing how to spell made a doctor. Medicine owes more to quackery than members of the profession either know or would like to admit. The Pharmacopœia is nearly made up of quack nostrums." This is strange doctrine for a medical journal, "the only weekly medical journal in the Australian colonies." The sooner there is another, we should say, the better.

THE NORWOOD POISONER.

FIVE years may seem a long term of punishment for a man going about drunk, and with nothing but the recklessness of a drunken man dispensing poisonous doses of strychnine to everybody that was drunk enough to accept his hospitalities; but we are disposed to think it is not much too long. It is high time that the principle was more fully enforced, that if men will get drunk and be reckless, they must not count too much on the fact of their being drunk as an excuse for their being reckless. One life was sacrificed, and it is a mere accident that two or three more were not compromised by this drunken freak of Walter Thompson Hunt. The incidents of the case are a painful illustration of the day's work of a man who has the curious complicated generosity of a drunken man—first to make everybody drunk he meets with, and then to administer something to undo the drunkenness. We entirely acquit Hunt of malice. No doubt strychnia had been found by him to act as a sort of pick-me-up, and it is known to be a useful tonic for inebriates. But after making all allowances, we are not sorry that he will have five years to reflect on the value of human life and the criminality of recklessness. It is lamentable to note that not one word of information transpired at the trial as to the source from which the prisoner obtained the strychnia.

HOSPITAL SUNDAY.

EXPECTANT hospitals and dispensaries probably feel rather acutely the delay in the distribution of the Hospital Sunday Fund. It is certainly rather tantalising. But there is reason to hope that the delay will secure a better distribution, and obviate much of the dissatisfaction and adverse criticism which it is so desirable to avoid with a view to the satisfaction of all parties. It was resolved in the course of the warm but valuable discussions of the spring that in no case should the grant to an institution be reduced or withheld until after a conference with the managing committee of the institution. We are informed that seven deputations are to be conferred with on the 7th of October, and half-a-dozen more as soon as the committee can arrange to receive them. Further, it was resolved in May that before finally distributing the fund, the Committee of Distribution should present their report to the Council. After the conferences with institutions, then, the Council will have to meet and sanction the report. All this anxiety to secure a good distribution is justifiable, and we may confidently believe that the Distribution Committee, having now got the holidays over, will use as much haste as is consistent with good work.

OF BAD PROMISE.

THERE used to be a provincial proverb to the effect that the shoemaker's children were generally badly shod. Is it because the Government is entirely engrossed with the prosecution of sanitary reforms in the country that it so strangely neglects the surroundings of its own *employés?* The condition of many of the public offices is little short of a scandal to the authorities. Attention is afresh directed to the matter by the statement that Brigadier-General Campbell, C.B., is absent from the War Office on leave, "the atmosphere of the place" having affected his health. Not many weeks ago a public servant fell a sacrifice to the defect of ventilation in the British Museum. The new buildings in Parliament-street were for some time unoccupied because the escape of sewer gas into the apartments was unbearable. The War-office has long been notoriously ill-ventilated. It is time to protest against this very serious, and we must add disgraceful, state of things. A Government which prides itself upon being especially solicitous for the health of the people should show its care for the public welfare by showing some regard for the health of public officials. We cannot but feel that the present grievous neglect of internal affairs is of bad promise for the general work, and it is impossible not to experience concern and misgiving.

THE LATE DR. HUGHES BENNETT.

WE regret to have to announce the death of Dr. John Hughes Bennett, F.R.S.E., late Professor of the Institutes of Medicine at the University of Edinburgh. The subject of our memoir was born on the 31st August, 1812, and in 1829 was articled to a surgeon in Maidstone. Soon after he proceeded to Edinburgh, where, in 1837, he graduated with the highest honours as M.D. Dr. Bennett afterwards proceeded to Paris, where he studied for two years. He then left for some of the German schools, where he remained until 1841. Returning to Edinburgh stored with varied knowledge and experience, he soon acquired an influential position, obtaining, among other advantages, the post of lecturer on histology and the use of the microscope. In 1843 he was appointed pathologist to the Royal Infirmary, and five years after, on the resignation of Dr. Allen Thomson, he was nominated to the chair of the Institutes of Medicine in the University, a post which he held most worthily up to quite a recent date. Dr. Hughes Bennett furnished numerous and valuable contributions to medical literature, the most important of which is his book on Clinical Medicine. We hope next week to give our readers a further account of his life and good deeds.

THE LICENSING LAWS IN LIVERPOOL.

WE are glad to learn that the Liverpool police for the last two or three weeks have been most active in laying information against publicans who supply drink to drunken customers. The great disproportion between the number of convictions for drunkenness and the convictions of publicans for supplying drink is a disgrace to the police. The radical evil, however, in Liverpool, as elsewhere, is in the fact that the number of public-houses is out of all proportion to the wants of the public. Half of them could not be kept up if people only took what, on even a generous computation, they required. For this state of matters, so palpable in London, not the police, but the magistrates are to blame. The sooner some greater stringency is introduced into the system by which licences are granted and continued the better.

HEPATICO-BRONCHIAL FISTULÆ.

A CASE of fistulous communication between the liver and the right lung was recently described to the Société Médicale des Hôpitaux by M. Laboulène. Such a condition is in itself of great rarity, and the instance was further remarkable in the obscurity of the condition in which it arose. The common cause of fistulous openings between the liver-ducts and adjacent viscera is the rupture of either an abscess or an hydatid cyst of the liver, but in this case there was nothing to indicate the presence of either of these conditions. The patient was a man aged forty-six, of intemperate habits. For six months there was constant expectoration of bile, which had commenced suddenly without preceding illness or indication of liver trouble, but after the ingestion of a large quantity of beer. There appeared to have been no vomiting, no expectoration of pus or membrane or clear liquid. Examination six months after the commencement of the bilious expectoration showed slight enlargement of the liver, and some dulness at the base of the right lung, where loud râles could be heard. When he coughed some bile was expectorated, and the râles disappeared. With rest, regulation of diet and bowels, &c., the expectoration lessened, and in a few weeks disappeared, and the patient left the hospital well.

DR. HENRY BENNET.

THE month of October, which brings back the busily engaged members of our profession, renovated, we must hope, by their hard-earned holiday, will see the departure of one of our best-known London physicians from the arena of consulting practice. Dr. Henry Bennet, after thirty-three years' practice as a consulting physician, retires from London professionally. In 1849 Dr. Bennet's career was arrested by all but fatal illness, and he was obliged to surrender active work, and to retreat for the winter to the south of Europe. Here his energy did not abandon him. His works on the climate of the Mediterranean and on thoracic pathology are well-known books of reference.

THE FEMALE MEDICAL STUDENT QUESTION.

A CONFERENCE of the medical staffs of the General and Queen's Hospitals, and of the professors and tutors of Queen's College, Birmingham, was held on the 29th ult., on the question of the admission of women to a medical education, when it was decided by a majority of thirteen to nine, "That the professors and tutors of Queen's College, and the physicians and surgeons of the General and Queen's Hospitals, are not prepared to undertake the medical and surgical education of women." Under these circumstances the Council of Queen's College will have no alternative but to decline to receive female medical students.

WORCESTER INFIRMARY.

AT a meeting of the Worcestershire Medical Society, held Sept. 29th, 1875, it was resolved unanimously:—"This meeting has learned with much regret the differences which exist between the honorary medical staff and the Executive Committee of the Worcester Infirmary. Having confidence in the moderation of their professional brethren connected with it, this meeting assures them of their sympathy and approval in their attempt to obtain for themselves and their successors such protection by the rules as may be needful to secure them from unnecessary vexations in the responsible yet privileged position of honorary medical officers of that institution."

MEETINGS OF THE MEDICAL SOCIETIES.

WITH the opening of the medical session the time arrives for the renewed meetings of the various medical societies of the metropolis. The first society to commence proceedings is the Obstetrical, which meets on Wednesday next, the 6th inst. This is followed by the Clinical, on Friday, the 8th, and the Medico-Chirurgical on Tuesday, the 12th. The Pathological Society is the last in the field, its first meeting being appointed for Tuesday, the 19th. All these societies meet at half-past eight o'clock, with the exception of the Obstetrical, which begins at eight.

MR. JOHN SPEAR, medical officer of health, in presenting a report to the Jarrow Urban Sanitary Authority, describes an outbreak of enteric fever which made its appearance in the district in August last. In a few days thirty-four cases were reported, occurring in twenty different families. Of these more than half were of children. There was no difficulty in proving that the disease was caused by contaminated milk. Nearly all the sufferers had obtained their supply from the same farm. When the farm was visited six of the occupier's family, including himself, were down with typhoid. The water used in the dairy was derived from a well situated about eighteen yards from a privy and cesspit, the latter simply a hole dug in the ground, and in no way protected. Examination made it quite clear that soakage had been going on for a long time. The whole arrangements of the place were of a disgusting kind. There was direct communication between the dairy and a room in which some of the fever patients were lying, and the clothes of these patients were washed in the dairy.

THE late medical officer of health for Paddington, in issuing his last report on the condition of the district, animadverts on that long-standing nuisance, the Paddington Canal. Every attempt made to abate the evils connected with the foul and stagnant water of the basin had failed. House-dust, garbage, street sweepings amounting to hundreds of tons, and the manure of thousands of horses, were daily loaded into the barges in the canal. Analyses of the water made in July, August, and September showed it to be little better than sewage. It is surprising that the health of the inhabitants near the canal is so good, but sooner or later we fear epidemic disease will make its appearance.

WE are glad to hear that the Newcastle-on-Tyne Dispensary has been particularly fortunate within the last year as to its finances, a sum of over £12,000 having been added to its resources by legacies, including the munificent bequest of £10,000 left by the late Wm. John Hutchinson, Esq., of Newcastle. Various improvements are suggested in the working of the institution; not the least is that of Dr. Lyle, one of the honorary staff, who mentions the difficulty experienced by poor patients of the dispensary in obtaining instruments and surgical appliances.

THE Committee of Management of the Evelina Hospital for Sick Children appeal for increased support to enable them to receive forty-four additional patients. The committee would be glad to see a greater number of visitors to the hospital, and feel sure that a large amount of sympathy would be awakened by witnessing the sufferings and helplessness of the little patients, and the skilful and tender treatment they receive. One ward of the Evelina Hospital is expressly appropriated to cases of whooping-cough, and another is entirely set apart for Jewish children.

IN London 1319 deaths were registered last week, including 13 from measles, 90 from scarlet fever, 12 from diphtheria, 49 from whooping-cough, 18 from different forms of fever, and 125 from diarrhœa. No death from small-pox was recorded. In the large public institutions 200 deaths were reported, or 15 per cent. of the total mortality. The Fever Hospital at Homerton contained 281 patients on the 25th ult., 211 being under treatment for scarlet fever.

DR. DIVER, of Southsea, has received an official letter from the Humane Society of Boulogne, in which his services in crossing the Channel with Captain Boyton during his two trips are set forth in very complimentary terms.

WE understand that the Chertsey health authority have requested Mr. Birch, C.E., to make a survey of Bagshot, and prepare a report of its sanitary condition. It will be remembered that the district was visited by our Sanitary Commission some few months ago, when, although its very great natural advantages were described at length, the sanitary defects existing in the town itself were fully pointed out.

DURING the past month no less than five ships have arrived in the Thames with cases of scurvy on board, and seven or eight of the victims have been admitted into the Seamen's Hospital. The medical inspector of the Board of Trade has, by direction of the Marine Department, held official inquiries in three of these cases, but the result has not yet been published.

WE hear that cholera has broken out in the European camp at Delhi. It is, however, of a mild type, and it is confidently hoped that it will have disappeared long before the assembling of the troops forming a large part of our Indian army who are to meet the Prince of Wales outside the walls of the historic city.

IN the *Athenæum* for September 18th will be found an interesting article by Mr. Thoms on the Tring centenarian. Mr. Thoms strives to demolish the evidence offered by Sir Duncan Gibb in our columns towards establishing the great age of Elizabeth Leathurlund.

A YOUNG gentleman has been prosecuted by the Colemine Board of Guardians for exposing himself while convalescent from scarlatina. The Board deserves much credit for applying the law in this case.

IT is stated that the sanitary advisers of the Government of India have recommended that Simla be abandoned for three years on account of its unhealthiness.

WE are requested by Mr. Cripps, of Cirencester, to say that it was the Weymouth Sanitarium to which he alluded in his letter published in our columns last week.

FOOT-AND-MOUTH DISEASE.

THE reports relative to the foot-and-mouth disease show that it has abated nothing of its virulence, and that it is widely prevalent in England and Scotland, causing great inconvenience and immense loss, and in many districts leading to the suppression of cattle-shows. It is not likely that it will be much diminished in prevalence for some time to come, and if we could arrive at anything like a correct estimate of the loss it has caused this year, we should probably find that it amounted to more than a million at the very least.

In our previous article on the subject, we alluded to the principal causes which are in operation in extending this purely contagious malady, and we pointed out that the system of inspection—if such a designation can be applied where there is no system—is of very little value, inasmuch as the principal sanitary inspectors are the police—men no doubt worthy of reliance in their own special sphere, but neither by their knowledge nor training fit to be entrusted with the control or suppression of contagious diseases, either human or animal. The Annual Report of the Veterinary Department of the Privy Council for 1874 fully corroborates our statement in this particular, as we are informed that on the 31st December last there were 1706 inspectors holding appointments under the local authorities, and of these 371 only were veterinary surgeons (it is not mentioned whether they were all qualified), 1021 were officers of police, and "314 appeared to have possessed no special qualification for the office." Without inquiring whether the police officers themselves possessed any special qualification, we may point out that less than one-fourth of the total number of inspectors were veterinary surgeons; and when we know that these are generally only called in now and again to verify the existence of certain contagious diseases, and have, as a rule, nothing to do with tracing the history of these, nor advising as to their suppression, we need not be surprised that this malady in particular is just as active, and as free to spread, as if we had no Veterinary Department and no inspectors.

It appears to be imagined that anyone can perform the duties of an inspector, and that, as the police are already in pay, and their duties are not particularly heavy, they might as well have this work thrown on them. We need scarcely say that a greater mistake could not be made. It requires well-trained and thoroughly competent veterinarians to perform the functions of an inspector efficiently; for not only have these subtle maladies to be thoroughly stamped out wherever and whenever they appear, but their invasion or re-introduction has to be guarded against, and their mode of access closely watched. Indeed, from what we know of these contagious diseases, and from what we see of the trade in animals and the manner in which it is conducted, we are convinced that nothing beneficial can be done until veterinary surgeons—and the very best of them—are appointed to take charge of districts at a liberal salary, with the view of protecting the public from the ravages of these scourges. The attempts now made in this direction would be amusing were the results not so painfully serious. The Veterinary Department of the Privy Council must be roused up from its supineness and apathy, and made to see that its existence depends on its usefulness. Hitherto it has been of very little service to the country; it leaves everything to the local authorities, and the majority of these either know or care little about the matter, or try to get the work of inspection done for next to nothing.

In the meantime, as the reforms which are so urgently required are not likely to be instituted until more millions of pounds are lost, it may be useful to indicate what should be done in the way of prevention or cure by those whose stock is menaced or already invaded by this "foot-and-mouth" complaint. These indications we will summarise from Mr. Fleming's "Manual of Veterinary Sanitary Science and Police."

Newly-purchased animals, and especially those which have been exposed at fairs or markets, or travelled by boat or rail, should be quarantined in some convenient place apart from other stock, and no communication should take place between them for at least six days. Forage from infected districts should be interdicted, unless it is proved that it cannot possibly be tainted; and no persons or articles from infected stables or pastures should be allowed to go near healthy animals.

As a rule, few animal diseases are more amenable to treatment, and still fewer exemplify the beneficial effects of hygienic measures, than this. When it has appeared, the sick animals, if at pasture, should be housed and allowed to stand on some soft material, such as sawdust. If they cannot be sheltered, then they ought to be put on firm grass land. Soft succulent food, mashes and nourishing gruel, must be the diet while the mouth is sore, and bran gruel, or water slightly acidulated, given to drink. If the fever runs high or constipation is present, treacle, Epsom salts, or common salt may be gently administered. Laving the mouth in cold water (which may be slightly acidulated) is grateful when the eruption is slight, but when the erosions are extensive and painful, gargles of vinegar-and-water, hydrochloric acid, honey-and-water, or a weak solution of tannic or gallic acid (one ounce to the gallon) are necessary. Lime-water is a good dressing when the ulcers are deep. When the feet are affected, and even before they are involved, they may be dressed with carbolised glycerine, a weak solution of carbolic acid, or any mild astringent. It is frequently very beneficial to send the animals into a shallow running stream to bathe their feet; but when these are affected, it is better, as a rule, to allow the animals to rest as much as possible. When suppuration occurs beneath the hoof, or the feet are severely involved, it is advisable to procure the services of a veterinary surgeon.

Great cleanliness and thorough disinfection must be advocated, both during the prevalence of the disease and after it has disappeared. In many farms and cowsheds the active germs of the malady are allowed to remain, and cause repeated outbreaks.

But, we repeat, the therapeutical treatment of the disease is altogether a secondary affair; its prevention and absolute extinction are what we must insist upon; and the matter is now assuming such a grave aspect, both in a pecuniary and sanitary point of view, that we feel convinced that nothing less than an efficient organisation to effect this object, and to stamp out other serious animal contagions, will now satisfy the public. The present temporising policy with regard to these destructive pestilences has been tried for now nearly ten years, and has proved notoriously useless. It is high time a common-sense view was taken of the matter, and measures adopted which would relieve us from these heavy annual losses and panics.

THE MEDICAL HISTORY OF THE DUTCH WAR AGAINST ATCHEEN IN 1873.

(Concluded from page 453.)

Sanitary Experiences of the Expedition.

THE surgeon-in-chief strongly recommends that in future on shipboard the Europeans should be supplied with thin mattresses and pillows, and the natives with mats.

The first night on shore found the troops without any protection, there being no time for extemporising huts or tents, besides which an immediate change of camp was foreseen to be unavoidable from the proximity of a graveyard to the superficially lying ground-water of the locality.

In the new camp all kinds of skeleton huts were erected as a defence against the heat, which was distressing more from its uniformity than its actual intensity. No unfavourable influence was noted in the camp of the field column. The waterproof sheets of the officers were very useful to protect both from rain and from the ground-damp of the rice-fields.

The troops while on board the steamers were excellently fed, according to the contract with the Netherlands and Ostend Steamship Company.

From the first day of landing fresh meat was served out, and it was agreed between the authorities and the surgeon-in-chief that live stock should be provided, so that once a week recently killed meat should be substituted for the Australian beef. It would be a most advisable thing that, in the rationing of troops, the salted and smoked flesh, as bacon, &c., should be entirely replaced by Australian meat.

The best drink for troops on the march was found to be cold tea; the dangerous properties of strange water are destroyed by boiling, and the objectionable taste of boiled water corrected by tea.

On the return voyage, water brought from Padang by one of the invalid ships sent thither was for the most part used. At the same time, on all ships it was ordered that only cold tea should be drunk, and the very rare occurrence of diarrhœa speaks for the judiciousness of this rule. Alum as a means of clearing water was rejected, purification by sesquichloride of iron and bicarbonate of soda being substituted.

In clothing and equipment there is much room for improvement. The use of sun-covers to the ordinary head-dress is much to be condemned, since the back piece hanging down obstructs the air and heats the back of the neck, besides which, from being too broad and too long, they enclose the ears, and the words of command are not heard. For this reason many of the men put up the back pieces. For service such as this wicker helmets should invariably be procured. The haversack was also a great hindrance, since by swinging to and fro it impeded the man's progress; and it is only fair that when engaged against an unencumbered enemy, as here, the men should be relieved of all impediments, carrying only their weapons and ammunition, and a rolled coverlet capable of containing a change of linen.

Esmarch's triangular bandage was served out as part of the kit of each man, but its application by the men was not necessary, as surgical assistance did not fail; this, however, does not lessen the value of the appliance.

The Care of the Wounded.

As a rule the wounded were attended immediately after the fight. Only on the 16th April, when 117 were wounded, was there any delay, and even then the severely injured were in camp by midday. Fresh meat, vegetables, milk, seltzer water, &c., were liberally supplied for their use.

The splints of split bamboo were in many cases of complicated wounds of much service, but especially was the quantity of pasteboard valuable for hurried bandages. The plaster-of-Paris bandage could not be made to set either at the seashore ambulances or on board the hospital ship, a defect which must have been caused by the excess of atmospheric moisture, since the same material hardened perfectly when used on returning to Batavia.

The tandus, as stretchers, were superior to all others; the wounded did not roll in them as on the broader ones, and two coolies were sufficient to carry them, besides which water could be brought in the hollow bamboo. The objection of their not affording an even surface for fractures of the lower extremity can be guarded against by the previous application of splints, and it is maintained that even unset fractures can be conveyed in them. If broken they can easily be replaced, and may be extemporised from mats or waterproof sheets.

The hospital coolies ought always to be marked with a distinctive badge, as otherwise in the confusion of an engagement they mingle with the other coolies and disappear.

The European hospital *personnelle* won by their courage and endurance unanimous commendation; but for a big war special sanitary companies are indispensable.

The principle of taking invalided men, unfit for active service in the ranks, is in the highest degree reprehensible.

The judgment pronounced on the service rendered by the coolies proves it to be necessary that for the hospital service there should be *well-disciplined soldiers*, since only a hospital corps trained and schooled as other bodies of soldiers can perform the required duties. The opinions of military surgeons in all armies agree on this question, and it is to be hoped that this universal accord will in time overcome existing prejudices.

In the Ambulance.

By the timely evacuations of sick and wounded to Batavia, overcrowding of the ambulance on shore was prevented. It was capable of accommodating 100 patients, and only for three days, from the 16th to 19th April, were all the beds occupied. 97 sick in all were treated in the ambulance, not counting those detained only for one or two days before removal to the hospital-ship.

On the Hospital-ship.

During the short time from the 22nd March to the 10th May 403 patients were treated; of these 152 were cases of severe wounds. As a protection for sick a ship is, above all, the most undesirable, since only by the constant use of windsails, by forming side-wall openings, and by turning the ship square to the wind, could anything like adequate ventilation be secured. An additional evil was that the ship carried cargo as well as hospital equipment; planks and bamboos were stowed away in the damp hold, which on being taken out caused a most disagreeable stench. Worse still, dried fish for the native sailors was packed under the wards, and only discovered by the surgeon-in-chief perceiving the smell when making an inspection.

The number of sick made sanitary efforts most pressingly necessary. With this view the boards of the sick decks were daily well swept, cleaned, and sprinkled with carbolic acid and water, half a bottle of the red acid to a bucket of water; while day and night the vapour of carbolic acid was continuously produced by the following means: sand impregnated with carbolic acid dissolved in alcohol, in the proportion of eight ounces to ten pounds of sand, was sprinkled over the floor, and from this a constant exhalation of carbolic acid took place. All soiled dressings and excreta were at once disinfected and disposed of, and every attention paid to cleaning the clothes of the wounded.

For the disposal of the dead from the hospital-ship the body was wound round with 25 lb. of old iron chain, enclosed in canvas, and dropped into the sea. This was preferred to shot, as the latter sank to the bottom of the bag, which, by friction against the coral reefs, was quickly cut through; the shot then fell out, and the body floated. As it was no corpse ever came to the surface by Atcheen.

Return of Sick and Wounded.

Sick: 542 (proportion to strength, 15 8 per cent.); of these 27 died, being about 5 per cent.—*Wounded:* 50 killed (proportion to strength, 1·4 per cent.); 421 wounded (proportion to strength, 12·8 per cent.) Of their wounds 33 died, being less than 8 per cent.

The relative frequency of sword wounds to shot wounds was as 15 per cent. to 81 per cent.

The 421 wounded received in all 487 wounds, which, as regards the part of the body injured, were as follows:—

	Per cent.	Actual number.
Head wounded	12·7 ...	62
Face	9·6 ...	47
Throat and neck	2·6 ...	13
Breast and back	7·8 ...	38
Abdomen and loins ...	2·8 ...	14
Pelvis	3·6 ...	18
Upper extremity	34·4 ...	168
Lower extremity	25·9 ...	127
Of sickness superadded to wounds 6 died.		487

On the whole the treatment of the wounded was most successful, since, out of 421, only 33 (7·8 per cent.) died. Of those which proved fatal, 7 were breast wounds, 5 head, 1 abdomen, 3 knee, all of which were penetrating.

The most remarkable fact connected with this expedition was the total absence of typhus fever and pyæmia from their hospitals up to the time of their return to Batavia. "Notwithstanding the overcrowding of the hospital-ship with severely wounded, some of whom suppurated profusely, neither at Atcheen nor up to the re-arrival in Batavia had anyone died of pyæmia." The reasons for this exemption were recognised by the surgeon-in-chief in the care for ventilation, the scrupulous cleanliness of the places for the wounded on the decks, the plentiful supply of food, and the attention paid to dressings, which were changed many times a day when required. Also the three several evacuations of the wounded contributed to the happy result.

The operations performed were in all eleven:—*Disarticulations:* 1 left arm (died of exhaustion after healing of the wound; was an opium-eater); 1 right arm; 2 fingers.—*Amputations:* 2 left arm and 2 right arm (2 died); 2 right thigh (1 died of pyæmia in hospital at Batavia, 1 died of secondary hæmorrhage); 1 forearm.

By deducting the three cases which ended fatally under special circumstances a successful operative result is claimed, but the paucity of operations would testify rather to the fortunate issue of conservative treatment.

The Atchinese used their tulwars with great effect; in many cases the skull was cut through and the brain exposed. In one instance four fingers were cut off, in another a hand, and in a third both bones of the leg were severed without splintering, at one blow. The projectiles of the Atchinese were chiefly leaden, with a piece of porcelain or coral inside.

The best evidence of the sanitary success of this expedition is afforded by the detail of inward illnesses, of which only 187 cases were admitted during the whole campaign, and but five of these died. Fevers, however, increased to a considerable extent during the return voyage to Batavia, yet were for the most part of a mild type. Diarrhœa and dysentery, which have ever previously been the certain accompaniments of such undertakings, were almost entirely absent, and the few cases that did occur were especially amenable to treatment.

Correspondence.

"Audi alteram partem."

MEDICAL EXPERTS IN THE DAILY PRESS.

To the Editor of THE LANCET.

SIR,—THE LANCET has so consistently condemned the practice of medical men rushing into the daily press, that I venture to ask your attention to an instance which appeared in *The Times* of yesterday under the sensational heading "Homicidal Lunacy":—"I have received," writes Dr. L. S. F. Winslow, "through the courtesy of one of the leading lunacy authorities in Scotland, formerly a Commissioner in Lunacy, full details of 'the Cambuslang murder' to express an opinion on, and I trust you will allow me to do so in *The Times.*"

It is apparent that my old friend, Dr. W. A. F. Browne, is here indicated. I cannot for an instant believe—as this extract would imply—that he ever thought of seeking the opinion of Dr. Winslow on a difficult psychological question; still less that he sanctioned this appeal to the public through *The Times,* on a matter of life or death at the moment under the consideration of the Home Secretary. As a writer in the *Pall Mall Gazette* the same evening remarked, this letter should have formed the subject of a private representation to Mr. Cross.

But what I wish now to notice is the rashness—excusable only on the plea of youthful inexperience—which has led Dr. Winslow thus to constitute himself the judge of a difficult medico-legal case, which he has neither seen nor examined. It is really too absurd. "Sancta simplicitas," says Mephistopheles, "bezeugt nur ohne viel zu wissen." "I do not see," writes Dr. Winslow, "how there can be two opinions in the case"—my own sentiment precisely with regard to the presumption which dictated this letter in *The Times.*

I am, Sir, your obedient servant,

London, September 25th, 1875. F. R. C. P.

To the Editor of THE LANCET.

SIR,—Dr. L. S. Forbes Winslow's letter to *The Times* of the 24th instant about the Cambuslang murder opens with a statement which is—doubtless unintentionally—misleading, and which I should be glad to have an opportunity of correcting. He says that "the full details" of that murder have been received by him through "the courtesy of one of the leading lunacy authorities in Scotland, formerly a Commissioner in Lunacy, *to express an opinion* on." As my father, Dr. W. A. F. Browne, is the only ex-Commissioner in Lunacy in Scotland, it must be he to whom Dr. Forbes Winslow refers. I am in a position to state that he sent to Dr. Forbes Winslow a newspaper containing the report of the trial, but that he did not request any judgment thereon. He ventured to form his own opinion of the case without any extraneous assistance.

I am, Sir, your obedient servant,

West Riding Asylum, Wakefield,
Sept. 29th, 1875.
J. CRICHTON BROWNE.

ALBINOS.

To the Editor of THE LANCET.

SIR,—A remarkable case of the existence of four albinos in one family has recently fallen under my observation, which, with your permission, I should like to place upon record.

They are all children, of the ages of twelve, nine, four, and two respectively, three of them being of the male sex, and are typical specimens of their class; one description, therefore, will serve for all—viz.: The eyes present the well-known waving or restless condition of the muscles of the orbit, but are not so intolerant of light as in most cases. The pupils are of average diameter, and of a deep pink colour of great purity. The hair is of the softest texture, like the finest floss silk, and of the most exquisitely white and silvery colour, being luxuriant in its growth. The children, so far from exhibiting any of the mental deficiency noticed by some observers, appear to possess more than ordinary intelligence, and are well developed.

The parents are each thirty-seven years of age, and belong to the agricultural labourers; they are dark, swarthy people, and can offer no suggestion as to the cause of their children's peculiarity, there being no family history of the like on either side.

Other children not albinos have been born to them, and it is curious to note the order of succession. Thus, the first child was dark; second, albino; third, dark; fourth, albino; fifth, dark; sixth, dark; seventh, albino; eighth, albino; ninth, dark.

If any of your scientific readers would like to see them, they can be found at No. 96, Whitechapel-road.

I am, Sir, yours truly,
W. Sedgwick Saunders.
Queen-street, Cheapside, E.C., Sept. 29th, 1875.

AN AID TO THE OPERATION FOR STRANGULATED HERNIA.

To the Editor of The Lancet.

Sir,—Probably most surgeons who are familiar with the operation for the relief of strangulated hernia, in private practice, at night, have felt the want of skilled assistance in addition to that afforded by the practitioner whom they meet in consultation. This gentleman is fully occupied in the administration of an anæsthetic, whilst some friend of the patient is able at most to hold a candle. This need of additional help has been very frequently experienced by myself, and was also observed by Mr. Francis Toulmin, of Clapton, whom I met in consultation on the 19th ult. In discussing the subject we agreed that some kind of speculum, to hold apart the edges of the wound, would much avail. I have taken the most simple—*i.e.*, the common eye speculum—as a pattern. This has been made for me, of stouter wire and of twice the ordinary size, by Messrs. Kröhne and Sesemann. I think some such device as this will prove very useful to the operator.

I am, Sir, your obedient servant,
C. F. Maunder,
Queen Anne-street, W., Sept. 21st. Surgeon to the London Hospital.

THE LATE DR. HUGHES BENNETT.

To the Editor of The Lancet.

Sir,—The lamented death of this distinguished physician induces me to remind his numerous old pupils that a bust of him was presented in August last to the University of Edinburgh.

The committee are anxious to present a replica to the new infirmary at its opening, and for this purpose a sum of £60 or £70 is still needed. Subscriptions will be gladly received by Dr. A. P. Stewart, 75, Grosvenor-street; Dr. Andrew Clark, 16, Cavendish-square; Dr. McKendrick, of Edinburgh, or by myself. I am, &c.,

Great Charles-street, Birmingham. Lawson Tait.

WINCHESTER SCHOOL.

To the Editor of The Lancet.

Sir,—I beg permission to correct some inaccuracies in that part of your Commissioner's report which refers to the dormitories and meals of the Winchester scholars. In addition to the old dormitories there are four modern ones, smilar to those in the Master's boarding-houses for commoners. Only thirty-two scholars sleep in the old dormitories, some of which are no longer used as sleeping apartments. All the bedsteads are iron, the boys drink out of tumblers and eat off plates; they have, in addition, wooden trenchers for their bread. I have known Winchester forty-five years, and never even heard of a boy drinking out of a "black-jack." I believe that specimens of "jacks" and trenchers are exhibited to visitors, hence, I presume, the error of your Commissioner.

I am, Sir, yours faithfully,
Godfrey B. Lee.
New College, Oxford, September 26th, 1875.

IRELAND.

(From our own Correspondent.)

The births registered in Dublin for the week ending 11th September amounted to 140, and the deaths to 144. The average numbers in the corresponding week of the previous ten years were—births 160, and deaths 155. The mortality from diarrhœa was 19; all of the fatal cases, except one, occurred in children. But two fatal cases of small-pox were registered in Dublin since 20th March last; none since 22nd May.

A good deal of objection continues to be urged in different quarters, for various reasons, against continuing to use the so-called "Dean Swift's Cabbage Garden" for interments. W. R. W. writes to the morning journals pointing out the error of calling the place in question "by the name it derived from the class of resurrectionists of former days." He states the proper name for this very ancient ecclesiastical enclosure was *Jardin des Capuchines*—the Garden of the Capuchins,—where a community of that order had an establishment. Dean Swift had no cabbage garden there, but owned an orchard, which has been alluded to in his writings, and which existed to the rear of the present Meath Hospital, in part of the locality formerly occupied by Keeffe's Nursery. Many of the tombstones appear of considerable antiquity, the inscriptions being quite effaced by age. The date on one was 1685. Adjoining this graveyard, on the north, is a smaller one belonging to the descendants of the French Huguenots. There are at least two other small burial-grounds belonging to the same class in the south part of the city of Dublin. Intramural burial should be entirely forbidden; the presence of rather a severe form of autumnal diarrhœa ought to quicken a movement in this direction.

The Factory Acts Commissioners, Sir James Fergusson, Lord Frederick Cavendish, M.P., and the O'Conor Don, M.P., are at present sitting at the Shelbourne Hotel. Several witnesses made startling statements as to the existence in Dublin of the "sweating system." We have reason to believe that the pictures drawn by the witnesses are by no means over-coloured. It is to be hoped that the result of the labours of the Commissioners will tend to provide better workrooms for the many minor factories in Dublin, and that a system of compulsory education may be provided for the young. The state of the tenement houses and of the labouring classes generally in Dublin much needs improvement, without which physical and moral degradation can but progress.

A meeting of the Senate of the Queen's University was held at Dublin Castle on Wednesday, the 15th ult., at which the following examiners were appointed:—Benjamin G. M'Dowel, M.D., examiner in medicine; Anthony H. Corley, M.D., examiner in surgery; William Roe, M.D., examiner in midwifery; Charles F. Moore, M.D., examiner in materia medica; Matthias O'Keefe, M.A., M.D., examiner in medical jurisprudence.

Dublin, Tuesday, Sept. 21st, 1875.

Diseased Horses.—At the Lambeth Police-court lately a case was brought before the magistrate under the Contagious Diseases (Animals) Act. The landlord of a tavern in Brixton was summoned, at the instance of the Metropolitan Board of Works, for neglecting to give notice that he had in his possession a bay mare affected with glanders or farcy. It was proved that the animal never had been affected with either disease, and that the cause of its death was non-infectious fever. There was no other course left the bench than to dismiss the case.

Medical News.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Sept. 23rd :—

Jackson, Ernest Carr, Harley-street.
Scott, William Edward, Robert-street, Hampstead-road.

The following gentlemen passed the Primary Professional Examination on the same day :—

Dell, Joseph Francis, Guy's Hospital.
Harvey, Thomas Prickard, London Hospital.

At the Preliminary Examination in Arts held at the Hall on Sept. 24th and 25th 145 candidates presented themselves, of whom 32 were rejected, and the following 113 passed and received certificates of proficiency in General Education :—

First Class (order of merit).—1. F. S. Pridden. 2. C. Ellaby. 3. A V. Bernays, F. C. B. Butler, J. F. Easmon, S. de C. Elmsall, P. Garrard, C. J. Harper, W. L. Pruen, F. C. Selous, C. L. Stow, E. G. Williams, and G. J. Wilson.

Second Class (in alphabetical order). — C. D. Adam, J. B. Adams, R. A. Bazire, D. Bennett, E. J. Biden, R. A. Billiald, A. Bosanquet, H. Bourcheier, J. L. Bousignac, P. Brown, C. G. Bunn, H. P. Butler, S. Butterworth, J. F. Caddy, J. A. Caldwell, G. H. Capes, H. W. Carr, W. J. Clarke, E. S. Cockell, W. S. C. Collins, C. A. R. A. Colmer, E. R. Cree, W. H. Crosse, H. W. T. Crow, B. H. Dale, E. Davies, J. D. Davies, W. J. S. Davis, P. H. Day, B. J. Dorrian, J. M. Douglas, J. B. Dreaper, H. W. Edis, F. W. Elliott, E. Evans, E. Farmer, S. Farmer, W. A. Fenton, J. W. Field, H. E. B. Flanagan, C. L. Gill, G. T. Girdler, P. Hall, J. Hammond, E. Hazel, N. Hildyard, F. Hitch, W. Holt, A. R. Jacobs, F. Jones, G. M. Jones, R. B. Knowles, T. L. Laxton, F. R. le Cocq, A. Lee, J. J. Lewis, R. Lewis, J. P. Litle, E. H. Locker, L. Mark, L. Matheson, G. McKee, E. J. Moberly, Peter Monti, H. Parsons, W. H. C. Payne, J. H. Powell, Z. Prentice, F. W. Prideaux, J. D. Priest, T. Rhodes, J. T. Richards, J. M. Rogers, C. Rowley, R. F. Shaw, W. E. Sicard, G. E. Skinner, A. Slate, W. Slater, S. Smyth, A. Sharland, W. C. Steele, W. H. Sturge, C. A. A. Taylor, A. B. Thorald, F. F. Thorne, A. W. Veness, A. J. Verrall, J. E. Viney, J. Waldron, A. Ward, G. B. Waterhouse, F. S. Watson, J. G. Webb, W. S. Webb, J. Whitehouse, R. J. P. Wilson, O. Withers, and F. Woore.

The Royal Aquarium and Summer and Winter Garden at Westminster is rapidly approaching completion. It will be opened to the public in December next. Last Tuesday a luncheon was given in the building to a large number of noblemen and gentlemen interested in the scheme. It will prove, we are sure, a great boon to London. The educational facilities of such an establishment are not to be lightly estimated.

The Privy Council and the Foot-and-Mouth Disease.—The Clerk of the Peace for the county of Warwick has received a communication from the Privy Council Office in reply to an expression of opinion by the local authority of Warwickshire to the effect that they ought to possess the power of stopping sales, fairs, and markets when they find the occasion, in their opinion, sufficiently urgent. Their lordships express their concern at the prevalence of foot-and-mouth disease, not only in Warwickshire, but in the country generally, but state that they are not prepared to put in force so extreme a measure as stoppage of sales and fairs on that account. In conclusion their lordships express an opinion that a severe application of the powers vested in local authorities will be found sufficient to reduce the disease to such proportions as will admit of ordinary legislative remedies to be obtained when the country is comparatively free from the disease.

Medical Appointments.

Alcock, J., M.R.C.S.E., has been appointed Medical Officer of Health for the Burslem Urban Sanitary District, vice Goddard, resigned: £50 per annum to commence with.

Austin, Mr. T. F., has been appointed an additional Hon. Dental Surgeon to the Liverpool Dental Hospital.

Bourke, G. J., L.R.C.S I., L.M., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Shercock Dispensary District of the Bailieborough Union, Co. Cavan, vice Rooney, resigned, and appointed to the Kingscourt Dispensary District.

Bower, D., L.F.P. & S. Glas., has been appointed Resident Medical Superintendent of Saughton Hall Asylum, near Edinburgh.

Brown, P., M.D., has been appointed Medical Officer and Public Vaccinator for the Winlaton District of the Gateshead Union, vice Megget, resigned.

Brownrigg, T. H., L.R.C.P.Ed., L.R.C.S.Ed., L.M., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Moira Dispensary District of the Lurgan Union, Co. Armagh, vice Anderson, resigned.

Corley, A. H., M.D., has been appointed second Examiner in Surgery at the Queen's University in Ireland.

Davidson, A. D., M.D., has been appointed Assistant Professor of Materia Medica at the University of Aberdeen.

De Denne, T. V., L.R.C.P.Ed., M.R.C.S.E., has been appointed Assistant Medical Superintendent of the Bristol Lunatic Asylum, Stapleton, vice Dickson, resigned.

Dougall, J., M.D., C.M., has been appointed President of the Glasgow Southern Medical Society for 1875–76.

Douglas-Lithgow, R. A., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Government Medical Inspector for the Port of Wisbeach.

Dunstan, R., M.R.C.S.E., has been appointed Medical Officer of Health for the St. Ives, Cornwall, Urban Sanitary District.

Fulshaw, R., M.R.C S.E., has been appointed Certifying Factory Surgeon for Earl-Shilton, vice Spencer, deceased.

Knox, T., L.R.C.S.I., L.K.Q.C.P.I., L.M., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Maguirebridge Dispensary District of the Lisnaskea Union, Co. Fermanagh, vice Johnston, resigned.

M‘Dowel, B. G., M.D., has been appointed second Examiner in Medicine at the Queen's University in Ireland.

M‘Kendrick, J. G., M.D., has been appointed an Examiner in Medicine at the University of Aberdeen for the ensuing year.

Moore, C. F., M.D., has been appointed second Examiner in Materia Medica at the Queen's University in Ireland.

Moore, J. B. G. G., L.R.C.P.L., has been appointed Medical Officer and Public Vaccinator for the No. 4, or Leigh District of the Martley Union, vice Taplin, resigned.

Morris, B. R., M.D., M.R C.P.L., has been appointed Physician to the new Hospital for Women, Nottingham.

Moutray, C. D., L.R C.P.Ed., L.R C.S.I., has been appointed Medical Officer and Public Vaccinator for the Ballyroan Dispensary District of the Abbeyleix Union, Queen's County, and Medical Attendant to the Royal Irish Constabulary, vice Walshe, resigned.

Murray, F. R., L K Q.C.P.I., L.R.C.S.I., has been appointed House-Surgeon to the Southport Infirmary, vice Potts, resigned.

Newby, T., M.D., M.R.C.S E., has been reappointed Medical Officer of Health for the Great Grimsby Urban Sanitary District for one year.

O'Connor, Mr. T., has been appointed Apothecary to the Cavan Union Workhouse.

Ogston, A., M.D., has been appointed an Examiner in Medicine at the University of Aberdeen for the ensuing year.

Ogston, F., jun., M.D., has been appointed Assistant Professor of Medical Jurisprudence at the University of Aberdeen.

Riley, J. St. P., M R C.S.E., L.M., has been appointed a Medical Officer to the new Branch of the Salford and Pendleton Royal Hospital and Dispensary, Manchester.

Rodger, J., M B., C.M., has been appointed an Examiner in Medicine at the University of Aberdeen for the ensuing year.

Roe, W., M.D., has been appointed second Examiner in Midwifery &c. at the Queen's University in Ireland.

Smith, P. B., M.B., has been appointed Assistant Professor of Chemistry at the University of Aberdeen.

Smith, R., M B., has been appointed Assistant Professor of Anatomy at the University of Aberdeen.

Stewart, Mr. C. T., has been appointed Stipendiary Assistant Dental Officer to the Liverpool Dental Hospital.

Tindal, D., L.F.P. & S. Glas., has been appointed Vice-President of the Glasgow Southern Medical Society for 1875–76.

Births, Marriages, and Deaths.

BIRTHS.

Clouston.—On the 25th ult., at Tipperlinn House, Morningside-place, Edinburgh, the wife of T. S. Clouston, M.D., F.R.C.P.Ed., Physician-Superintendent of the Royal Edinburgh Asylum, of a son.

Easby.—At North Villa, Darlington, the wife of W. Easby, M.D., of a daughter.

Fox.—On the 19th ult., at Widford, near Chelmsford, Essex, the wife of Dr. Cornelius Fox, Medical Officer of Health for East, Central, and South Essex, of a daughter.

Meikle.—On the 21st ult., at Strathearn House, Crieff, the wife of Thos. H. Meikle, M.D., of a son.

Royds.—On the 24th ult., at Reading, the wife of Wm. Royds, L.R.C.P.L., of a daughter.

MARRIAGES.

Lloyd—Meadows.—On the 23rd ult., at Christ Church, Kingstown, John Lloyd, M.D., Surgeon Bengal Medical Service, to Mary Lloyd, daughter of Joseph Meadows, Esq.

Smith—Crampton.—On the 25th ult., at Christ Church, Highbury, Wm. J. Smith, M.B., to Louisa, younger daughter of Thomas Hill Crampton, Esq., of Highbury.—No Cards.

DEATHS.

Braund.—On the 21st ult., Marian, the dearly beloved wife of James Montague Braund, Esq., of Hill House, Stratton, North Devon, in her 40th year.

Derbyshire.—On the 20th ult., at Stockport, Wm. Derbyshire, M.R.C.S.E., aged 61.

Dickinson.—On the 27th ult., Joseph, the second son of the late W. F. D. Dickinson, M.R.C.S.E., of Fountain-street, Ulverston, aged 29.

Evans.—On the 22nd ult., at Bristol, J. J. Evans, F.R.C.S.E., aged 67.

Home.—On the 17th ult., at Mount Æolus, Portobello, A. G. Home, M.D.

Keddell.—On the 18th ult., at Aylesford, Wm. F. Keddell, M.R.C.S.E., aged 48.

Leech.—On the 22nd ult., at Chichester, Edward Leech, M.R.C.S.E., aged 75.

Robinson.—On the 22nd ult., at Poplar, Chas. Robinson, Surgeon, aged 70.

Sutherland.—On the 9th of Aug., at Uitenhage, Cape of Good Hope, Wm. Sutherland, M.B., C.M., aged 40.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

THE SELFISH PRINCIPLE AND INFECTIOUS DISEASE.

ONE of the Bristol papers, the *Western Daily Press*, gives Dr. Spencer, of Clifton, Physician to the Infirmary, much praise for betaking himself, or allowing others to take him, as a paying patient to the Bristol Sanitary Authority Hospital, St. Philip's Marsh, when attacked with small-pox, caught from an infirmary patient shortly before the meeting of the British Association, at which Dr. Spencer had to act as President of the Physiological section. Dr. Spencer's example was a good one worthy of being followed. We are glad to think that such action as Dr. Spencer's is becoming increasingly common, and that, in London, at any rate, the better class of patients are increasingly showing their intelligence and their unselfishness by allowing themselves to be removed to the private wards of the London Fever Hospital, where every comfort and convenience is provided, associated with good medical attendance and nursing. The selfish principle is most tested perhaps at the end of infectious diseases, where the patient seeks air and change, and yet where reckless movements on his part involve the carriage of infection and often death, conveyed furtively in cabs or omnibuses or railway carriages, and in hired apartments. There is a law against such movements made recklessly; but it sadly lacks yet the support of the principle of consideration for others.

M. B.—We know nothing of the Office in question, except as advertisers.

ARMY MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—By the last mail we learn, amongst other things, that an increase of pay to the officers of the army medical department is contemplated. It is to be hoped, if this prove true, that definite arrangements will be made with the India Office to prevent the absorption of any extra pay that may be granted to us by Royal Warrant.

The Warrant of April 1st, 1867, was received as a great boon by the then assistant-surgeons, who consoled themselves on an increase of 2*s.* 6*d.* a day after each five years of service in lieu of rapid promotion to field officers' rank; but this proved a delusion to those who were destined to serve in India. Surgeons, as a rule, come out to this country after one year's service at home, and remain for five years, return home for two or three years, and again come out for another four or five years. It will be thus seen that they are in India *one* year after the first increase of 2*s.* 6*d.*, and *three* or *four* after the second increase after ten years' service; but it is scarcely credible that these officers do not receive the increase of pay granted to them by Royal Warrant, and the pay of surgeons of the British army in India stands unaltered since before the Warrant of 1867 was published. As our pay in India exists, it is calculated on a wrong basis, and at a rate of exchange utterly ruinous, considering the depreciation in value of the rupee. It appears that the Warrant of 1858 is the basis of calculation, and in turning English money into rupees, half-a-crown is valued at a rupee; whereas, in remitting money for family purposes, the Government value their rupee at 1*s.* 10½*d.* The following table will serve to show more clearly my meaning:

Amount now paid to surgeons of over ten years' service. English pay calculated at 2s. 6d. = 1 rupee.	r.	a.	*Pay calculated from Royal Warrant of* 1867. 2*s.* = 1 *rupee.*	r.	a.
English pay at 13*s.* a day ...	158	0	English pay at 15*s.* a day ...	225	0
Full batta...	182	10	Full batta...	182	10
Gratuity	36	0	Gratuity	36	0
Tentage	75	0	Tentage	75	0
Consolidated pay of a surgeon of over ten years' service, monthly...	451	10	Amount a surgeon of over ten years' service considers himself entitled to monthly	518	10

It will be clearly seen that the difference between these two calculations is 67 rupees, which, calculated at its nominal rate of 2*s.* to the rupee, is £6 14*s.* a month, or £80 8*s.* a year—a very large sum to lose by the rate of exchange; but when remitted home at 1*s.* 10½*d.*, utterly ruinous to a married man trying to educate his children.

In explanation of the table, the "full batta" and "tentage" are old institutions granted, according to rank, to all officers in lieu of quarters, coal, candle, and servants, and to enable officers at all times to possess a tent, and be thus independent of the State. The "gratuity" is an additional allowance to enable junior officers to maintain existence. It is plainly shown that the Royal Warrant of 1867 is not acted on in India, and it becomes a question, Are we entitled to ask, each of us, for the amount deducted from our wages since April 1st, 1867? And who is responsible for this breach of faith? Perhaps this may be one cause for discontent in our department.

Your obedient servant,

India, August 21st, 1875. HOPE.

MEDICAL MEN AND QUACK MEDICINES.

A CORRESPONDENT forwards us two remarkable testimonials to the virtues of "Burnet's Female Pills" by Liverpool practitioners. If these testimonials, respectively by Mr. A. Maclellan and Mr. John De Courcy Young, are not genuine, the sooner they are disowned the better.

TAVISTOCK DISPENSARY.

To the Editor of THE LANCET.

SIR,—The paragraph in your journal of September 25th is wrong as far as I am concerned. In consequence of the interference of the dispenser, Dr. Crighton resigned; but on September 27th (yesterday) withdrew his resignation.

Yours truly,

Tavistock, Sept. 28th, 1875. R. SLEMAN.

SUPERANNUATION ALLOWANCES.

Union Surgeon.—The law of 1864 is that no officer shall be entitled to such allowance on the ground of age who shall not have completed the full age of sixty years, and shall not have served as an officer of some union or parish for twenty years at least. The Act of 1870, "the Medical Officers' Superannuation Act," secured the application of the earlier law to medical men, *though they might not have devoted their entire time to the service of the parish.* No allowance can be obtained under this Act on the ground of permanent infirmity of mind or body, unless a Poor-law inspector, or some person authorised in that behalf by the Local Government Board, shall have first certified that in his opinion such officer has by reason of such infirmity become incapable of performing the duties of his office with efficiency. As to the amount, it is not to exceed in any case two-thirds of his salary at the time of resigning; but in the estimation of this may be included certain extras, excluding such as he earns in his character of medical practitioner.

Dr. Moore and *Mr. Johnson* (Lancaster) are thanked.

FOOT-AND-MOUTH DISEASE.

To the Editor of THE LANCET.

SIR,—Many of the statements contained in the article on "Foot-and-Mouth Disease" in THE LANCET of September 18th may be disputed, especially those relating to the veterinary department of this country, whose usefulness is only limited by its narrow proportions. It is constituted of one chief, a gentleman of acknowledged talent in his profession, and of a very extended experience, supported by a well-selected staff of scientific, intelligent, and energetic veterinary surgeons, supplemented by a very respectable class of men whose lives have been spent among cattle &c. The intuitive knowledge of these men as regards the detection of the earliest symptoms of disease renders them extremely valuable as auxiliaries to the veterinary inspectors, to whom all suspicious cases are referred. The police, from their perfect organisation in carrying out the correspondence, and enforcing compliance with the orders of the department, combine to form a supervising power in circumscribing the extension of contagious diseases it would be difficult to improve upon were it less contracted in its dimensions.

Veterinary inspection at the port must be admitted to be the best security that the importing country can have, next to its own quarantine. Such inspection must also gradually recoil on the *fons et origo mali*, which is not so amply provided for as it might and ought to be; but, however complete the arrangements for inspection at the source, they would not do away with the absolute necessity for a repetition of it at the point of embarkation.

"Unfairness and oppression" rarely result from the operation of the provisions of the Act in this country; whilst cases of reckless neglect and attempts at blockade running, owing to the vigilance of the department, seldom fail to meet the retribution they so justly merit. My experience during the last three years of the surveillance of the Irish departmental veterinary surgeons in the conduct of their inspectorial duties at the North-wall and other ports in this country convinces me of the enormous utility of their services in preventing the shipment of cattle &c. presenting even the faintest signs of contagious disease, much less those which might be more deeply invaded by infectious lung mischief, many of which would otherwise inevitably be shipped. Their presence has further a very beneficial effect in deterring the unscrupulous in attempting to ship doubtful cases. Too great stress is laid upon the idea "that Irish cattle are a fertile source of the affection"; nor, considering the great numbers exported, is it surprising that after all their travels by road and rail on *both* shores, with the intervening sea passage, many of the outbreaks should be ascribed to their movements, though I am firmly of opinion that the emigrating cattle frequently contract it after their departure from these shores. As the existence of the incubative stage or the presence of the contagium can never be certainly discovered or repressed if known, and as the malady is generally tractable, sure to run a definite course, it appears to me that we may be content to accept such practicable methods regarding its limitation as tend to reduce its dangers to their minimum, and that there is no necessity to resort to German models for the conservation of our public health on the one hand, or the facilitation of our cattle commerce on the other; nor need we pale at the phantom of imaginary contamination, lest in our attempts to clear this Scylla we fall into the Charybdis of a paralysed supply, with the evils which such a deficiency would entail upon our carnivorous population.

As the result of a personal inquiry at the Office of the Veterinary Department of the Privy Council, I beg to append the following information as to the extent of its correspondence, the comparative existence, spread, and diminution of "foot-and-mouth" disease during last week, ending Sept. 19th, 1875:—

Number of communications received by post during week ending Sept. 19th, 1875	3205
Ditto ditto ditto Sept. 12th ...	3828
Number of fresh outbreaks reported during week ending Sept. 19th, 1875	1983
Ditto ditto ditto Sept. 12th ...	2224

Showing a decrease of 241.

N.B.—Outbreaks do not mean individual cases, but farms, lands, premises, or places on which the disease has appeared within the periods set forth, on which many animals became affected. By returns sent in to-day (Sept. 20th, 1875) the disease is reported to have disappeared off 674 farms &c. The above figures show no indisposition on the part of "farmers and others" to screen the existence of the disease.

Each of the communications alluded to contained from six to ten enclosures or separate documents. The number of envelopes sent out to the post on Saturday was upwards of 1490, each of which contained from one to fifty papers; two cabs were filled from floor to roof by the volume of correspondence &c., which amounted to close on 12 cwt. So much for "a few returns, which, even if reliable, are of very little value," according to your contributor.

As an army veterinary surgeon, I may be acquitted of any other motives than public weal and a love of fair play in raising my voice in defence of a very useful but obviously insufficiently appreciated section of my professional brethren, whose position seals their lips, but whose usefulness will stand the test of public criticism.

I am, Sir, yours obediently,

THOMAS PATON,

Dublin, Sept. 23rd, 1875. Veterinary Surgeon, Army Service Corps.

A "VERY IMPRUDENT" ACT.

A LINEN-WEAVER at Leeds was charged at the Police Court of that town on the 24th ult. with what the magistrate, in pronouncing sentence, described as a "very imprudent act." It appeared in evidence that this weaver had had a son who was unfortunately attacked with small-pox, and who died on the 9th of September. It may here be parenthetically remarked that this weaver has, or rather had, five children, not one of whom has been vaccinated, and all of whom have had small-pox; but this is not the "imprudent act" of which he was found guilty. While the son above-mentioned was suffering from small-pox, the weaver, like a dutiful father, sat up with the patient at night, but went to his work every day in the same clothes. He was engaged in a linen factory, where he had charge of a room in which sixty girls used to work. The result of the importation of small-pox infection into this factory-room was that at the time of the hearing of the case ten or twelve of the girls were stricken with the disease, and three had already died. The weaver was charged under the 126th section of the Public Health Act, 1875, with having exposed, without previous disinfection, clothing which had been exposed to the infection of a dangerous disorder. He was convicted, and sentenced to pay a fine of £5, or, in default, to undergo two months' imprisonment. This was the offence which the Leeds magistrate described as a "very imprudent act." We must confess that we should have been inclined to describe it in much stronger terms. Perhaps, however, under the circumstances, we ought to feel satisfied that the new Public Health Act contains a clause under which a magistrate, who regards so lightly such an offence as that of which the Leeds weaver was guilty, feels bound to convict.

Podagra.—It can be obtained at Walters', 16, Moorgate-street.

"CHEAP DOCTORS."

To the Editor of THE LANCET.

SIR,—In a note on the dispensary system as applied in private practice, you write disparagingly thereof, and remark that, although there be no written law to the contrary, an unwritten code forbids the system. Something, Sir, is to be said in behalf of the private dispensary system.

A medical man, living in a poor part of town, has to find his account amongst a population ill able to bear *any* charge for medicines and attendance in sickness. The cost of living has certainly not been cheapened of late, nor the struggle for existence eased. A man earns, say 30*s.* per week. Suppose he has four children, not a large family; two have scarlet fever, in one followed by dropsy. What charge for visits and medicines would make this illness unfelt in that family? At 1*s.* 6*d.* a visit, including medicines, the man would be wellnigh ruined, and even at 1*s.* per visit greatly reduced, and that at a time when extras may have to be supplied. Let the "bread-winner" himself be stricken down, and even the 2*s.* 6*d.* or 3*s.* per week of the private dispensary system cannot be paid, and the aid of the parish must be sought, to the impairment of that spirit of independence that political economists seek to keep up, and to the probable increase of the rates.

Again, few medical men who are not poor at the commencement of their career "start" in a working-class neighbourhood, and ready money is to those who do everything, and all losses are avoided. But it is not because a gentleman is poor that he is ignorant, and unable to treat the majority of cases that come under his care cheaply. The cost of most drugs is not overmuch when a few of the more costly are left out, and it is not every case that requires the latest discovered drug or combination of drugs. A large mass of patients is properly treated for syphilis with mercury, mineral acids, or iodide of potassium. Hundreds of cases require only some preparation of iron; and ammonia, the alkalies, bitters, and nux vomica are not expensive; whereas the dearer drugs, as quinine, opium (which latter will go a very long way), are not very ruinous in cost, even when freely prescribed, and I do not believe anyone would fail to give them when required. I have experience of the practice of several gentlemen with dispensaries, and I know they all use quinine largely.

Sir, I hesitated to open an establishment of the kind in question when my receipts were but £5 per week, and when I had to do a lot of work, for part of which I lost the payment. This amount was inclusive of about seventy cases of midwifery in the year. Since I have opened a dispensary I take £16 per week, and have no losses and no midwifery. My health is better, my circumstances are better, and I have more leisure, and I do not plead guilty to having neglected the interests of my patients. Nor can I in any way admit that I have hurt the pockets of my neighbouring practitioners; for I am surrounded with dispensaries, which were in existence before my advent here.

Sir, that unwritten law of which you wrote allows free hospitals and dispensaries, where it is sometimes said highly educated gentlemen of good position give advice for nothing to people who, though they can pay a fee, do not; and if a medical man of the higher grade may work for nothing, and have for patients a class which can afford to pay, why may not another work for a small fee, which is as much as the sick can spare, and which in the aggregate well pays the recipient? Yours obediently,

London, September, 1875. S.

Dr. R. T. H. Bartley.—We are not competent to give a legal opinion on the question; but it seems to us that Dr. Bartley's title is too special and distinctive to be complained of by the proprietors of Visiting Lists. Rather should they be obliged to him for a valuable addendum and advertisement.

PERIOD OF UTERO-GESTATION.

To the Editor of THE LANCET.

SIR,—The following brief notes of a case which has just occurred in my practice may interest statisticians.

T. B——, in her twenty-seventh year, began to menstruate on Christmas day last. On the 3rd January following she was seduced by her lover, only one intimacy taking place. Labour began on the 23rd inst. about 8 P.M., and was completed by short forceps this day, 25th inst., at 11 A.M. Duration of pregnancy consequently 265 days.

I am, Sir, yours &c.,
Old Kent-road, Sept. 25th, 1875. W. T. GREENE, M.A., M.B., &c.

COLD-WATER INJECTIONS IN TYPHOID.

THE use of cold water in therapeutics, and especially in typhoid, is one of much present interest. Dr. Foltz, of Lyons, has lately published in *Lyon Médical* a valuable series of papers, containing the results of his employment of cold-water injections in typhoid fever. He states that they exert a general and local action. The local action consists in a cooling sensation, accompanied by intestinal contractions. The general action produces slackening of the pulse, marked diminution of temperature, and quietude of the nervous system. It abates thirst, excites the appetite, and increases the secretions. The cooling, sedative, and tonic action is about the same with all injections under 38° (centigrade); but it is so much more intense and durable as the injection is colder, more abundant, and more frequently repeated. As to the therapeutical indications of cold-water injections, Dr. Foltz thinks they are very numerous. Through their local action they are of use in affections of the abdomen, and through their general action in febrile maladies. They are, therefore, doubly necessary in typhoid fever, for the treatment of which they constitute the chief remedy.

Mr. Douglas Lithgow's letter shall be kept in mind.

SCARLET FEVER AT HURDSFIELD (MACCLESFIELD).

To the Editor of THE LANCET.

SIR,—I cannot help thinking that Mr. Leighton Kesteven's letter is calculated to do more harm than good to the cause he advocates.

Hitherto, although much has been written relative to the outbreak of scarlet fever in Hurdsfield, I have refrained from entering into any controversy about it. I still decline to do so; but Mr. Kesteven's letter contains so many inaccuracies that, in justice to you, Mr. Editor, to the Macclesfield Sanitary Committee, and myself, I feel I ought to correct them.

Mr. Kesteven states that when the vicar of Hurdsfield refused to close the school, the scholars at which were suffering severely from scarlet fever, he was acting on the advice of certain medical men, who had signed a memorial to that effect. This is not the case. On the morning of Friday, Aug. 20th, the vicar positively refused to accede to the request of the Sanitary Committee to close his school, and stated that under any circumstances he should keep it open, unless ordered to close by the Education Department. Nothing was then said about any medical memorial; neither was this memorial signed until the following day, when it was generally known throughout the town that the vicar had placed himself in opposition to the sanitary authority. Thus it is evident that the vicar's refusal was not based on the medical memorial, but that he afterwards obtained the signatures to help his case. As Mr. Kesteven places so much stress on the memorial in question, he should in fairness have stated that the signatures of the medical men were obtained solely on the *ex-parte* statements of the vicar, and that, although among other things the memorial certified that the school was in "a good sanitary condition," several of those who appended their names thereto never troubled themselves to ascertain the truth of that statement by a personal examination of the premises; indeed, one medical gentleman has since admitted to me that he never read the memorial before signing it! Against signatures obtained in such a loose way as this, I think we may fairly place your statement, Mr. Editor, which has been endorsed by the whole sanitary press:—"There is not a shadow of doubt that, however originated, the infant school was the focus of disease, and the intercourse of so many children at this infected spot was a source of danger to the inhabitants."

It is not a fact that the sanitary inspector gave such a report on the state of the school as described by Mr. Kesteven, or any other report on the subject. He inspected the school with me, and his opinion was similar to mine as to the choked-up drain, the defective ashpit, and filthy state of the closets, which had never been limewashed since their erection, and were, without exception, the dirtiest I have ever seen attached to a public school. After, however, the vicar had refused to close the school, and after the closets had been limewashed, and the drain laid open, a member of a local firm of surveyors examined and reported on the sanitary condition of the school. The value of a report obtained after the chief causes of complaint had been removed is easily estimated.

The use of the name of Mr. Jas. Bland, and the assumption of a closer degree of relationship than really exists between us, are unwarranted. I may state that Mr. J. Bland, who is a practitioner of forty years' standing, and a J.P., and was for twenty years the medical officer of health, has never interfered in the slightest degree between the sanitary authority and the Rev. Mr. Handcock *ab initio ad finem.*

Mr. Kesteven commences his letter by stating that the vicar of Hurdsfield refused to close his school when requested by the medical officer of health, and concludes with the remarkable statement that no one "could ever assert truthfully" that the vicar "ever did, or could, want to obstruct" the work of the medical officer. The fact is well known that the vicar did obstruct the work of the sanitary authority and their officer of health by refusing to close his school when scarlet fever was epidemic among his scholars. Your correspondent, in attempting to justify the vicar's refusal, admits the "obstruction," and his letter also proves—if it proves anything—that Mr. Handcock was aided and abetted in his resistance to the powers which be by those who ought to have known better.

There are other inaccuracies in your correspondent's letter, which, did your space and my time permit, I might refute; but I will conclude by expressing a hope that when next Mr. Leighton Kesteven addresses your columns, he will previously ascertain the truth of any statements he may make, and that he will not use his pen in attempting to justify ill-advised resistance to the requirements of a sanitary authority.

I am, Sir, your obedient servant,
GEORGE BLAND,
Medical Officer of Health for the Borough of Macclesfield.
Macclesfield, Sept. 27th, 1875.

PHILADELPHIAN DEGREES.

Dr. Walker is thanked for the interesting copy of correspondence which he sends us. He will see that the subject is noticed elsewhere.

Mr. Thomas Q. Couch.—A master is not responsible for payment for medical attendance on his servant in the absence of a special undertaking.

A Query.

A correspondent wishes to know whether traction after death, such as might be used in dragging a body out of a river, could lengthen it *three* inches. Two men disappear; the height of one is 5 ft. 6 in., of the other about 5 ft. 7 in. or 5 ft. 7½ in. A body is found, so much decomposed as to be unrecognisable, under suspicious circumstances, hands tied &c.; but the body is 5 ft. 9 in. in the recumbent position.

Mr. Boughton Kyngdon. — The advertisement is a disgraceful one. The individual is probably insensible to criticism or reproof.

Medical Certificates in Cases of Deaths from Violence.

To the Editor of The Lancet.

Sir,—The author of the article in your impression of Sept. 18th, headed "Medical Certificates in Cases of Deaths from Violence," appears to have written it without bearing in mind two sections of the Births and Deaths Registration Act, 1874. By section 20 it is enacted that—"In case of the death of any person who has been attended during his last illness by a registered medical practitioner, that practitioner shall sign and give to some person required by this Act to give information concerning the death a certificate stating to the best of his knowledge and belief the cause of death." And by section 39 it is enacted that—"Every person who refuses or who fails without reasonable cause to give or send any certificate in accordance with the provisions of the Act is liable to a penalty not exceeding forty shillings."

There is no law in existence which requires a medical man to report to a coroner the death of a patient, occurring under whatever circumstances it may. Had Mr. Lodge's certificate been taken to the registrar of deaths before the man's body was buried that official would have brought the case under the notice of the coroner, who would then, in all probability, have been spared much of the unpleasant duty which has since devolved upon him.

I cannot see that a medical man in giving a certificate of the cause of death of any patient whom he may have attended in his last illness "usurps the functions of a coroner," or that he exceeds his duty in the slightest degree. The course pursued by Mr. Lodge was, I think, strictly in accordance with the last Registration Act, and consequently did not merit the censure of the coroner. Your obedient servant,

Westbury-upon-Trym, Bristol, Sept. 20th, 1875. Henry Ormerod.

⁂ Our correspondent is mistaken in assuming that our article was written without bearing in mind the two sections of the Births and Deaths Registration Act, 1874, to which he refers in his letter. By section 20, a registered medical practitioner is certainly bound to give a medical certificate showing the cause of death of any person whom he has attended in his last illness. The Act, however, does not specify any particular time when the certificate is to be given, and certainly contains no provision which would prevent a medical practitioner declining to give a certificate in any case in which, in his opinion, an inquest ought to be held, *until* the case has been referred to the coroner. This is the course which we recommended, and believe to be highly desirable on public as well as professional grounds. Our correspondent will excuse us if we express our belief that in nine cases out of ten the medical attendant would be infinitely better qualified than the registrar to decide whether a case was a fit and proper one to be referred to the coroner; and it would be highly objectionable if medical practitioners were called upon to give certificates in cases of violence that would be the subject of inquests, when the certificates would become useless documents.—Ed. L.

Mr. P. B. Giles, Jun.—1. Wilde, Hœning, Ercolani.—2. Dr. Barnes in Medico-Chirurgical Transactions, 1851 to 1853.—3. Sir James Y. Simpson's work.

Palliative Treatment of Ulcers.

To the Editor of The Lancet.

Sir,—Will you kindly publish the following case, not of curative, but of quite successful palliative treatment of a large, open, offensive cancer.

Pain and the exceeding fetor make the last months of patients who cannot recover most miserable. The lotions &c. usually employed prove troublesome, and of very incomplete effect. It may be that this very simple method is known and practised; but as yet I have not met with any sufficient record of such a case. It has not been suggested by any consulting man my patient has seen; she herself and her friends feeling so marked and so happy a change deserve to be made known to all. The open sore, some nine inches in diameter, is well but most gently washed by a tepid stream of Condy's fluid and water, using syphon and jug. Then it is moistened all over with four or five drachms of a carefully filtered solution of two to three and a half grains of acetate of morphia in fine spray, so used that none leaks off. It is then covered, nothing intervening, with very finely sifted, perfectly dry animal charcoal, the sore being completely covered and concealed. This is done with a pepper or flour dredge or an indiarubber bottle. Over this is placed the very softest light covering, and the patient is clothed so as to be with her friends. Before this was done the smell was very offensive and sickening, not only throughout the room, but in the near passages. Now it can scarcely be perceived at three or four inches from the breast. The use of morphia (Battley's) &c. internally was more distressing than the pain. Now the pain is infrequent and comparatively very bearable; the morphia being used in no other way than by spray.

I am, Sir, your obedient servant,

Forest Hill, S.E., Sept. 21st, 1875. W. Rendle.

The late Dr. Wardrop.

To the Editor of The Lancet.

Sir,—Can any of your readers kindly inform me of the existence and present residence of any *near* relative of the late Dr. Wardrop, of Charles-street, St. James's? My query has especial reference to any constant visitor or resident (even old housekeeper or butler), who might be well acquainted with his excellent collection of pictures. Dr. W., as is generally known in the profession, died Feb. 13th, 1869, aged 87.

I am, Sir, your faithful servant,

Sept. 29th, 1875. An Old Subscriber.

Old Reader.—An author may certainly give a few copies of a professional work on a special subject to a few non-professional friends and well-wishers without being chargeable with advertising himself or acting unprofessionally. Of course there are subjects so special and scales of distribution so large as would make such a procedure open to criticism.

Carbolic Acid.—If our correspondent will refer to our back numbers, he will find numerous letters on the subject of pruritus ani.

Coroners and Doctors.

To the Editor of The Lancet.

Sir,—Your correspondent of the 18th inst., writing under the head of Coroners' Inquests, has brought forward a subject upon which many of your readers would like some advice. The following case occurred in my practice.

On the morning of the 12th August I was sent for to attend M. N——, and requested to hurry, as the child had been born some time. On arrival I found the woman had been delivered of a living child; the pulse was scarcely perceptible; skin cold and clammy—in fact, the patient was dying. The bed was saturated with blood, and in one corner of the room I saw a vessel containing about a gallon of blood clots. On examination per vaginam, I found the funis broken from the placenta, with a small piece of the latter attached; the uterus was large and flabby, filled with clots; and a remarkably tough placenta, which was almost entirely adherent. I removed the after-birth and clots without the least hæmorrhage, gave ergot and stimulants; but there was not the least action of the uterus until the woman died, about half an hour after I arrived. There was a nurse and a midwife in attendance, and from the latter I gained the following particulars. She had seen the patient on the previous day, when she recommended medical advice, knowing that her former labours were very difficult. The woman, however, did not like to have a doctor, nor did she retain the midwife. The latter was, however, sent for in the middle of the night, and on arrival found the child born, great hæmorrhage, and the funis broken. She immediately insisted on medical aid being sent for, thinking that the patient would perhaps not live until it was procured. The nurse in attendance states that "she slept on the bed with the patient, as the pains had left her; she awoke suddenly, found the child born, and the funis broken. Alarmed at the hæmorrhage, she sent for the midwife." After this I refused a certificate; but when the coroner heard the above facts, he said "there was no need whatever for an inquest; such a thing would be quite unusual." I then filled in a certificate, stating particulars to the registrar; but I heard no more of the matter.

Now, Sir, might not this woman's death be brought about by the nurse not attending to her in time, and then trying to detach the placenta by pulling at the funis, and in consequence breaking it? In a case like this (and I fear they occur too frequently) what is a medical man to do when the coroner refuses to hold an inquiry?

I am, Sir, your obedient servant,

September, 1875. An Inquirer.

The Body of Jeremy Bentham.

A correspondent wishes to know where the body of Jeremy Bentham now lies.

Convalescent Homes, and one of their Gross Abuses.

To the Editor of The Lancet.

Sir,—I was lately applied to by a young man (who is in a Benefit Society), asking if I would kindly give him a certificate for the Convalescent Home of Mrs. Ruster, of Dover. He had not been under my treatment, nor under the treatment of any other medical man, nor had he been suffering from any illness whatever; his only complaint being want of a holiday at the seaside. He could get a recommendation from the Rev. Mr. Bromfield, of the parish of St. Mary-the-Less; this would be available for a month. However, as he had but a week's holiday, he only intended to remain for that period in the Home. Of course I need scarcely add that I refused him a certificate. He seemed very much annoyed, and said he was down at the same Home last summer, under precisely similar circumstances, for a period of a fortnight, obtaining his letter from the same source. He stated that there were several people there under similar circumstances. He also added that they dined with the female *convalescents*, and went out for nice rambles and walks with them, and that he enjoyed his holiday very much indeed. He paid a reduced railway fare of 5*s.* for the return journey, and was fed and lodged in the Home for 9*s.* a week.

Need we wonder at the great difficulty there is in finding room for our poor convalescents when their beds are occupied by holiday-makers.

I am, Sir, your obedient servant,

September, 1875. Albert S. Morton.

"Penetrating Power of Salt."

To the Editor of The Lancet.

Sir,—Having read in your last issue "A. B.'s" account of the penetrating power of salt, I determined to try the experiment for myself. I accordingly left a strong solution of salt and water standing all night in a ware jug, *glazed both inside and out*, and in the morning found the outside of the jug quite *free* from the crystals of common salt—in fact, just as it was overnight. Had your correspondent's jug a crack in it? I should like to ask—1st. Supposing "A. B.'s" experiment to elucidate a physical fact, is this quality of the salt properly called its *penetrating power?* 2ndly. Can we take the "great power of penetration" of a drug as a means of estimating its "value as a local remedy in cases of gout, rheumatism, &c."?

I am, Sir, yours respectfully,

September, 1875. Sal Non-permeans.

Strychnia Poisoning.

To the Editor of The Lancet.

Sir,—I have just read Mr. Lammiman's letter in your last number about a case of strychnia poisoning.

I once took an overdose of liq. strychniæ, which would certainly have been fatal, as the spasms were becoming more frequent and stronger, one lifting me in the air and throwing me prostrate on the ground. I immediately took chloral hydrate in two half-drachm doses, one within ten minutes of the other. I began instantly to get well, each dose having great effect.

Yours &c.,

September, 1875. M.R.C.S.

CHEAP DOCTORS.

THE following is an illustration of what we said last week on [this subject. Could the Colleges, whose titles Mr. Timothy advertises in such an objectionable way, not remonstrate with him?

"Dalkeith-street, Barrow-in-Furness.

"INDEPENDENT DISPENSARY.—This dispensary was opened by Mr. Timothy, L.R.C.P. Lond., M.R.C.S. Eng., L.M.R.C.S., and L.S.A., to afford medical and surgical relief to the working classes. Attendance every morning from nine to twelve, and every evening from six until nine. To meet the working expenses, the charge for each patient will be sixpence. The charge includes advice, medicine, and every other requisite. A visit to any dispensary patient within the town will be one shilling."

Dr. W. A. Jamieson.—1. Mr. S. Jeffery, Superintendent, Kew Gardens.—2. About 2*s.* 6*d.*

SOFT CHANCRES.

To the Editor of THE LANCET.

SIR,—I have been very much struck with the following sentences in Mr. Hutchinson's lecture on the above subject, as reported in your impression of the 18th inst., and cannot help directing attention to them. "Thus," says Mr. Hutchinson, "if you could to-day exterminate soft sores, and destroy all the secretions capable of producing them by contagion, you must expect in a few weeks again to find them reproduced. If, on the other hand, you could destroy all hard chancres, and all the specific germs of syphilis, there would be no reproduction of the disease." Are we to infer from these assertions that Mr. Hutchinson is a believer in *the special creation of a syphilitic virus?* I am &c.,

September, 1875. D. CAMPBELL BLACK.

COMBINED SANITARY DISTRICTS.

A CORRESPONDENT writes to us as follows:—

"Allow me to correct an error in your last week's issue. The combined sanitary district of Peterborough, Whittlesea, &c., is not a new district, it being formed at the commencement, two years ago. The salary was then £800, and Huntingdon and Godmanchester were in it; but these places (and I believe others) have seceded, and one has joined, so reducing the salary to £639. The appointment was made last May for this year; but was, I am told, informal, inasmuch as it was made without advertising the vacancy."

COMMUNICATIONS not noticed in the current number will receive attention in our issue of the ensuing week.

COMMUNICATIONS, LETTERS, &c., have been received from — Dr. R. Barnes, London; Dr. Lockhart Robertson; Dr. Sedgwick Saunders, London; Mr. Fairlie Clarke, London; Dr. Adam, Liverpool; Mr. R. Smith, Winchester; Mr. Sleman; Dr. Gill, Clapham; Mr. Price, London; Dr. Payne, London; Mr. Watkins, Worcester; Mr. Murray, London; Dr. Wiltshire, London; Mr. Tait, Birmingham; Dr. Walker, Anerley; Dr. Sutcliffe, Torrington; Mr. Reeves, London; Dr. Cripps, Cirencester; Dr. Faber, Freudenstadt; Dr. G. Introductory Address
ON
SCIENCE IN SURGERY.

Delivered at the Owens College (Manchester Royal) School of Medicine, October 4th, 1875,

BY EDWARD LUND, F.R.C.S.,
PROFESSOR OF SURGERY, OWENS COLLEGE.

MR. PRINCIPAL AND GENTLEMEN,—The command which I have received to deliver to-day the first lecture of the present winter session is one which I obey with feelings alike of anxiety and pleasure: of anxiety, lest in the remarks I have to offer I may fail to do justice to the important topics to which I must allude, and lest I may fail to inspire those who are to listen to me with the interest which the subjects deserve; and of pleasure, when I consider how it has come to pass that one who not many years ago entered Manchester as a stranger, with no claims of birth, of interest, or of kinship, should have found himself gradually raised, as the simple reward of hard work, and through the kind consideration of his professional brethren, to the proud position which I now occupy—that of joint lecturer on surgery with my friend Professor Southam, and a member of the Senate of the Owens College.

And here I am reminded that I appear in this lecture-theatre to-day as one of the few surviving representatives of the old Pine-street School of Medicine and Surgery. I was appointed demonstrator of anatomy in that school at the beginning of the session 1850–51. It was at that time that my present colleague, Professor Southam, seeing, with several other earnest and active men, that lethargy and inactivity were likely to overshadow in some degree the well-earned reputation of the school, conceived the idea that by establishing a second institution for the teaching of medicine and surgery in this city fresh energy might be excited and fresh interest be awakened in the ever-widening field of medical science. In this opinion the promoters of the new school were not mistaken, for from 1851 may be dated a certain revival in Manchester of the character and range of professional education. Medical education in Manchester since 1851 has steadily advanced; it has now reached its acme of method and opportunity (though still capable of indefinite expansion) in the splendid appointments and in the brilliant inducements to professional study afforded by the establishment of a medical department of the College in which we are now assembled.

In thus glancing at the past history of our school, how sorely do we miss on this occasion that which would have been a living commentary upon its best era—the benevolent, the honest, the cheerful face of our late dear friend, Professor Wm. Smith. How shall we estimate the loss we have sustained? And who, shall it be said, can fill as he did the vacant place? I knew him well—intimately, if I may be allowed to say so. I knew the inner spirit of the man. I knew (at least in regard to most public matters) the earnest motives which actuated him in all he did, and in all he tried to do, for the advancement of our medical school. In private life also, away from professional associations, I had frequent companionship with him, and in many ways I am still reaping the benefit of his many acts of generous kindness to me, in sickness and in health, the recollection of which can never pass away. Professor William Smith was indeed the student's friend; and this, happily, his pupils thoroughly understood and as thoroughly acknowledged, for there was not a lecturer in the school who was received by his class at the commencement of a session, and who was parted with at its close, with warmer or more sincere proofs of appreciation, and it may be doubted whether in this respect any lecturer can ever hope for an equal tribute. Not one of the lecturing staff could compete with Professor Smith in the marvellous way in which he held his audience upon his lips. Everyone who listened was enchanted by the vigour and the rapidity of his descriptions, by his wondrous memory, and the distinctness and the accuracy of his illustrations. He would continue for forty or fifty minutes, until, at the close of the lecture, every student felt that some new fact had been made more clear, some truth more positive, the only regret on his mind being that the lesson so ably imparted should have come to an end.

No one was more exact and constant in his appointments, either here in the College or elsewhere, until at length failing health seemed to say, "Thy work is nearly done." We have good reason to believe that this gentle hint, by Nature so kindly given, was not lost on him, for many things have come to light since his decease which show that this warning voice was not unheard. He knew full well, as he toiled on in the daily round of duty, that life's silver cord might soon be broken. He told me more than a year before his death, that his only ambition, as far as his school duties were concerned, was to give just one course of lectures in these new buildings, and that he then would take his leave. And really it would almost seem as if this great wish of his heart had met with its accomplishment, for we all know the sad incidents of his death, and I need not here dwell upon them. The circumstances connected with it remind me of an anecdote told of a foreign army, in which a private soldier, beloved by his fellows, had perished in the fight, completing some gallant act of duty with consummate bravery. After his death, when peace had been proclaimed, to give perpetuity to the esteem in which the fallen brave one had been held, one of his comrades was told off daily from the ranks, when the roll was called, the name of the dead soldier being retained upon it, as if his spirit hovered around his regiment to stimulate others to emulate his bright example, and the reply was to be "Died in action." So have I thought, gentlemen, if when we delight ourselves in recalling the many familiar names of those who have done good service in our midst, and the roll of past worthies shall be read over, we might appropriately place against the name of Professor Wm. Smith these words: "Died at his work." For so in truth he died, and those who knew him well can, I imagine, easily supply all the outlines of the picture of the last sad scene, in which, still working to do good, he must have bestowed on his little patient one of those bright smiles with which he was wont to light up and strengthen many a sad heart; and the very last act in which he was engaged was an act of kindness. "Ah! he was a man; I knew him well, and take him all in all, we shall not look upon his like again."

The science, as well as the practical art, of medicine—the *ars medendi*, the art of cure—falls by common consent into two great sections. To the physician are allotted all those deviations from health which depend purely upon functional derangement, or from that same condition, so far as it is traceable to structural change in the organs affected, if, indeed, it ever does occur without such change; and to the surgeon are assigned all those alterations of form which, either as hypertrophies or as new growths (arising from whatever cause they may, local or general, including the effects of injury, damaging the actual arrangement of structure) require mechanical treatment, either for removal, for relief, or for cure. But the mechanical surgeon is only half a surgeon, if the restoration to health in every case which is committed to his care is only to be sought in operative interference. If surgery is to be defined as operative medicine, many cases would be lost through the *nimia diligentia chirurgi*. In surgery, as in medicine, viewed as separate branches of a single art, scientific success can only be secured by placing each case under the most favourable conditions of health, so as at all times to give nature the first chance in her attempts to repair the injury, or absorb the growth. And it would almost seem as if, in the practice of surgical as contrasted with what are called medical cases, the surgeon has far more evident proof of the wondrous reparative powers of nature, when left alone, than medicine proper can ever boast of. While we think with wonderment on the creative wisdom by which the growth of animals is effected; whilst we delight to note in our anatomical explorations the exquisite manner in which every part is planned, so as to adapt itself to its requirements, and to harmonise with the parts around it, so that in the general contour of every portion of the body there shall be no loss of space and no redundancy, strength being given where most required; here elasticity, and there resistance, all designed beforehand in well-balanced proportions;—while we contemplate these things in the healthy body, and observe how the whole machinery is preserved intact until some external force injures it for a time, we shall find that there has been lying in quiet reserve all the while—it may be for years, even for those of a long life—a certain energy ever on the alert, and ever ready to step forward at once to repair the breach, and to replace in their proper order the broken walls.

This reparative power, this *vis medicatrix naturæ*, this power of repair, is declared throughout nature, and becomes especially conspicuous in the practice of surgery. No sooner, in a severe injury, has the system recovered from the nervous shock which pain and fright must occasion, than, if we note carefully, we shall observe, as action recommences, the early stages of repair; the faintness, even to loss of consciousness, which is present, is in itself, by diminishing the current of the circulation, a means of arresting the still further loss of blood, the very *pabulum vitæ* through whose agency we know the direct means of repair have chiefly to come. Then, after a time, in cases of special local injury, we have what surgeons call inflammatory changes. But the surgeon looks on these very differently from the physician; he knows that inflammation, after surgical injury, if it can only be controlled,—if it can be held back as a restive horse in its early and less rapid movements, will tend to secure a readhesion of the parts, and it would almost seem, as far as some of the less vital structures are concerned, the formation of a new tissue. Thus it is that the surgeon looks on only to admire the ready way in which repair is effected, provided always,—and here it is that his skill shows out most boldly,—that the conditions and aids to nature's efforts are made favourable. It is useless to talk simply of the power which nature possesses to repair a fracture in the hard tissue of bone after its forcible division by injury, and by which power it may be as neatly united as the scar in a cut finger. Such union may occur, and it has so occurred, where fortunately the corresponding points of the broken bone have been adjusted so as to be again absolutely opposite to each other, and there retained without the slightest disturbance for many days. But the great difficulty consists in this: around the broken bones there must be lacerated muscles, or displaced and extended tendons. These will pull the portions of bone still further apart, causing more or less deformity, and thus acting in direct opposition or direct antagonism to nature's efforts. What can the surgeon do here? It is not for him to insult nature by trying to stimulate or hasten her efforts by any artificial means, but simply to attempt—and the more successful he may be the more certain the result—to place the broken pieces of bone, particle by particle, exactly opposite to each other, as nearly as possible at the same spot as they occupied before the severance of their tissues; and this being done, to retain them there—to do all that is popularly termed "setting" a fracture, but which might be more accurately expressed as replacing the fractured bones; and then by means of the thousand devices, entirely mechanical in their nature, which surgery employs — the splints, the plasters, the weights, the bandages — keeping the broken portions of bone accurately adjusted. All the rest is nature's work, and happy is it for us when we do not thwart her, for she is ever equal to her task.

In practical surgery two things have to be had regard to—our means of investigation and our modes of treatment; and fortunately in both of these matters great improvements have been made in modern times. As means of investigating the exact nature and seats of disease or injury, we have now in our hands instruments of precision which those who trod before us the path of surgery would have gloried to have seen. What would Hunter, or Cooper, or Tyrrell, or Key have given for the extended vision which is afforded by the modern microscope, or for the practical and invaluable evidences which are supplied by the ophthalmoscope, the laryngoscope, or the delicate instruments for lithotrity perfected by the genius of Sir Henry Thompson? Until comparatively recent times, in cases of confirmed blindness, it might be said neither the patient nor the surgeon could see; the patient could not see, and the surgeon could not discern the cause of his loss of sight. A thousand attempts were made to record the subjective symptoms related by the patient, but the objective symptoms, as observed by the surgeon, were worse than useless. If, in the days of Milton, with "Wisdom at one entrance quite shut out" by "so thick a drop serene," the surgeon had possessed such an instrument as this, who can tell with what "cathedral music" the poet would have immortalised the man who, aided by the ophthalmoscope, could have devised a remedy for his great affliction?

Yet, in the employment of these instruments of precision—these fresh means of extended observation—we must ever bear in mind that it is not so much the objects which we see or feel as the clinical lesson which their presence teaches. This can only be learned by practice, by comparison of repeated observations, or by the systematic teaching of others. Mere observation without interpretation, so to speak, of the meaning of a phenomenon, is of little service. This brings me to speak of the modes of treatment in scientific surgery. Here, however, my illustrations will begin very early, as the first I shall give you is taken from the condition of the unborn child. There is a congenital deformity well known to surgeons, and which we call cleft palate,—a condition of things distinguished by imperfect growth of bone, whereby a cleft or fissured space is left in the centre of the roof of the mouth, exposing in this direction the cavities of the nostrils. The surgeon is often called upon to try to remedy this deformity after birth; but it may seem paradoxical to ask him to suggest a cure, or, more properly, the means of its prevention before birth. Yet even this may be rendered possible. By the study of comparative anatomy we learn that the portions of the bone wanting in cases of this deformity are two small ossific centres, which in man correspond to two distinct bones intended to carry the large front teeth or tusks in some of the lower animals, and their growth is completed only in the human subject near the close of intra-uterine life; therefore, if at this period the mother's health should fail in its nutritive powers, the child may be imperfectly developed in this particular part of its skeleton. It is the failure of bone-growth at a special period of fœtal life which is the very essence of this deformity.

It was observed in the collection of animals of the Zoological Society of London that a certain lioness, always breeding with the same lion, gave birth on several occasions to lion cubs with this particular deformity, and the probable cause was for a time a matter of doubt, such deformity being rare among the lower animals. As soon as it was noted that this animal, in common with the other carnivora, was fed on lean meat cut off from the bone, it seemed probable that the deficiency of growth might be due to the absence of bone-food in the mother at a time when she most needed it, she having given up, it might be said, all she could spare from her own system for the completion of the growth of her young. The idea was acted upon the next time the lioness was in cub. She was fed freely with meat still attached to the bone, and the bones were left in the cage to be gnawed by the animal at pleasure. The result was that in the next litter all the cubs were perfect, and the hindrance was cancelled: that which an insufficient observation in the human subject would have attributed to the effects of fright or an undue influence on the imagination, was shown to be referable to imperfect nourishment, and failure in the powers of growth entirely dependent on external conditions.

May we not read a lesson from this? May we not even say, are we not reminded, that possibly, in the progress of gestation in the human female, the food, composed, among other things, too exclusively of wheaten flour, as compared with the oatmeal porridge of our northern friends, and other errors of dietetics, may sometimes deprive the mother of the elements needful for complete fœtal ossification, and engender these deformities?

Take another example, also from the young, from the newly-born—the conditions by which the deformity of clubfoot are brought about, and see how far our reasonings on the subject must affect our treatment. Clubfoot is a deformity which generally, not invariably, dates from birth. In it the muscles of the leg which control the movements of the various component parts of the foot contract unequally, and in such a way as either to raise the heel inordinately, so as to place the foot almost in a line with the leg instead of at an angle, and there to fix it; or one set of muscles twists or pulls the foot inwards, and even casts it backwards; or the opposite muscles draw the foot very much outwards, which is the rarer form. Now, the question at issue is this: there are two sets of muscles, the one helping to invert the foot, the other to evert it. In any given case, say of inverted foot, the *talipes varus*, or perhaps the *equino-varus* of authors, which are the offending muscles? Which are they which by their continued action, unbalanced by their antagonists, are to be blamed for the deformity? Are the inverting muscles too strong, and are their tendons too short? Or are they really not excessive in their action, and is it the evertors which, either from imperfect growth, from temporary paralysis, or from special cause, are too weak to resist the inward direction of the foot, the deformity being thus commenced and perpetuated? Those who argue that the invertors are too strong and too short, proceed to correct this assumed condition by dividing the tendons, diminishing for a time the contracting power of the muscles. Then the foot can be bent over to its natural position with comparative ease, and it is thought that a great triumph has been gained. But the opponents of this line of treatment say, It is true that in this way to the eye of a casual observer the cure is instantaneous and complete, but this temporary gain is more than counterbalanced by the fact that, having brought down the standard of force of one set of muscles to that of the other weaker muscles, the movements of the foot are likely to be permanently weakened on both sides, and a dangling, flail-like motion of the foot in the act of walking will be a very possible consequence. The invertors of the foot were not the muscles at fault; they were but contracting with a force of normal intensity; it is to the innate weakness of the evertors (their antagonisers) that attention should be directed. Do not, therefore, divide the tendons on the inside, but employ a gradual traction of the foot by suitable mechanical appliances on the outside, so that with some elastic force of low intensity, acting constantly in the line of the tendons of the everting muscles, more strength may be given them, and in this way at last they will tire out the spasmodic action of the inverting muscles by slowly—very slowly it may be, but yet very surely, if the system be well carried out—drawing the foot into its natural position in relation to the leg, gradually bringing up the tractile power of the congenitally weaker muscles to the standard of their antagonisers. The surgeon rarely fails to relieve such deformities by the line of treatment I have detailed, if it be commenced early enough, for it is founded on the strictest principles of inductive reasoning.

Permit me to give two other illustrations of the advances made in scientific surgery, and I will then pass on to other subjects. One of these is the opinion now expressed in what may be called, for the sake of distinction, the doctrine of tension in surgical cases, and the other is the possible organisation of the blood-clot, in open wounds, under certain conditions. Recent observations have shown that tension, which is but another form of pressure, in so far as it interferes with the capillary circulation in any part, is frequently the cause of effusion of fluid, or of the continued secretion of fluid, where as a product of inflammatory action, or from any other cause, it has been formed already. Take, by way of example, an enlarged bursa containing fluid near a joint. Let us suppose it is the bursa lying beneath the skin near the tendon of the patella at the knee-joint, which is much exposed to pressure in the act of kneeling, and is styled, when enlarged, the "housemaid's knee." It is here placed by nature like a water-cushion, to diminish the effects of pressure and friction in the movements of the joint. In a healthy state its sides are nearly in contact, and the cavity between them would not hold more than a drachm of fluid. In the case which we are supposing, the cavity, let us imagine, has in eight weeks become so tightly distended that it contains an ounce of fluid, and it is hardly possible—indeed, it is highly improbable, that these eight drachms of fluid were secreted in equal times during the eight weeks—that is, at the rate of one drachm per week; but much more likely is it that, if we had the means of exact measurement, we should find the secretion had gone on in an ever-increasing ratio—say half a drachm per week in the commencement, against perhaps two or three times that quantity at a later period. And so we may conclude the formation of fluid would go on with augmented rapidity until the containing structures had been stretched to the very utmost; then most certainly would inflammatory action arise, as happens in a few rare cases of this sort, the final progress and termination being very similar to that of a chronic abscess left entirely to nature. But as yet we will assume that there is no active inflammation. The sac of the bursa is simply distended by fluid, to an excessive degree, by passive effusion.

Now let us see what lines of treatment are open to us in the management of such a case. I will name the heroic or the most extreme measure first. It would be possible, but not good practice, to cut down upon the bag of fluid, carefully to detach it all round from its connexion with other tissues, and, without in any way piercing the walls, to lift it entirely out of the bed or space in which it lies, and thus to remove it altogether. We will assume that the patient would recover, but of course she would no longer have a loose pliable skin over the knee, but an unyielding scar at the spot where previously we had had our water-cushion. Another plan would be this: either by simply piercing the bag of fluid at some part, or by cutting into it so as to fully expose its cavity and let in the air, to set up inflammation, by which we should have the formation of adhesive material, the walls of the sac would be glued together, and the cavity obliterated; or we might carry the inflammation into the stage of suppuration, in which, pus being formed, the vessels of the part will undergo some change of condition, and after a time they will cease to secrete the glairy, watery fluid they had done; the lining membrane of the sac is destroyed, and, in fact, the bursa is gone, and our water-cushion exists no longer.

But "there is yet a third course open to us," as a once eminent statesman would have said, and that is simply to open the bag of fluid and let out its contents. This at once takes off the pressure on its internal surface, by the continuance of which the circulation and the secretion had been so disarranged as to be the cause, in reality, of that loss of balance between secretion and absorption which is the true origin of the accumulation of the fluid or dropsy of the sac. If such an incision be made, if the balance of healthy pressure be thus restored and all be kept in this state, if none of the products of inflammation are allowed to manifest themselves, quietly day by day the cavity of the bursa will shrink back to its normal dimensions, a small opening, still left patulous to the very last, will finally close, and the bursa will once more resume its functions, filled only with just enough secretion—perhaps a mere *halitus*—to allow its walls, when pressed upon, to slide over each other without friction or pain. But this result can only be secured by some line of treatment whereby inflammation and its consequences can be with certainty avoided.

Next as to the organisation of clot in surgical injury. It has been long known to surgeons, and admitted ever since the days of Hunter, that clot, or an effusion of coagulated blood, may become organised, and may even have vessels travelling through its substance after a certain interval of time, and that gradually, by some mysterious process of vitality, this clot may be converted into cellular tissue, which is, as it were, a packing or connective tissue to all the others. But then until very recently this change in the blood-clot was very rarely, if ever, to be observed, since it never occurred in open wounds, for reasons which I will explain; and in closed wounds—those in which, although the tissues had been broken down and disintegrated, there was no exposure of the parts so injured to the air—as, for instance, in a simple fracture, where the skin is entire, as compared with a compound fracture, where the skin is broken,—but every structure around the ends of the bones was broken up, torn, and separated. Much blood was effused, but all being securely protected from the air by the interposition of the skin, we were unable to discover by ocular inspection, except in some cases after death, at a distance of time from the date of injury, that the blood so effused had become organised; while in a compound fracture, where all had been exposed to atmospheric contamination, no such result was possible or attainable. But it is to the glory and triumph of antiseptic surgery that it has shown, not only the possibility, but the actual and visible evidences, of the frequent occurrence of the organisation of the blood-clot, where wounds such as I have described are successfully treated on those fixed principles of antiseptic surgery now so often described, and yet, alas! so little appreciated by the majority of surgeons.

The two conditions to which I am now referring are perfectly attainable. The open bursa shall not inflame, and the effused clot of blood lying open to the eye in the superficial recesses of a wound shall not putrefy—shall not even liquefy and dissolve away, but it shall remain solid and become organised, helping to fill up in bulk the loss of substance, the destruction of which at the time of the injury had occasioned the escape of blood from the blood-vessels.

The subject is too vast and too much beset with difficulties to be dealt with, otherwise than by contemplating its results, in a lecture such as the present. I must just remark, however, that it is only when the excretions from the bursa, or from the wound on which we seek to note the changes in the blood, are kept absolutely harmless and free from putridity, that the results I have detailed are obtainable. We know, therefore, when we may hope to meet with them; we know equally well when we can never attain them. It is not by waiting until rancidity or putridity in the excretions of a wound has just commenced, and then trying to arrest these changes and so to hope for the wished-for result; it is then too late, far too late. It is by anticipating, not by antagonising, that such changes can be averted. Surgeons forget, or perhaps they have never seriously thought of the fact, that the antiseptics which we employ, at least those now generally in use, are valueless to arrest putrefaction when once it has commenced. If the term so employed, and which is in everyone's mouth, "anti-septic" (against septicity, against putrefaction), could have been written *ante*, and read *ante-septic* (before septicity, in the order of time), and if this simple principle could have been thoroughly inculcated into the professional mind, it would have been of immense value, and would have taught us the necessity of beginning our efforts to prevent putridity at the very earliest moment after the air could touch some divided structure of the body, with which nature never intended it to come into direct contact; and if this idea were generally and systematically recognised, an immense advance would be made towards a more cordial reception of the leading principles of our practice in this mode of treating wounds.

That these principles must at last be received and adopted in the practice of surgery no one can doubt who has watched the progress which they have already made and are still making amongst operating surgeons. The day cannot be far distant—if it be not already very near at hand—in which the great founder of this system, on which he has worked with energy and earnestness, and yet with the modesty of true genius, shall witness the best of all rewards—its universal adoption. It is a system, gentlemen, which surely in the abstract must commend itself to your attention; but, like all other novelties, in theory or practice, it has had to pass through its stages of development. At first it was said, "It is not true; such results cannot be obtained; it is a deceit, a delusion, and a snare." Then, as it moved on to its second stage of growth, it was said, "It is not new; if that be all you try for, we can attain corresponding results, with equal success, by far simpler means." And now at last, happily, it is entering on the third phase of existence: its former opponents are watching its results and acknowledging its utility; and a remark which Prof. Lister once addressed to me in a letter in the early days of his labours in this direction—almost prophetic in its nature—seems now to be on the verge of fulfilment. "Don't be disheartened," he said; "go on in your work, and you will be rewarded; for the time must come when a surgeon will be ashamed to own that he cannot dress a wound antiseptically."

Thus, gentlemen, I think I have shown you that in the practice of surgery, as a division of general medicine, there is much on which to exercise the mind in its higher faculties, not only of patient and thoughtful observation, but of inductive reasoning. If the subjects we seek to investigate have thus far been obscure, how much more should we welcome the entrance of the smallest ray of the light of truth, which will always shine out most brightly in the darkness of error.

To the new students who are here to-day, to the freshmen of our year, and to those who have not yet quite determined to join us in our search for knowledge, I would say a few words which I trust may confirm the wavering, and make them more decided in their choice, whatever that may be. "One volunteer is worth two pressed men" is a well-known adage, and when a student comes to us with a resolution to study medicine with interest, and because he feels a natural taste for the subjects it embraces, he will be ten times more likely to achieve success, than if he were forced into the work by the pressure of circumstances over which he has no immediate control. But, above all things, let me warn you not to follow our profession for the sake of acquiring wealth, for most assuredly if you do so you will debase a good cause, and make shipwreck of your fortunes. It must be done for higher objects than this if it is to be done at all, and with any prospect of success. In this busy world of ours the mind must have field for action. It holds within it, from its very nature, that restlessness which will drive us to some form of work, be it bad or be it good. The idle man is not really inactive; what he does is profitless, except for evil, but you may rest assured he is still at work—planning schemes of chance, or devising new forms of deceptive pleasure. His thoughts can never rest—move on he must, and we know, alas! in what pitiable obscurity his life must end. But the man of industry—the child of toil, has, with all his apparent wants, fountains of true pleasure which are unknown to others. We are all working-men, we have all our task to accomplish, and to try to do it well is in itself a source of endless comfort.

Let me then urge you, gentlemen, in the future of your life, to select for your occupation some acknowledged work which shall bring good to others. It may be in public life, where, actuated by high principles, you set yourself to promote some great social change, or to avert some widespread disaster. And where could you find, if such principles as these are to guide you in your selection, a more worthy employment for life than that of trying to heal the sick and to help the injured? In the pursuit of medicine you must abandon self, you must take in with your mental eye a far wider circle, and you must look for your reward, not in the accumulation of wealth, but in social status and conscious power.

Thanks to the energetic teaching of Professor Morrison Watson, and the untiring industry of his earnest colleague, Mr. Perrin, the success which has attended our presentments at the primary college examination in London during last year have been all that we could desire, for we are second for all England, including the metropolitan and provincial schools; and in the second or pass examination for the diploma of membership of the College of Surgeons of England, the students educated at the Owens College (Manchester Royal) School of Medicine have been first in the pass list, showing that our students have well profited by the many advantages presented to them in the surgical instruction at the Royal School of Medicine and at the Manchester Royal Infirmary. Long may this be so, gentlemen! But we must not forget that there are examinations, and there are examinations. This past success—I may say this recent success—must not lead us to be over-confident in the future. We must strive to retain our proud position, and I am quite sure I only express the feelings of my colleagues, as well as my own, when I say that we look to the future with an anxiety equal to your own, for your success will be ours. We are bound to you by an earnest desire for your advancement, and every fresh honour gained by you for our school will be always valued by us.

One very important addition has been made to our school life during the recess, to which I must now refer, for, by mutual arrangement most creditable to both parties engaged, the very valuable and extensive library of the medical section of the Manchester Royal Institution has been handed over to the trustees of this College under certain special conditions, and will very shortly form an integral part of the contents of this building in an educational point of view. In accordance with certain rules which have been framed with much care, the students of this school will have the privilege of using some portions of this library, but the greater part will only be accessible to the members of the Society, who must necessarily be qualified medical men. We trust, gentlemen, that the inducements to acquire a taste for literary pursuits in our profession will be excited in no slight degree amongst our students by the opportunities thus presented to them, and that it will become a rule amongst them, as soon as they obtain their qualifications, to become full members of the Medical Society, of which they will have already enjoyed a portion of the privileges; and in this way we hope the existence of an extensive library within this building may be one among other means of binding you in closer bonds to the spot where your education was commenced, and that you may look back in after life, with increasing pleasure, to this as your *alma mater*—I would almost call it, anatomically, your *pia mater*.

Medicine in all its branches is now pushed onwards at so many points, and day by day so many new facts are brought to light and old ones newly examined, that it behoves us all—students as we ever must be to the end of our career—to take advantage of every means by which we may keep ourselves abreast of the passing stream, and float on the tide of progress; for not to advance is to recede. May you all look back with pleasure to student days, not as we are apt to account all that are passed as the most agreeable of our life, but as days of profitable associations, enduring friendships, and industrious habits; and may you let your motto ever be—"*Aspice finem*,"—look to the end. Do not attach too much importance to present success; it will be bought too dearly if purchased by the slightest breach of inter-professional duty,—by any temporary advantage which circumstances may throw in your way over your fellow-workers; therefore, so try at all times to follow your path in life that, as the end draws near, there may shine out in the past at least a few cheering spots like oases in the desert, which you may remember with pleasure—some generous acts performed, some well-marked proofs of conquered selfishness.

It is in our intercourse with each other in professional life, especially with those who are travelling along the same course, and perhaps at the same speed as ourselves, that we have need to be prepared not quickly to take offence, as far as criticisms on our conduct are concerned, and not too readily to criticise the conduct of others. "He is the best surgeon who has made the fewest mistakes" is a saying which will often teach the operator himself humility, or lead him to be less ready to censure others; and if, perchance, gentlemen,—and such occurrences will take place, even where your proceedings are ruled by the most honourable motives—injustice has been done you by someone who ought to have inquired more closely before he helped to spread some groundless report, alike injurious to your honour and success, do not, as some would do when so aggrieved, make some solemn vow, registered with unbending determination, that with such a man no further intercourse shall ever be had, but try rather to call to mind the remark once made on a public character unjustly accused of dishonesty—"That man's reputation is not worth much who cannot afford to outlive scandal." If this should fail, and if, as time rolls on, it would still seem that the incubus of an unjust charge could never be shaken off, make one more effort to gain the comfort of an approving conscience;—do not persecute your accuser, but pass it by, and remember it is one of the attributes of a great mind to know how to forgive an injury.

Thus it is, gentlemen, that I hope in the future practice of your profession you may be able to press on, from year to year, in a sphere of increasing usefulness, carrying with you blessings by which you may be able to encourage the weak and comfort the afflicted, and to aid in restoring to health those bowed down by injury or struggling with disease; so that at the end of a well-spent life, reviewing its receding epochs till you call back your student days—perhaps this very day in which I now address you—you may apply with hope the words of the poet, where he says:

> "Time was when thou, a naked, new-born child,
> Alone didst weep when all around thee smiled;
> So live that, sinking to thy last long sleep,
> Thou only smile while all around thee weep!"

Disease among Pigs in Ireland.—Our contemporary, the *Veterinarian*, commenting on the fatal malady which has broken out among the pigs in the South of Ireland, especially in the district around Waterford, inclines to the opinion that the pigs are suffering from typhoid or enteric fever. This disease is by no means uncommon in Ireland, and, when once it has gained a footing in a district, is sure to spread and assume a fatal character for want of all sanitary regulations on the part of the owners of the animals. Typhoid fever in pigs, which has long been known to be contagious, is now also proved by the recent experiments to be infectious in the ordinary acceptation of the term.

CHARING-CROSS HOSPITAL.

MR. FAIRLIE CLARKE'S INTRODUCTORY ADDRESS.

After alluding to the recent death of Dr. Headland, to the improvements which had been made in the school premises, and the enlargement of the hospital, Mr. Fairlie Clarke went on to address himself specially to the different classes of medical students. He said that he was particularly anxious to welcome those who were joining the school for the first time that day, and to give them some encouragement and counsel. He congratulated them on entering the medical profession at such an auspicious moment, when medical science was making such rapid advances. He mentioned the subjects which would chiefly occupy their attention during the next six months, and gave them some advice as to the best way of laying out their time. Mr. Clarke said: "You are just taking the important step whereby you pass from boyhood to manhood; and it is not too much to say that everything depends on the use which you make of the time that is under your own control. Temptation rarely comes during busy working hours; it is in his leisure time that a man is either made or marred. Make up your minds firmly as to your proper line of conduct, and, having done so, follow your own course with decision and resolution. It is oftentimes more really manly to dare to say "No" than it is to fall in with the suggestions of those who may be older than yourself in years or academical standing." He recommended a certain amount of reserve in the first instance in the choice of friends, but assured them that they would by-and-by find among their fellow-students not a few whom they might well be happy to gain as life-long friends. He pointed out that at Charing-cross a diligent student can always obtain one practical appointment after another as long as he remains *in statu pupillari*; whilst at the larger hospitals this is frequently impossible, and the students are often obliged to enter on the practice of their profession furnished with little more than the information that can be obtained from lectures and books.

To the second-year's students, who would now be expected to visit the wards regularly, Mr. Fairlie Clarke pointed out the great interest of in-patient practice, both on account of the severity of the cases treated and the more personal relations which are established between the doctor and his patients; and these personal relations cannot fail to draw out our sympathies. He said: "We seem to tread on sacred ground while we accompany the hopeless sufferer to the very verge of this world, to that bourne whence no traveller returns, and this invests our profession with an interest and a solemnity entirely its own." He specially urged upon those students who held in-patient appointments the cultivation of a considerate manner in going about their work, saying that this was quite compatible with a keen interest in the study of disease, and would be likely to win the confidence of the patients.

To the senior students Mr. Fairlie Clarke said: "To you, more than to any group among us, is the welfare of this medical school committed. I do not under-estimate the influence of your teachers, but more a great deal than what we can do is what you can do. Our influence is exercised only occasionally, yours is exercised constantly. We are placed here in authority, and we are all of us less disposed to accept the advice of those set over us than we are that of our equals. It is scarcely too much to say that what you are the younger students will be. Suffer me, therefore, to impress upon you one or two pieces of advice. Remember the weight that your example must of necessity have, and let no idle word thoughtlessly spoken sully the purity of the young minds that are joining us for the first time to-day. Let no word or act of yours cast ridicule on the principles that have been learnt at a mother's knee and fostered under a father's roof. Let nothing induce you to suppose that idleness and dissipation are manly. There is no true manliness but in the diligent discharge of duty. If you, senior students, act in the spirit I have endeavoured to indicate, then hard work and good order will be general among the whole body of students.

"I often think, as I come within sight of Charing-cross, that the very situation of our hospital is a constant reminder to us to do our duty faithfully and in a high-minded way. We are here surrounded by monuments of national grandeur. To say nothing of Charing-cross as a great commercial centre, we are here close to the Houses of Parliament, to the chief offices of State, and to the abodes of Royalty. The improvements that are going on in our immediate neighbourhood are beautifying it, and making it more worthy to be, as it is, the great centre whence the influence of England goes forth over the whole world. Often when I have been coming to my work here I have bethought me of that bright morning in October, 1805, when the English fleet bore down on the united squadrons of France and Spain off Cape Trafalgar. It scarcely needs the inscription on the Nelson monument to remind us of the watchword, now become an English proverb, which was then signalled from the masthead of the *Victory*, and which stimulated all to do their duty so gallantly. Or I have bethought me of the conqueror of Scinde, Sir Charles Napier, the very soul of honour and rectitude, so independent in his bearing towards his equals, so free from all time-serving and tuft-hunting, so just and considerate to those under his command, so kind and humane to those who were in trouble or distress. Or I have bethought me of Havelock, the very ideal of a soldier, an officer, and a Christian, doing his work diligently and cheerfully, notwithstanding straitened circumstances and professional disappointments. It was not the stimulus of early success, nor the favour of princes, nor any lower motive, which carried him through the disappointing years that formed so large a portion of his military career. It was nothing short of a strong Christian principle which sustained him.

"The monuments of these great men have been erected in our immediate neighbourhood, not merely to do honour to individuals, but also to keep alive in the breasts of each succeeding generation the virtues for which they were distinguished. And if there is any class of the community who are likely to be influenced by the recollection of their noble deeds, it is surely the young men of England, our educated youth, before whom life is just opening. Duty, honour, and the fear of God—these were the mainsprings in the characters of the three heroes to whom I have alluded. If you, students of Charing-cross Hospital, are fired with the same principles, we need have no fears for the success of the session that opens to-day. It cannot fail to be a happy and a prosperous one; and we may leave in your hands the interests of this medical school, feeling confident that they are safe in your keeping."

LONDON HOSPITAL.

INTRODUCTORY LECTURE BY DR. BATHURST WOODMAN.

After some prefatory remarks on the mingled feelings with which such a meeting of old and new students must be regarded, the lecturer remarked that the history of eminent medical men refutes the common notion that the study of medicine has a tendency to create sceptics. Such is not the case. Celsus, the medical writer, and Celsus who was answered by Origen, were separated by a whole century. Nor is it true that the medicine of antiquity was all a farrago of nonsense or a collection of quaint conceits. A careful study of the writings of Hippocrates and other ancient writers disproves this, just as the metrical precepts of the School of Salerno, or a view of the fine lavatory of Gloucester Cathedral, disproves the popular lecturer's notion that people never washed at all in the Middle Ages.

Vivisection was next alluded to, and, whilst its abuses and the needless barbarities at Alfort (twenty years ago) were condemned *in toto*, the necessity for experiments upon animals was insisted upon, and justified from the imperfections of our art, from the examples of the wisest and best of its professors in the past, and because human life and human happiness are so infinitely more valuable than the lives of animals. If those who oppose all such experiments could witness the scenes of horror often met with in our hospitals and in private practice, their opposition would be less keen. The late Sir Robert Peel's life would in all likelihood have been saved had chloroform been more known when he met with his accident, and such substances as chloroform must first be tested upon animals. We must look to a healthy public opinion to regulate these experiments, rather than to any sensational cries or legal enactments. Dr. Woodman next insisted on the necessity of students earnestly resolving to train themselves for the practice of their profession. "It is no longer possible to learn our art from the pages of any manual, however excellent, or from any one teacher, however eminent. Every day increases our difficulties in the diagnosis of disease. For example, a few years ago only wall-papers of a peculiar grass-green colour contained arsenic in any appreciable quantity, or so as to be dangerous. Some people think so now. But what is the fact? Since the general introduction of aniline colours, no paper, however sober its hue, can be trusted as free from arsenic until it has been carefully analysed." Numerous examples were given of lead and other poisons in articles of food, in cosmetics, and in clothing; and even in our medicines there are often dangerous adulterations. Hence the necessity that a medical man should have at least some general acquaintance with chemistry, and also with arts and manufactures. A part of this, at least, should be gained before coming to a medical school. Parents and guardians were earnestly appealed to to give their sons or wards, if about to enter the medical profession, a thorough grounding, not only in English, but in Greek, Latin, and elementary mathematics. From his experience as a teacher and as an examiner, as one who had helped some hundreds to gain diplomas, not from one examining body alone, but from almost every examining board in the three kingdoms, he confidently affirmed that nine-tenths of the rejections and failures arose from defective preliminary education. When a student came to the hospital and medical school, he ought not to be forced to work at any grammars or lexicons except those of disease; the wards of the hospital should be his chief books. Let not the student be too proud to learn from everybody or anybody. All his teachers will not be equally eloquent or equally skilful, but much may be learnt from the practice of the very worst physician or surgeon; much may be learnt from his fellow-students; even a fisherman or a ploughman may often be well-read in the book of nature. Great men like Linnæus and Agassiz knew this well, and acted upon it. If willing to be taught, the stores of knowledge in the London Hospital, now one of the largest in the metropolis, were shown to be almost inexhaustible. "If the difficulties of your profession are increased and are increasing, so are the facilities for learning. Here you will meet with every possible aid from the staff." The lecturer showed that the London Hospital had never lagged behind in the march of medical progress. Its staff and its alumni had not only availed themselves of every scientific improvement, but had largely added to the general store. They were truly practical men; but their practicality was not that of ignorance, but of science. Students were encouraged to work for the prizes which are offered by the London Hospital Medical College. This year some nine principal prizes, whose money-value alone is over £300, are to be given away. He defended the system of prizes. It had once been abandoned at the London Hospital; but the results were not encouraging. He earnestly begged the students not to waste their first year, as too many had done. Let them never forget that the chief aim and end of medicine was to cure and to relieve. Lamartine had well said: "La médecine guérit quelquefois, soulage souvent, console toujours." Let their aim be to multiply the cures. "Depend upon it the public will never tolerate us, or pay us fees, merely to stand by the bedsides of those they love as mere scientific observers, or a sort of Greek chorus. For although there be times when the highest wisdom is to hold our hand lest we rudely quench the struggling spark of life, it far more often happens that we can do much either to cure or relieve pain. But to do so we must learn all we can, and must ever be learning."

Examples of successful treatment on scientific principles were given. Hopes were held out that even cancer and tubercle—those malevolent twins—might in time be conquered and disarmed by careful studies and experiments upon animals. The influence of fashion in medicine was deprecated; and the lecturer concluded by warning the students against the baneful influences of dogmatic scepticism, which is often as injurious to the progress of the healing art as it is to the spiritual and eternal welfare of the man.

MIDDLESEX HOSPITAL.

INTRODUCTORY ADDRESS BY MR. B. THOMPSON LOWNE.

The lecturer (who spoke without notes) said—"We must admit that theory has much to do both with the advancement and retardation of science, and at the very outset of your career as medical students, you are brought face to face with the rival claims of facts and theories. We must bear in mind that, although false theories have often retarded progress, no progress is made in science except when theories are used as instruments of research. Indeed, I do not know how any sharp line can be drawn between a fact and a true theory. A fact is the interpretation of certain external phenomena by our minds, for of the phenomena themselves we can know nothing, we only know their effect on us; so a theory is the interpretation of a more complex set of phenomena by the same instrument. Misled, then, by false views and theories, and unguided by true ones, men made no progress, but rather retrograded, until the modern science of medicine took its birth in the master-mind of Sydenham, who was truly a second Hippocrates. But I need hardly remind you changes had occurred in the world during this lapse of time; men's minds had been freed by changes in their religious tenets, culminating in the work of Luther. The greatest, perhaps, of man's inventions—the printing press—was actively engaged in reproducing the writings of the Ancients, and in rendering the workings of men's minds permanent, so that they should defy even the ravages of time. Columbus and Galileo had lived, and their discoveries were vast experimental verifications—the touchstone of inductive philosophy. Pliny, centuries before Columbus, believed the earth to be a globe, because he knew that the water that forms the dewdrop assumes the spherical form. Copernicus and Kepler had reasoned out the laws which govern the movements of the heavenly bodies; yet, even to a thinker like Lord Bacon, theories of spirals and vortices with the earth for their centre seemed more probable, and the great Chancellor never grasped the fact that Galileo had set the matter at rest for ever when he demonstrated the moons of Jupiter and the phases of Venus. Many men, however, learned to recognise the principles of the true reasoning which led to truth from the false and *a priori* deductions which led to no good results. To return, however, to our own science. Vesalius, even against the powerful antagonism of Fallopius, had shaken the authority of Galen in anatomy, and Harvey had discovered the circulation of the blood by the experimental methods. Chemistry was an infant science during the lifetime of Sydenham, and owed its existence to the minds of Boyle and Beecher. The time was propitious—the bright dawn of science had commenced, and it wanted only a master-mind to make medicine a most noble study. Sydenham laid its foundations on the work of Hippocrates, and Boerhaave took up the work where Sydenham left it. From that day to this great names and great workers have never been wanting in the medical world—men with free enlightened minds seeking laboriously for truth and finding it. * * *

"Knowing that your scientific work, through no fault of your own, must now begin *de novo*, I would urge you to lose no opportunity, but to use the best efforts to make up lost time."

UNIVERSITY COLLEGE.

PROFESSOR CORFIELD'S INTRODUCTORY ADDRESS.

After saying that most medical addresses nowadays treated of sanitary matters, and that therefore the audience would not be surprised if his did, Dr. Corfield went on to point out the importance of sanitary science as a part of the education of every medical man. "As it is not, like most of the subjects in the medical curriculum, made a compulsory subject of study for medical students, most of them not unnaturally think that it is not necessary for them to learn it, and so they pass it by; nay, more, their object in coming to a medical school is, they conceive, to learn to cure disease, and it may seem to them that it is not their business to try to prevent disease. Let us consider this for a moment. Medical men know more of diseases than other people do; they not only know much about the remedies that have to be employed, but they of necessity know much about the ways in which diseases spread, and much, therefore, about the ways in which they may be prevented. Are they not, then, bound to use their knowledge for the good of mankind? Are they not bound to make that knowledge as perfect as they can? And have not medical men always recognised this from the time of Hippocrates to the present day? Hear what our own Sir William Jenner says:—'No one acquainted with the present state of the science and art of medicine will for a moment question that to prevent disease is its first and most important aim.' Weigh well these words of your great master and mine, and place beside them those of Sir William Gull: 'It is enough for us that diseases prevail to stimulate our best efforts for their prevention, without our asking a question beyond;' words worthy to be remembered by every medical student. And have not medical men been the discoverers of the methods at present known for the prevention of disease? Look at the discovery of vaccination, the preventive of small-pox, the most terrible and fatal plague that ever appeared on the face of the earth. Who made that discovery? Who have strenuously advocated its advantages in spite of ignorant and often interested opposition? Who have proved that the ravages of small-pox are lessened, and that the disease might be exterminated by means of it? Who but those the hope of whose gains is gone by its practice? And why is small-pox not exterminated? It is because ignorance and prejudice prevail, and prevent the efficient carrying out of the Vaccination Laws, and prevent the general adoption of revaccination. Germany has set us an example here, for in March of last year a law was passed making the vaccination of infants, and also the revaccination of children of riper years, compulsory throughout the whole of the German Empire. If this law is strictly enforced, we shall see the practical extermination of small-pox in that great empire, and then perhaps other countries may follow the example. You may all help in hastening the arrival of the day when a similar law will be passed in this country, and it is your duty to do so—a duty you owe to the memory of Jenner.

"Let us look at some other diseases. Where are the black death, the sweating sickness, and the plague? Where is scurvy, that decimator of the armies and navies of the world? They are where typhus fever will soon be, where enteric will be some day, where every disease which we conquer will be sooner or later—they are, practically speaking, exterminated. Look at the discovery, by medical men of our own day, of the difference between the conditions under which typhus and typhoid fevers spread; or look at the discovery, by an old University College man, Dr. G. Buchanan, of the connexion between phthisis—our great endemic plague—and dampness of the soil below the houses; and you will see that medical men are finding out the ways of preventing disease.

"All medical men are liable to be asked their opinion nowadays upon the great sanitary questions of the day, and are expected to be generally acquainted with the works carried on, both engineering and architectural, for the well-being of the community; they are especially frequently required to give an opinion about the sanitary condition of internal household structures; but it is especially necessary that they should be acquainted with the means for preventing the spread of contagious fevers. Medical men, out of deference to the wishes of their patients, very frequently do not report cases of infectious fevers to the sanitary authority, and so it is essential that they should know how to prevent these diseases from spreading. What we really want is a law to make it compulsory on medical men to report these cases to the medical officer of health, and then patients would have no choice in the matter. Fortunately nature does much more to check the spread of these diseases than we can do; for if a man took scarlet fever in the first week of the year, and gave it to two persons in the second week, and each of these to two others in the third week, and there were nothing to prevent this going on at the same rate, everybody giving it to two persons (and only to two) in the week after that in which he got it himself, which is not at all an unreasonable rate, the people who would have had scarlet fever at the end of the year would be sufficient to populate four million five hundred thousand worlds, with a thousand millions of people each! So you see it is fortunate that something stops the spread of infectious fevers.

"Medical men are also bound to study hygiene because it affords important aids to cure, fresh air, exercise, and a proper diet being often more important to a patient than drugs. Remember the words of Rollet, of Lyons, 'Medicine cures individuals, hygiene saves the masses,' and the maxim of Hippocrates, 'Nature is the healer of diseases.'" Dr. Corfield then referred to the remarkable evidence given by Dr. Fergusson of the degeneracy of the factory population, and his opinion that want of milk was the chief reason for it; he said that the only way to get milk enough was by the utilisation of the sewage of towns, and that the solution of the sewage question would be the prevention of the degeneracy of the population of our large towns. "But it is especially essential that those who may become medical officers of health should be thoroughly acquainted with hygiene; they are consulted on all possible matters relating to the public health, and they must be thoroughly posted in all sanitary matters. Degrees and diplomas are now granted for State Medicine, as it is termed, and the facilities for instruction in the various branches have now been greatly increased in the College by the establishment of a practical course under the charge of Professor Williamson and myself, and a new laboratory for hygienic analyses is being fitted up and will soon be ready for use."

WESTMINSTER HOSPITAL.

INTRODUCTORY ADDRESS BY MR. RICHARD DAVY.

The speaker said that he disapproved *in toto* of introductory addresses, but, at the request of the Medical Council, conformed to custom. Both students and teacher preferred a day's pheasant shooting to hearing or giving an "introductory." As a surgeon, he should cut down his sermon from one hour to fifteen minutes, and his successor might still further reduce the volume of these fruitless harangues. After welcoming his audience, and referring to the changes in the hospital staff, the lecturer drew attention to reform in the practice of medicine and surgery. Far too much stress was laid on the necessity of elaborate teaching. Above all, a young man should be taught self-reliance; his own efforts would then pull him through, just as a vigorous constitution was the mainstay of recovery, independent of elegant prescriptions and repeated visits. University discipline and residence were strongly insisted on; healthy tone and lifelong friendships were acquired by this training, in lieu of an entire want of control now felt by hospital teachers over their pupils, and the acquaintance of these young men from the country with interestingly repulsive specimens of shark (*squalidæ*), known as London landladies. The payment and honours conferred on medical men were next criticised: their salaries were simply miserable; hospital physicians and surgeons were for the most part unpaid; Poor-law officers most piteously; surgeons in the services very badly; and young practitioners not at all. For seven years' hard work at the St. Marylebone Dispensary he had received one guinea, and a very distinguished London assistant-physician had found that his salary equalled that earned by the man who put the skid on the omnibus wheels at Holborn-hill. He considered that gratuitous work and its consequent dignity were subjects worthy of woman's consideration, and that ladies desirous of occupying a congenial sphere in the profession might ease the men's shoulders from upholding the work and dignities of unpaid appointments. Mr. Davy challenged the authorities to show reason why ancient coroners should call upon qualified house-surgeons and physicians to give their evidence without fee. Why should the Registrar-General or Commissioners in Lunacy expect skilled services for nothing? The lecturer warmly supported the Contagious Diseases Acts, and was pained at the nonsense which had been let off over vivisection. Practical experiments were as important to medical men as to the Royal Artillery on Dartmoor. In conclusion, he advised everyone to resign at once any and every thought of becoming a medical man unless he possessed three qualifications:—1st, independence; 2nd, an aptitude for, and love of, the profession; 3rd, the readiness to pay a heavy premium in this world for his prospects of reward in the next.

THE
TREATMENT OF SECONDARY AFFECTIONS OF THE HEART.

By J. MILNER FOTHERGILL, M.D., M.R.C.P.,

JUNIOR PHYSICIAN TO THE WEST LONDON HOSPITAL.

(*Concluded from p.* 446.)

It will perhaps best illustrate the subject of this paper to give one or two typical cases; and then to consider the points of diagnostic importance to be attended to in order to recognise secondary affections of the heart, and to discriminate between them and primary affections.

In the latter part of July, 1874, a retired Indian medical officer called on me and asked me to visit his wife. Being engaged that day, and finding it impossible to see her till the morrow, I made inquiries of the gentleman as to her condition. They were old friends of mine, and I knew the lady to be gouty, though she had never had a regular attack of gout in any of her extremities. He told me that his wife had got intermittency of the heart; that it had come on quickly, it not being more than ten days since it was first observed, and that it occurred every third beat very rhythmically. This did not look like true cardiac failure. On inquiring into the other characters of the pulse, he stated that the two beats betwixt each intermission were strong and well sustained. This was an important point, and cleared the diagnosis very satisfactorily. I felt no hesitation in giving it as my opinion that the intermittency was gouty in its origin. To some readers this may seem a bold diagnosis and an unverifiable hypothesis; but it was warranted by the symptoms and vindicated by the results. I gave him a prescription containing iodide of potassium and bicarbonate of potash, in buchu; ordered a slop diet and rest in bed until I could see her the next day. On visiting her the diagnosis was confirmed. The intermittency was already less regular, was no longer rhythmical, and the patient felt better for the treatment. In five days the intermittency had fled and the patient felt almost well, and in a few weeks all sense of illness had disappeared under a combination of iron and alkaline waters. Since then this lady has passed through a sharp attack of bronchitis without any evidence of cardiac debility. In forming the diagnosis in this case, I should not have felt justified in being so positive if previous acquaintance with similar cases had not prepared me for such a conclusion.

At that time I had another lady under care who had suffered repeatedly from suppressed gout, and been under various practitioners, all agreeing in their diagnosis. In this case there was much palpitation, attacks occurring most frequently during the night, when the sensation was that the heart was about to stop altogether. Under a restricted diet, nitrogen being but sparingly admitted, and potash with buchu being administered, great relief was experienced. It was, however, found impossible to get the patient to continue the restricted diet for long, and resumption of the usual dietary and neglect of the medicines always brought back the cardiac trouble, which went off on once more following out the treatment.

Mr. C——, a literary man of much mental activity, consulted me about his heart. He suffered from attacks of dyspnœa, giddiness, and oppression over the heart, which were increasing in force and frequency. There was also numbness down the left arm. This gentleman's father had died of angina pectoris, and he was much alarmed at his symptoms. It appeared that a few weeks only before the consultation he had been in the country and taken severe and prolonged walking exercise without any symptoms of cardiac weakness. He was gouty, and had recently been living well, eating much animal food under the idea that it was the most strengthening diet. A restricted dietary, with potash and buchu, soon relieved him from the attacks, and he has continued well since. This is now fourteen months ago, and he has had no return. When not feeling quite well, he falls back upon his medicine, which soon puts him to rights.

Mr. B——, a retired chemist, consulted me for similar attacks, and under a like treatment he also got relief forthwith, and has since been well as regards his heart troubles.

These are a few out of a number of cases which have come under my notice, in private and in hospital practice, which have presented like features, and which have got well under similar treatment. This latter is a point of much importance. Potash, as a muscle poison, in all its forms, is a powerful depressant of the heart, according to Botkin, of St. Petersburg; and Ringer speaks of the depressing effects of the iodide. If the heart had been primarily at fault there is every reason to suppose that the treatment would have been pernicious rather than beneficial; but being only secondarily affected, the effect of these measures, in improving the depuration of the blood and so doing away with the heightened blood pressure, was to relieve the heart and to disperse the symptoms of cardiac adynamy. It is not easy to say how the buchu acts in these cases. It has been said that it increases the amount of solids in the urine; but this, again, is denied. Certain it is that, in practice, the addition of buchu seems to add to the efficiency of the potash. It forms, at any rate, an agreeable vehicle, and goes well with iron. It is good practice to substitute potassio-tartrate of iron for the iodide of potassium on the relief of the symptoms; and this mixture of potash and iron may be continued with advantage, as a tonic, for some time in these cases. It is also desirable to prescribe mineral waters—Seltzer, Vals, Vichy, Couzan, and others—as a beverage to be taken permanently. With Marsala, claret, or a little gin or Schiedam, they are agreeable to the palate, and act efficiently in helping to remove the products of waste; the accumulation of which forms the condition designated lithiasis, commonly termed "suppressed gout."

The attacks known as gout at the heart are produced by the sudden rise of blood pressure from arteriole spasm and the consequent cardiac embarrassment. It is easy to see how severe and even fatal attacks may be thus induced. Disease of the aortic valves is also common in gouty individuals, and the secondary affections of the heart may be complicated with primary disease of that organ; and in these cases it becomes necessary to discriminate between the two elements of the case. It becomes desirable, in cases of combined secondary and primary heart trouble, to combine the treatment of each form, and to fit complex treatment to complex maladies.

In forming a diagnosis of secondary affections of the heart, and determining that the heart symptoms are really consequential to some prior and causal disturbance of the circulation, there are several points deserving of special notice.

1. The attacks of dyspnœa, palpitation, or sensation of heart stoppage are not induced by effort, but come on independently of any exertion. They not uncommonly come on during great quiet, and even when lying in bed. Not rarely they permit of active exertion, which does not tax the heart in this class of cases; whilst in primary affections of the heart effort always—or almost always, to be very safe—reveals the existing adynamy. A little active movement will render the evidence of true heart failure more pronounced, as I remember well in an old man who used to take a sharp turn round the house to illustrate how exercise made his heart palpitate; while in pure cases of secondary heart affection exertion does not induce the attacks.

2. The pulse is not that of cardiac debility: even when the pulse is very irregular there is a force about it which resists compression, quite different from the irregular compressible pulse of cardiac dilatation. There is indeed the sustained pulse of high blood-pressure in the midst of the irregularity, or intermittency. Not rarely, if the arteries are atheromatous, the irregularity is found along with a full sthenic and powerful pulse—a combination, once well noted, ever afterwards recognisable, though not to be described by words. It is a matter of no slight moment to become familiar with the pulse of these conditions. The feeling of the pulse here is not a mere formal matter, but a measure which often gives valuable indications and directs the line of investigation to be pursued.

3. The first sound of the heart is good usually—loud, clear, and of fair intensity. It preserves its muscular sound and is not simply valvular, and does not approach the second sound in character. When there is much hypertrophy the first sound is loud and long. Not uncommonly there is some reduplication of the first sound from delay in the contraction of one of the ventricles. On examination of the heart, it is found acting well and not giving evidences of lack of power. The rhythm may be disturbed; but there are not evidences of heart failure accompanying the disturbed rhythm.

4. The second sound of the heart is accentuated. This is a most important diagnostic point. In primary disease or debility of the heart this symptom is never found;* in the forms of heart trouble which are the consequences of some prior disturbance of the circulation, causing a rise of blood pressure in the arteries, this objective symptom is never wanting. The accentuation of the second sound will, of course, be more or less intense according to the rise in the blood pressure. It may be found at both the pulmonary and aortic valves. It is most distinct, however, at the aortic valve; and heard most loudly at the second right costo-sternal articulation. The semilunar valves are closed by the recoil of the elastic arteries; if then the tension in the arteries is increased, these valves will be closed with unwonted force, and their closure produces an accentuation of the normal sound. Such accentuation is ever found in the pulmonary valves when the mitral valve is diseased: here it is the measure of the engorgement of the pulmonic circulation. When heard at the aortic orifice this accentuation may be associated with aortic aneurism (Begbie), with general paralysis of the insane (West Riding Asylum Rep., 1873), or with the general rise of blood pressure in lithiasis. It is easy to separate these conditions. The Germans attach great importance to this objective symptom, as might be supposed from their general high estimate of signs whose existence and explanation are clear and rational. If the second sound is produced by the recoil of the elastic arteries, when the blood pressure is abnormally high this sound will be unusually loud. There is no ambiguity about a sign of this kind, and its logical clearness endears it to the Teuton mind. Hence they attach great and deserved importance to this accentuation of the aortic second sound in the diagnosis of chronic Bright's disease; under which circumstances a rise in the blood pressure and this indication of it are most commonly found.

By such means, then, are secondary affections of the heart to be distinguished from the primary affections of that organ. If the examination be made with sufficient care, and there also exist a fair comprehension of the subject in its entirety, the practitioner should be able to discriminate the exact form of the affection; and if there be also some actual cardiac debility, to allow for it, both in the diagnosis and in the selection of the line of treatment. Having decided that the cardiac troubles are secondary to some primitive affection of the vascular system, causing a rise of blood pressure, the principles of treatment are as follows:—

1. To improve blood depuration by removing the accumulated products of nitrogenised waste; and this can be best accomplished by a combination of measures. First: to cut down the nitrogenised elements of the food to the minimum, so as to lessen the production of waste products. Second: to administer potash or lithia in combination with vegetable diuretics, and so to aid in the elimination of waste by the kidneys. This latter action will be assisted by throwing the skin into action.

2. If there be present a certain amount of cardiac debility, the depressant effects of the above treatment may be met by the administration of digitalis along with them.

3. After immediate relief has been furnished it is desirable to administer alkalies together with iron for some time. Contrary to what is indicated in primary debility of the heart, the diet should be restricted, and the amount of nitrogen in the ingesta should be small.†

---

* This accentuation is not to be confounded with the brief but loud second sound of unfilled vessels; often this is only pulmonary.

† The recent papers of Parkes, as to the effect of a non-nitrogenised diet upon the blood pressure, lowering it very remarkably, are very suggestive as to the diet of persons suffering from secondary affections of the heart. (THE LANCET, May 23rd and 30th, 1874.)

4. Active exercise in these cases is rather indicated than otherwise, and the increased oxidation induced thereby is beneficial, while the exertion does not act injuriously upon the heart.

The neurosal affections of the heart require a treatment of their own. What the indications for treatment are in this class of diseases will need another and concluding communication.

Lower Seymour-street, W.

ON SOME EFFECTS OF MODERN RIFLE PROJECTILES.

BY DR. HUGO SENFTLEBEN,
LATE STAFF-SURGEON WITH THE 61ST PRUSSIAN INFANTRY IN FRANCE.

IT is a well-known fact that each party in the late Franco-German war charged the other with using explosive bullets for small arms, in violation of the treaty proposed by Russia and accepted by most of the European powers, which forbade any explosive projectile weighing under one pound. Even the Prime Minister of Germany made such allegations the subject of diplomatic representation; and not only the French newspapers brought similar accusations against the Prussian soldiery, but I had myself, unluckily, to experience reproaches of the same kind on the part of French officers, when, after the last of the bloody encounters with the army of the Vosges, a Garibaldian colonel detained me as prisoner of war because I had remained single on the battle-ground to attend upon the wounded of both parties.

I have endeavoured in vain to find any scientific reasons stated in support of those angry recriminations, though I am not at all surprised to have heard them repeated by soldiers who saw the effect and judged from the appearance of hostile rifle projectiles when in the act of striking. It is, however, the great force of propulsion which modern rifles give to their elongated bullets, and the much more frequent skirmishing in mountainous districts, and the village and town fights, which offer numerous occasions for *ricochets* and *splitting* of *projectiles*, that give us an easy and natural explanation for many cases of reputed violation of a now *established* international law. The very destructive effects which are made in the animal body by the explosive bullets used in the chase of large game prove the wisdom and humanity of such a law; and when the journals of Lyons announced the arrival of a renowned lion-hunter from Algeria amongst Garibaldi's sharpshooters, the news was a little trying to those of his enemies who believed in the rumours of French faithlessness to the contract. But during the three days' hard fighting around Dijon in January, 1871, and at the subsequent surprise in Prauthoy, I have seen nothing that could confirm suspicions of the kind, though I frequently noticed balls that struck a wall split up and dispersed in pieces, as if they were exploding, like liquid metal falling from a height on stony ground.

The aptitude to change form and to break up into irregular and jagged fragments when hitting on a stone or metal, as steel, brass, or iron, depends not only on the initial velocity and the consequent strength of impact, at even longer distances, but also very materially on the composition of the ball. Pure lead, as it was used with the Austrian Lorenz rifle in 1866, the German needlegun of Dreyse, and the old French Minié muzzle-loaders, or those converted on the Snider principle into breech-loaders *à la tabatière*, splits much more easily than the bullet of the Chassepôt or others of the modern breech and magazine loaders, which are hardened by an alloy of tin (the Henry-Martini projectile, e.g., contains 1 : 12 of lead). The latter penetrate more easily the tissues of the animal body, and shatter—if their force of propulsion (i. e., initial velocity) and weight be equal—more readily the bones without changing their form, as Professor Longmore had sagaciously pointed out beforehand ("On the probable Surgical Effects in Battle in case of the Employment of Projectiles of a more Elongated Form"—*Army Medical Rep.*, vol. v., 1865). They resemble in this respect grapeshot, which is so much more destructive than the old round musket-ball. The reputed destructiveness of the Dreyse rifle projectile—the Prussian "langblei" (elongated lead)—depended, on the contrary, on its greater propensity to break up and hurt through its sharp-edged débris. I remember the case of an Austrian foot soldier from Servia, who was wounded at Koeniggraetz by a "langblei," and, with a fractured tibia, had been at some hospital in Saxony. Three weeks after the battle he came under my care at Berlin, walking into the ward with a stick in company with others. For some days he could scarcely be kept in bed, until he began to complain of violent pains and repeated hæmorrhage set in. There were two openings in the leg at the middle of the calf, showing entrance and exit of the ball. Four weeks after receipt of the injury I was called to see him, when he was nearly pulseless from loss of blood. An incision led into a large hollow filled with clots, fragments of bone (the tibia was broken through), and some sharp-pointed pieces of lead. The circular amputation below the knee, which I performed immediately, saved the man's life, who made a very quick recovery; and I found the posterior tibial artery injured and ulcerated for the length of nearly an inch by contact with those spiculæ of metal, which but for their dangerous sharpness would have been comparatively harmless. There are plenty of similar cases on record. The power of the hardened Chassepôt bullet may, however, act with very great effect on a bone without causing any deformity of the projectile. I saw a remarkable instance of this when in garrison at Belfort during the armistice. The surgeon in charge of the German soldiers wounded during the siege consulted me about a Landwehr artillery-man, thirty-nine years old, who had in a night assault been struck by a Chassepôt projectile, which entered his shoulder-joint from above at very short distance, and left the arm at the lower insertion of the deltoid muscle, without losing its shape. Two months had elapsed, and the patient was nearly exhausted by septicæmic attacks from destruction of the joint, which I found transformed into an abscess discharging incompletely through two or three fistulous openings at the usual points. I made an incision through the wasted deltoideus, emptied several ounces of stinking pus, and, on introducing my finger, found the articular head of the humerus broken off at the anatomical neck and forced like a wedge between the two portions of the longitudinally cleft diaphysis, which, being only partly divided, acted like a pair of pincers, and kept the detached fragment entirely jammed. With some difficulty I extricated the latter; there was no other necrosed bone, and the patient did so well that he was soon afterwards sent to Germany. The very elasticity of the fissured shaft proved that the fracture and impaction of so small a portion as the anatomical head was not due to morbid fragility of the osseous tissue, but to the extraordinary propelling power of the *hardened* bullet. So I have observed a Chassepôt penetrate both knee-joints, crushing the condyles, and cut it out unaltered in shape from under the skin of the outer joint.

Where greatly deformed or broken projectiles are found in wounds, a doubt may arise whether such deformation or breakage be caused by the ball expending its force on the bone, or whether it entered the body after rebounding from some harder substance, and becoming deformed or split up before striking the osseous tissue. The appearance of the entrance opening seems to be less important for deciding this question than the shape of the metal itself. Even soft lead bullets will seldom acquire so jagged and torn forms by impact on bone as they present when ricochetting from some harder metal or stone. Two very instructive cases of this kind came under my notice after the battle of Woerth, when some of the French wounded were sent up by rail to the fortress of Minden, where I was engaged in establishing a reserve hospital. Both soldiers had the humerus broken at its upper third in a very similar manner—a simple horizontal fracture with the projectile lodging. One was a Cuirassier belonging to those famous but unfortunate squadrons of Reichshofen, the other a little, fat, old woman-like Zouave, who lamented loudly when I cut out the ball, whereas the Norman horseman looked on the same operation with sombre and stoical mien. The unburied masses of lead were much like each other, quite shapeless, like a piece of molten metal thrown into water and suddenly cooled; the Cuirassier's was rather more flattened and jagged. Had these Frenchmen received the Prussian "langblei" direct from the rifles the fractures of their arms ought to have been splintered, judging from the deformity of the projectiles; but the lighter nature of the injuries, and the circumstances under which they were inflicted, pointed to an indirect course. The horseman's ball had evidently rebounded from his own or his neighbour's steel breastplate when they were charging; the other had been struck *par ricochet* in a skirmish between stone walls.

Injuries of the soft parts effected by deformed or split projectiles hitting indirectly must be very numerous in modern warfare. The frequent fights in the French vineyards favoured them particularly, and caused many of the slighter wounds. Before Dijon I had made quite a collection of such Chassepôt balls, altered in their shape in the peculiar manner which gives them the appearance of a mushroom, with broad stem and an overlapping flat top; this latter representing the compressed forepart, the former the posterior unchanged end of the projectile. Several of them were cut out from close under the skin, which they had just penetrated; and though their power of percussion had been nearly expended, the opening in the skin appeared always like a simple slit, not as an irregular or crushed punch-hole. The ricochetting soft lead bullets of the Dreyse and the French *tabatière* rifles showed, as a rule, a much larger amount of deformity, their original shape being often altogether lost; their weight and size being at the same time greater than the Chassepôt (the latter weighing only 380 grains against 480 and 530 of the former), the width of their channels and the laceration of the soft tissues they caused were consequently larger. On the third day of Dijon a non-commissioned officer of the 21st Prussian Foot, who had been, as skirmisher, lying flat on the slope of a railway embankment, came to our ambulance (Verbandplatz) with a wound in the lower maxillary region into which I could introduce two fingers, finding a rather large bag between the larynx and lower jaw, partly filled with blood-clots and torn muscle, but no foreign bodies. The patient, an examined student of Catholic theology, who was not yet consecrated as a priest, told me that he had been aiming his own rifle when something struck the side of his throat. Whilst I was still probing the entrance channel one of my assistants had removed the man's shirt, and pointed to a swelling over his shoulder-blade. The large deformed Minié projectile which I cut out over the lower angle of the scapula had nowhere touched a bone, but must have been flattened, before entering the body, on some hard substance outside.

It was a remarkable fact that the tales of French explosive bullets became so much more frequent in the latter part of the war, when those *tabatière* rifles with their soft lead bullets came into play. They were, however, circulated even at the commencement, when only the hardened but with high initial velocity cast Chassepôts were in use. There is no doubt that these latter may also split on hard substances from their strength of impact (the power of percussion they show in the animal body or any other softer materials), which, as is well known, increases in an inverse ratio with the square of the distance from which the rifle is fired. The greater initial velocity of modern rifles, owing to improvements in workmanship, in the material of barrels, superior grooving and lubricating, the shape of the bullet and the strength of the powder, to the relatively smaller weight of the former and the greater charges of the latter, has been identical with a growing perforating force of their projectiles, as I sketched out before the outbreak of the last Continental war, in a paper entitled "Zur Wundaerztlichen Waffenkunde," printed in the *Deutsche Klinik*, 1870, Nos. 4, 5, and 7. On the one part greater power to shatter bones is the consequence thereof, on the other an increased tendency to ricochet and hurt indirectly after deformation or breaking up into pieces. The corrective to this dangerous improvement of weapons must be found in the farther distances people keep from each other on the battlefield and skirmishing from behind coverings. The surgeon's aid in combating the more disastrous results of scientific arms must provide for careful examination of the wounds, prompt removal of foreign bodies, and the utmost conservative treatment on antiseptic principles.

The allegations which French surgeons made in the Crimean war—M. Scrive, for instance,—that the Russians had used explosive cylindro-conical bullets of copper, have never been proved; but the medical officers of the British army—as Longmore and Macleod—saw frequently cases of injuries through pieces of conical balls which had split on the rocky soil. The Prussian "Granatgewehr," a heavy rifle which throws a shell of about four ounces' weight, has never been made use of during the late or any former war. Explosive bullets containing a smoke-producing charge—as, for instance, thrown by the long-range Metcalfe rifle—may be very useful for judging distances; it seems, however, doubtful if they will be, under present circumstances, introduced into so-called civilised warfare.

The new Gras rifle of the French, an improved Chassepôt, seems to be in several respects a superior weapon. Besides a metal cartridge, made of *red* copper (which is the most ductile material to close the breech effectually—much more so than yellow copper or brass, as in the Boxer and other cartridges), a better kind of powder, containing less sulphur and soiling less the barrel, is used for it. From a different construction of the breech-chamber the initial velocity of the bullet is higher, though its weight has slightly increased and the powder-charge diminished. The bullet, it seems, is made of compressed lead, instead of an alloy, to secure hardness. From the *Spectateur Militaire* I give the following statements:—

	Gras Rifle.	Old Chassepôt.
Weight of bullet ...	25 grammes ...	24·50 grammes.
Calibre of bullet at the bottom ...	10·9 mm. ...	11·8 mm.
Length of bullet ...	27·75 mm. ...	25·30 mm.
Powder charge ...	5·25 grammes	5·50 grammes.
Initial velocity ...	455 metres ...	410 metres.

A German military periodical gives the weight of the bullet for the Mauser rifle as 25 grammes, equal to that of the Gras; the powder-charge of the German arm as only 5 grm. The initial velocities of the regulation rifle bullets in the German and Russian armies are stated as follows:—

Mauser	430·0	metres	per second.
Werder (Bavarian) ...	432·7	"	"
Berdan (Russian)	449·0	"	"

The Gras rifle appears, therefore, in this respect superior to them all. The absolute and relative number of rifle-ball wounds *par ricochet* depends, however, not only on the greater force of propulsion and percussion, but also on the quicker firing and greater number of bullets spent in modern warfare. In the report of the American Army Commission on modern rifles it was, some years ago, pointed out that the weapon of the future would be the repeating rifle, or magazine loader. Modern artillery is very destructive; but well-trained infantry will always remain the backbone of armies. The recent war proves that 90 per cent. of the killed and wounded were injured by rifle bullets; the infantry lost 17 per cent. of its men in killed and wounded, the other arms but 6 per cent.

EPIDEMIC OF HYSTERICAL EPILEPSY AND TETANUS.

BY STAFF-SURG. JOHN HUDSON, R.N., L.R.C.P. LOND. &c.
LATE SUPERINTENDENT OF THE EMIGRANT SHIP "EARL DALHOUSIE."

THE outbreak comprised eighteen cases—eight married and ten single women, ranging from seventeen to thirty-one years of age,—and varied in form and intensity from simple hysteria and fainting to strong convulsions and prolonged general spasms (complete opisthotonos). The varieties corresponded with the intellectual, moral, and physical characteristics of the patients.

The immediate exciting causes were—1st. The pre-existing case of Susan B——. 2nd. The first case (that of Mrs. S——) in the general outbreak of Dec. 28th, occurring at 2 P.M., in a violent and striking form, and arising from jealousy, in an excitable, epileptic subject; and seen or talked about by those that followed during the same evening. 3rd. The sympathetic influence affecting the community. 4th. The exciting effects of heat (82° to 85° in the shade) and climate in crossing the equator. 5th. Nymphomania, and the consequences of masturbation; this habit being no sooner admitted and the patient duly admonished than a total cessation of all the symptoms at once ensued.

The following is an abstract of a few typical cases.

Case 1.—Susan B——, aged twenty-two, of spare habit, intelligent, and healthy-looking, was found in bed prostrate and unconscious on the 5th December, 1874, (the day after going to sea). It came out that she had been to sea, as a girl of ten years, with her father as a ship master; that she became a mother at fifteen, and afterwards the subject of parental harshness and of restraint in a workhouse asylum. She was the victim of nymphomania. The attacks were long, strong, frequent, and of persistent character, being excited by sudden shocks—as from noises or flashes of light—and often, when in bed at night, without apparent cause, until they finally ceased with the habit which had induced them, having lasted from 5th December to 7th February, with various remissions or intervals of calm, rational, and good behaviour, alternating with threats and feigned attempts to commit suicide; the patient now being peevish, quarrelsome, perverse, deceitful; then pulling her hair and malingering, in order to excite sympathy. When delirious or ecstatic, or under the first effects of chloral hydrate, &c., her mind would betray signs of good and evil training, such as bad language and pretty hymns.

The general symptoms were intolerance of light, with a sense of "fire in the head," hyperæsthesia of left side of face, neuralgia, temporary paralysis and spasms of eyelids, face, neck, throat, &c., involving the muscles of expression, speech, deglutition, and voice, on one or both, but mostly the left side. During an attack or "fit" the convulsive action extended to the chest, the arms, and more or less to the whole body, lasting from a few minutes to half an hour, and merging into complete and general rigidity (opisthotonos), the body being arched backwards, so as to rest on the head and heels, but rarely inclined to the right side. This general spasm or tetanus usually lasted from ten minutes to several hours; in a few instances the patient remained stiff and unconscious, as in a state of catalepsy, for twenty-four to thirty-six hours.

This description of S. B——'s state of mind and of the nature of the attacks is applicable to the cases that follow, a few peculiarities only of each being subjoined.

Case 2.—Mrs. S——, aged twenty-six, of spare habit, pale, epileptic aspect, and lively disposition. This case, which took place on Dec. 28th, was the first of the general outbreak, and had been subject to some complaint for several years in Sydney. Excited by jealousy, &c. The case was remarkable for the violence and duration of the attacks, also for the delusions and vagaries, followed by the feigning and deception which she practised. Symptoms as in the first case, with greater intelligence and *colonial acuteness*, great agitation, subsultus tendinum, &c.; strong convulsions, extreme rigidity of the body, and, while ecstatic, fancying herself about to be buried at sea, and asking to be "lowered gently." Lastly, the stage of imposture having set in and being detected on Jan. 16th, 1875, she straightway recovered, and returned to her berth in the married compartment.

Case 3.—Mrs. Anna M. G——, aged thirty-one; of seven years' standing from trouble and uterine weakness (abortions, &c.); present attack severe, and brought on by sight of others in a weak and delicate woman.

Case 4.—Harriet W——, aged twenty-five, stout and *apparently* listless and phlegmatic, was one of ten cases which immediately broke out after the preceding (night of Dec. 28th). She was conspicuous for her moral and intellectual attainments. The fit commenced with syncope and hysterical screaming, followed by singing and talking (soliloquy) for an hour or more after a dose of chloral, &c. While reclining on the poop she had calm and lucid intervals alternating with a state of abstraction, in which were disclosed evidences of a moral and cultivated mind. At one time she was singing, in fine musical and feeling tones, a favourite song in German, as if it had been the secret of her life; at another, she was instructing an imaginary class of children in the art of singing; and anon I was impressed by her minutely expounding the Epistle of St. Paul to Philemon, gently exhorting her little pupils to "speak up," so that she might hear them. On Dec. 31st she was clear and calm, felt her mind active, and said "We don't so readily get over broken hearts." Strange as it may seem, all this was soon succeeded by disobedient and perverse conduct, threatening us with "more trouble before she had done"; and ending with a becoming apology on the 1st February.

The cases of Amy L——, aged twenty, Annie M——, aged twenty-one, Eliza H——, aged nineteen, arose in stout, robust, headstrong young women, of neglected training and education, the attacks being strongly marked with a predominance of the animal spirits.

The nine remaining cases occurred in young married and single women from twenty to twenty-five years of age, of excitable, hysterical constitutions, and in forms varying from vague fears and hallucinations to unconsciousness, extreme convulsions, and stiffness of the whole body. The immediate cause of all was probably emotional, and the nature of each apparently a reflex action of the nervous centres.

Contrary to a prevalent opinion in such cases, in no instance were the uterine functions or the general health materially affected, except from weakness. All ultimately recovered, and, indeed, I have only known one extreme case of this affliction to terminate in death—viz., that of a young lady, aged twenty-seven, who for the last six months of her sufferings was unable to endure the least sound or ray of light.

The treatment consisted in the administration of chloral hydrate, potassium bromide, henbane, valerian, and aperients; of bleeding to twenty ounces in one instance; of cold to the head, and of placing the patients on their beds on the deck for safety, &c.

CASE OF IMPACTION OF AN IRON STAPLE IN THE ŒSOPHAGUS.

By W. WATSON DOVE,

ASSISTANT MEDICAL OFFICER, SOMERSET COUNTY LUNATIC ASYLUM.

J. W——, aged thirty-nine, who has been an inmate of the Somerset County Lunatic Asylum since 1862, was noticed of late to have been getting very thin, and to suffer from loss of appetite. On inquiring what was the matter with him, he said that "he could not eat from pain and difficulty in swallowing, and thought he must have got something in his throat, but did not know what."

On examining him nothing could be seen by looking down his throat, but on passing a probang down the œsophagus it was stopped about half-way by some foreign substance. Not knowing what it might be, I withdrew the probang and examined his throat externally. I could feel behind the trachea, just below the pomum Adami, a hard lump, but could not distinguish its shape. I therefore thought it best to let him alone, and trust to the substance, whatever it might be, coming away of itself. He was accordingly sent to the infirmary on the 21st of August, 1875, and lived for the most part on beef-tea and arrowroot, occasionally trying to take solid food. A few days after he had been in the infirmary he told the nurse that he had swallowed a staple, but when questioned further, said "he didn't know what it was, but that he had swallowed something." On the 29th September last, whilst trying to eat some meat, he very nearly choked. The nurse at once put her finger down his throat and withdrew the meat, and with it an iron staple weighing four drachms five grains. Its transverse measurement was 1¼ in., and its greatest length 2⅛ in. It was much blackened and corroded.

The patient complained of a little pain the day after the staple came away, but was able to take solid food and apparently enjoy it.

On the 1st of October he told me that he had pulled it out of a wall in the airing-court, that he put it in his mouth convex end first, then turned it round and swallowed it points foremost. He is now doing well.

Presentation.—Dr. Elliott, the house-surgeon of the Bristol General Hospital, was lately presented with a handsome walnut Davenport and silver plate, bearing the following inscription:—"Presented to Dr. Thomas Elliott, by the officers, students, nurses, and patients of the Bristol General Hospital, on his resignation of the house-surgeoncy. Sept. 1875"; also, a pocket instrument-case.

LONDON HOSPITAL.

GASTROSTOMY FOR CANCER OF THE ŒSOPHAGUS.

(Under the care of Dr. Fenwick.)

The following notes were taken by Mr. S. D. Clippingdale.

Sarah B——, aged thirty-four, admitted April 16th, 1875. She stated that she had had good health until nine months ago, when she was suddenly affected with difficulty in swallowing. There was no pain until three months later. Since then solid food seemed to meet with a "stoppage at the pit of the stomach," and excited intense pain until returned; liquids produced no pain, but a choking sensation.

When admitted, the patient was emaciated and anæmic. She complained much of hunger, but more of thirst. A bougie passed into the œsophagus was suddenly arrested 15½ in. from the teeth. The abdomen was retracted. On full inspiration a number of small nodular masses, like enlarged glands, could be felt immediately below the ensiform cartilage. This part was tender, and was the part to which the pain during deglutition was referred. Milk taken was vomited immediately, and in consequence she was fed chiefly by enemata.

April 24th.—The vomiting continues. Enemata only retained when brandy is added.

May 26th.—Still unable to swallow solid food, and the power of retaining liquids varies at different times. Still fed chiefly by enemata.

June 7th.—A small œsophageal tube can now be passed; it passes through a painful stricture, and then enters the stomach. By means of this tube a meal of milk, eggs, and brandy is administered twice a day, and great relief afforded to the patient.

17th.—Has gained 2½ lb. in weight during a week. Pain is no longer produced by the passage of the instrument.

23rd.—The stricture now resists the passage of the tube, and even a smaller one could not be passed until a hypodermic injection of morphia had been given.

26th.—The smallest-sized tube, equal in diameter to a No. 7 urethral catheter, passed to-day with a little force.

28th.—No tube can be passed. Enemata are given, and retained about three hours.

Aug. 25th.—The enemata of milk and brandy, after a few days' use, were not retained. Dr. Fenwick ordered pepsine to be added. The injections so made were retained for some hours, and patient expressed herself as feeling greatly relieved. These enemata, however, were eventually returned as the others had been. Other plans for allaying the irritability of the intestinal mucous membrane met with only partial success.

Gastrostomy.—Aug. 30th: The patient becoming rapidly weaker, Mr. Waren Tay, after several consultations, and at the patient's earnest request, determined to perform gastrostomy. At 3 P.M. ether was administered, and the operation commenced by a vertical incision along the outer border of the left rectus muscle, commencing above at the margin of the costal cartilages, and extending downwards about two inches. The aponeuroses of the abdominal muscles and the transversalis fascia were next divided upon a director, and the peritoneal cavity opened. Mr. Tay found the stomach without difficulty, and the exposed part, which was free from disease, was attached to the abdominal wall as the intestine is in colotomy. Considerable hæmorrhage occurred when the stomach was incised, and two ligatures were necessary. An india-rubber tube was placed in the stomach through the wound, and retained there until the patient's death. After the operation another enema of milk and brandy with pepsine was given.

After-treatment. (For the following notes we are indebted to Mr. Rudduck, the house-surgeon.)—Aug. 30th, 8 P.M.: Patient complains of great thirst; temperature 96·6° F., pulse 88; the hands and feet are very cold. Ordered to be wrapped in cotton-wool. 10 P.M.: Mr. Tay introduced a little ice and about an ounce of milk into the stomach. She felt it going in, and says it satisfied her; it did not give her much pain. Another enema was given.—Aug. 31st, 1 A.M.: A little more milk introduced. Nurse says that given three hours ago trickled out afterwards. 8.30 A.M.: Has passed a quiet night. Temperature 98·6°. Says she feels better than she did yesterday. About half an ounce of warm milk and water put into the stomach. This seemed to excite a great secretion of gastric juice, as a large quantity trickled out. In about half an hour afterwards the nurse noticed that the dressings were soiled with the milk. 11 A.M.: Patient is very low; can scarcely articulate; pulse 124, very feeble. To have a brandy enema immediately. 12.30: Rallied considerably, though the greater part of the enema was returned. Mr. Tay introduced a little brandy into the stomach, but a good deal of it was forced out at every inspiration. 3 P.M.: As the food comes away so much, a piece of gutta-percha tissue was sealed over the orifice, and the tube left protruding through this. The tube was plugged with a catheter stilette, and the patient turned over on her right side, as she retains most food in this position. Temperature 98·6°. 5 P.M.: A little more food introduced. Patient seems sinking into coma. Pulse 144. The abdomen seems rather swollen. 7 P.M.: About the same quantity (about half an ounce) of brandy and milk introduced. 9 P.M.: Pulse extremely small. Patient a little delirious, evidently moribund. Died about 10 o'clock.

The autopsy was made eighteen hours after death by Dr. Sutton. The following notes are abstracted from the hospital register:—Body weighed 3 st. 7 lb. Temperature 68°. The incision in the stomach was found to be about the middle of the anterior surface. The lower end of the incision was close to the greater curvature. Its margin was adherent to that of the opening in the parietes. The peritoneum around was congested, and there was recent lymph on the right lobe of the liver and on the stomach. The stomach and liver were adherent by old adhesions. A mass was found at the lower end of the œsophagus; it was composed of medullary cancer, was about two inches thick, and extended throughout the coats of the œsophagus. About an inch and a half from the stomach the canal was blocked by a quantity of juicy soft débris. The rest of the œsophagus and the stomach were apparently of healthy structure. There were some commencing phthisical changes in the lungs. There were no noticeable changes in other organs.

ST. THOMAS'S HOSPITAL.

HÆMORRHAGE FOLLOWING TOOTH EXTRACTION.

(Under the care of Mr. Wagstaffe.)

For the notes of this case we are indebted to the kindness of Mr. H. P. Potter, house-surgeon.

A man, T. W——, aged thirty-three, was admitted into Leopold ward on Tuesday, August 10th, for hæmorrhage from the seat of a tooth drawn on the previous Friday. He gave a history of always bleeding freely from slight causes, and he stated that about twelve years ago he had a tooth extracted, after which he bled for eight days. The hæmorrhage was stopped with the actual cautery.

The tooth drawn on the 6th August was a large molar on the left side. As the bleeding was profuse, the patient had medical treatment outside the hospital for four days.

On the 10th August, in consequence of the hæmorrhage continuing, and as the ordinary means for its arrest had not succeeded, the patient was admitted. He was not much affected by the loss of blood, and looked healthy. The clots were removed from the mouth, and the bleeding surface discovered, which appeared to be the whole of the tooth cavity and the surrounding gum. Plugs of lint were used steeped in a strong solution of perchloride of iron, and the teeth pressed firmly together with a bandage beneath the jaw. This stopped the bleeding for several hours, but on account of the reappearance of hæmorrhage, the solid perchloride of iron was used, and with better effect. The latter, however, caused much irritation and swelling of the face.

August 13th.—Feels very weak; lost about half a pint of blood during the day. Patient takes a fair quantity of milk.

14th.—Bleeding very profuse; no good result from graduated pad and solid perchloride of iron. As the man was becoming very weak, the application of the hot iron was decided upon. This was done under the influence of ether.

15th.—Hæmorrhage ceased for twenty hours, but at the end of that time it reappeared.

17th.—Actual cautery used, which stopped the bleeding for eighteen hours.

18th.—Bleeding profusely at 2 A.M.; cavity firmly plugged with cotton-wool saturated with solution of iron; subcutaneous injection of one grain of ergotin every day.

20th.—No improvement in patient; blood can be seen to well up from the tooth cavity; face much swollen; occasional attacks of delirium.

21st.—Cavity plugged with gutta-percha, and afterwards with plaster-of-Paris, neither of which succeeded in stopping the bleeding.

23rd.—Patient has been losing about a pint of blood daily for the last three days. Has become very exhausted and pallid; speaks of noises in his ears and bright objects before his eyes. Ten grains of gallic acid given internally every two hours, and a subcutaneous injection of morphia at noon and midnight.

24th.—Less bleeding to-day. Takes a fair amount of nourishment.

25th.—Bled about five ounces this morning. Plugged with cotton wool and strong solution of perchloride of iron.

27th.—No bleeding for forty hours. Patient feels a little stronger, but has a very anæmic and peaked appearance.

Sept. 1st.—Commenced solid food.

2nd.—Up for the first time since illness.

5th.—Left the hospital.

Remarks. — Cases of prolonged hæmorrhage after extraction of teeth are sufficiently uncommon to make them of interest; and when the bleeding continues, as it did in this case, over so long a period (fifteen days), notwithstanding very active means being employed, the case then becomes alarming, both to patient and surgeon. It is worthy of notice that, in the present instance, the blood appeared normal in its coagulating powers, and therefore unlike many of the recorded cases of hæmorrhagic diathesis where the thinness and non-coagulability of the blood point to an alteration in its physical and chemical characters. Here it coagulated firmly and quickly. Throughout the case the pulse and temperature remained at their normal standard. Thirst was a marked symptom. It was found that the actual cautery arrested hæmorrhage for some hours; but, on account of its bringing away incinerated tissue, the results of its use were inferior to firm plugging with the strong solution of the perchloride of iron.

BRISTOL ROYAL INFIRMARY.

ACUTE RHEUMATISM, WITH HYPERPYREXIA, TREATED WITH THE COLD-WATER COIL.

(Under the care of Dr. R. Shingleton Smith.)

E. H——, aged thirty-nine, carpenter, married, admitted into the infirmary, Ward 5, on June 1st, 1875, with acute rheumatism. There was no history of rheumatism in his family, and it was his first attack. He had been getting about up till four days before admission, but had complained of pain in the back for two months previously. There was no known cause for the present attack, which commenced with pain in the right ankle; the left ankle then became affected, with redness and swelling; and on the day following the left knee and the wrist of the same side became painful, afterwards the right shoulder and wrist. Had been a Good Templar for two years past, but before that period was accustomed to drink freely.

On admission he was noticed to be a rather anæmic-looking but otherwise robust and well-nourished man. His temperature was 102°, the skin perspiring freely. He complained of pain in both ankles, left knee, wrist, and shoulder, and also in the right wrist and shoulder. There was considerable swelling of both ankles, and some effusion in the left knee-joint. Pulse 108, full and hard; breathing normal; no abnormal chest-sounds audible; tongue white and moist. He had been unable to sleep for three nights previously. Ordered blistering fluid to be applied to the swollen joints, and a saline mixture containing a drachm of citrate of potash with half a drachm of bicarbonate of potash to be given with tartaric acid, effervescing, every four hours.

The day following his condition was much the same; the morning temperature was 102·6°, the evening 102·4°. The urine was decidedly alkaline in reaction.

June 4th.—He was comparatively free from pain; the swelling of the joints had subsided; the urine continued alkaline. Morning temperature was 101·2°, evening 102°. He still perspired freely, and a copious crop of sudamina had appeared on the chest. Was ordered a chloral hydrate draught, with bromide of potassium at bedtime, as there was still little disposition to sleep.

7th.—Morning temperature 100°, evening 102·4°.

On June 12th the morning temperature was 102·2°. At midday he expressed himself as being no worse, was free from pain, could move the legs and arms without difficulty, was perspiring freely, and was covered with a very thick eruption of sudamina. The pulse, which on previous days had varied between 108 and 97, was now 100. There was no distress in breathing; the urine was still decidedly alkaline; had slept better since taking the night-draught. On examining the chest a decided systolic friction sound was audible over the base of the heart, but there was no increase of pericardial dulness. Six leeches were applied over the cardiac area, and he was ordered to continue with the alkaline mixture. At 6 P.M. (June 12th) the temperature had gone up to 105·8°, and at 9 o'clock it was 107·4°, at 10.30 it was 106·8°, and at 11 o'clock it was again 107·4°. The pulse was 136, and the respiration 44; delirium of a low muttering character was first noticed. Roberts's coil was then applied, and a stream of water, at a temperature varying from 42° to 46° Fahr., allowed to flow through it. The temperature of the patient was taken every fifteen minutes, and varied from 107° at 11.15 A.M. to 106·6° at 2.15 P.M., and gradually falling until 9.15, when it was 100·2°. The coil was then removed, and the temperature taken as before. At 9.30 P.M. it was 103·4°, and at 11.15 P.M. 102·2°. This was the lowest point reached. It then began to go up again. At 12 A.M. it was 103·4°, and rose till 4.30 A.M., when it was 106°. At 4.40 A.M. (June 13th) the coil was readjusted, the temperature of the water flowing through it being, at its entrance 44°, at its exit 57°. At 4.45 the temperature was 106·4°; this was the highest point. A gradual descent then followed till 9 o'clock, when the thermometer recorded 100·8°.

14th.—He was still delirious, but was free from pain. Pulse at midday 128, of fair volume and force; respiration 40; mucous râles heard over both lungs in front. There was some slight increase in pericardial dulness, and heart-sounds were indistinct. Faint double friction was audible. At 9 P.M. he was very desponding, and had a conviction that he would not recover. Six ounces of brandy had been ordered, but he refused to take any nourishment, on the ground that he would not break his Good Templar pledge; accordingly nutrient enemata were ordered. The pulse was much smaller and more compressible than it had been, and his feet were cold; the coil was therefore removed, after having been working continuously for twenty-eight hours. During the night his temperature varied from 100·8° at 10 P.M. to 103·2° at 5 A.M. The coil was at this point re-applied; and at 11.45 the temperature had sunk to 100°. All through the night the temperature, registered regularly every fifteen minutes, continued steadily at 100°; and on the 16th, at 12 P.M., it was 99·4°. He had taken his milk, and the brandy as well (but he was unconscious of the latter), without difficulty, so that the enemata were not repeated. He was very drowsy, and had a rather dusky aspect. The pulse was 120; respiration 32 (2 P.M.) The heart-sounds were more distinct; no friction-sound could be heard. There was slight increase of cardiac dulness; mucous râles were heard, especially over the left lung. The bladder was found to be distended, and the urine was removed with catheter; it was found to have an alkaline reaction, and to be free from albumen. He was ordered to take a mixture containing five grains of quinine, alternating with a carbonate of ammonia and ether mixture, every few hours. The coil was now discontinued at 2.30 P.M., having been applied continuously since 5 A.M. of the day before. Towards evening his temperature again rose somewhat, but declined to 100° on the following morning.

17th.—At midday he was still drowsy, but easily roused. Breathing much improved. Pulse 120, of fair volume and power; respiration 36. No articular pain or swellings, but both feet had become slightly œdematous. The urine was found to be slightly acid in reaction, sp. gr. 1016, no albumen. The coil had not been used since 2.30 on the previous day. Towards night the temperature again ran up.

18th.—At midday the patient was in a very apathetic condition, but expressed himself as feeling better. He wandered in his talk, and wished to be allowed to get up. 10 A.M.: Pulse 132; respiration 40.—2.15: Pulse 148; respiration 50.—4: Pulse 160; respiration 52. The heart sounds were obscured by mucous râles; no friction could be heard, and there was no increase of dulness. Behind, at lower part of chest, percussion note was less resonant than normally, particularly on the right side, but there was no bronchial breathing. An emetic powder of sulphate of zinc was given, but without causing vomiting. Twelve ounces of brandy was ordered. At 4 P.M., the temperature being 106°, the cold water coil was again applied to the back as before; at 4.15 the temperature was 105·6°, and at midnight it had fallen to 99°, after eight hours' application.

On the 19th it again rose from 99·8° at 1 A.M. to 106·9° at 3.30. Again the coil was applied, and the temperature fell from 106·9° at 3.45 to 100·8° at 2.15 A.M. on the 20th. At midday on the 19th he seemed very prostrate, had been perspiring freely, but there was no articular affection, and no complaint of pain. Face was rather dusky, and there was constant stupor. Breathing was laboured; mucous râles were heard over front of chest on both sides, and there was mucous rattling in the throat, but little tendency to cough, and no expectoration; respiration 40. A 2 o'clock pulse was 148, weak, dichrotous. He still took all his nourishment freely, including the twelve ounces of brandy.

Death took place at 2.30 A.M. on the 20th, the temperature having come down to 100·8°.

Autopsy, thirty-four hours after death.—There was no excess of fluid in the pericardium; both surfaces were covered with a layer of lymph, of the usual honeycombed structure and appearance, the two surfaces being bound together by soft bands of recent lymph, which could be torn through without difficulty. The muscular structure of the heart was found to be healthy. The endocardium was not affected, excepting that the auricular surface of the mitral valve had a row of small, firm, fibrinous, warty beads along its edge. The aorta presented unusual appearances for a man only thirty-eight years of age. It was universally mottled with yellow atheromatous-looking patches, scattered over the coats of the vessel along its whole length, from the aortic valves to the bifurcation into the iliac trunks. Thickened yellowish shreds could be peeled off almost everywhere, there being very little healthy structure anywhere to be seen. The arch of the aorta seemed rather dilated in its ascending portion, but no saccular dilatations were visible, no calcareous masses were present, and the middle coat seemed to be quite intact. The lungs were universally engorged, and the bronchial tubes full of mucus, but there was no consolidation. The kidneys were congested, and the cortical portion seemed to be rather mottled, as if in an early stage of fatty degeneration. The spleen and liver were normal.

Northumberland and Durham Medical Society. The annual meeting of this Society was held in the Library of the Newcastle-on-Tyne Infirmary on September 30th. The report of the Committee shows that the Society is in a flourishing condition. The number of members is 141. The work done during the session 1874–75, both in amount and quality, compares favourably with that of previous years. The following is a list of officers for the year 1875–76:—President: Mr. S. W. Broadbent. Vice-presidents: Dr. Arnison, Dr. Denham, Dr. Page, and Dr. Philipson. Secretary: Dr. Byrom Bramwell. Committee: Mr. H. E. Armstrong, Dr. L. Armstrong, Dr. G. T. Beatson, Dr. Burnup, Mr. Carr, Dr. Frain, Mr. G. B. Morgan, Mr. J. Hawthorn, and Mr. Russell.

Reviews and Notices of Books.

On Concussion of the Spine, Nervous Shock, and other Obscure Injuries of the Nervous System, in their Clinical and Medico-legal Aspects. By John Eric Erichsen, F.R.C.S. London: Longmans, Green, and Co. 1875.

In 1866 Mr. Erichsen published six lectures, which at the time attracted much attention, on certain obscure injuries of the nervous system, commonly met with as the result of shocks to the body received in collisions on railways. There were then to be found surgeons who went so far as to deny the existence of such a condition as that known as concussion of the spine. At the present time, however, although surgeons may differ as to the exact condition of a certain patient, or as to the prognosis of his case, we venture to state that none will be found who would deny that the gravest nervous affections may follow violent concussion of the body, even when at first the sufferer seemed to have escaped uninjured. This change of opinion, or rather increase of knowledge, is in a great measure due to the attention directed to the subject by Mr. Erichsen's former work. Such divergence of opinion as formerly existed concerning these injuries could only result from ignorance, and as these cases have so frequently given rise to litigation, no small discredit has been brought upon the profession by the public exposure of such extreme differences among medical men of equal eminence. It is therefore a matter for congratulation that such exhibitions are becoming more and more rare, and we think the thanks of the profession are due to Mr. Erichsen for the large share he has taken in preventing their occurrence by elucidating the nature of these obscure cases.

The present work consists of fourteen lectures, in which the six before published are included, not, however, without much alteration. Although a greatly increased experience has enabled Mr. Erichsen to speak much more positively as to the nature of the various conditions included under the name of concussion of the spine, he has in no essential point altered the views expressed in his former work.

The term "concussion of the spine," although undoubtedly somewhat vague, is useful in our present state of knowledge to indicate a certain condition of the spinal cord, and sometimes of the whole nervous centres, resulting from external violence, and "usually uncomplicated by any obvious lesion of the vertebral column." As Mr. Erichsen points out, it includes a variety of pathological conditions. Thus, the cord alone may suffer, or the damage may extend to the brain, and perhaps even to the sympathetic ganglia, and the injury may be followed slowly by hæmorrhage, by subacute and chronic inflammations, or by anæmia of the nervous centres. Exact pathological knowledge is still wanting as to all these conclusions, most of them being merely inferences from the symptoms. The reason of this is that few of the sufferers from concussion of the spine die directly from the effects of the injury, and those who never improve may drag on a miserable existence for years, and pass out of the hands of the surgeon who first saw them, and die at last under circumstances in which a post-mortem examination is not practicable. Thus, Mr. Erichsen says: "So rare are post-mortem examinations of these cases that no instance has occurred to me in hospital or in private practice in which I could obtain one, and, with one exception, I can find no record in the transactions of societies, or in the periodical literature of the day of any such instance." This one instance was under the care of Mr. Gore, of Bath, and was a most typical one in every respect. The patient walked from the train after the accident, but the symptoms of severe disease of the spinal cord set in gradually, and he died at the end of three years and a half. The cord was examined by Dr. Lockhart Clarke, who found signs of extensive chronic meningitis, and degenerative changes in the posterior white columns. With such meagre material as this before us, it is impossible for much to be said as to the pathology of these obscure cases, and Mr. Erichsen has of necessity made the present work almost purely clinical, and has illustrated it profusely with cases selected from his own practice. By a comparison of the symptoms of these cases with those which are recognised by all writers on diseases of the nervous system as being connected with and dependent upon chronic affections of the cord and its membranes, Mr. Erichsen clearly demonstrates the nature of the changes which follow a concussion of the spine, and may fairly be said to prove that, in at least a large proportion, chronic myelitis and meningitis are present. The greater part of the book is devoted to the consequences which may follow an apparently slight injury of the spine. We need not allude to the chapters on the symptoms, diagnosis, and treatment of those cases in which meningitis or myelitis form the most prominent feature further than to say that, although this part of the work is much amplified, and numerous illustrative cases have been added, it is in the main the same as was published in 1866, and is probably well known to our readers. In the present volume, however, Mr. Erichsen has added a chapter on the so-called "Spinal Anæmia, and especially Anæmia of the Posterior Columns of the Cord," as a condition following injuries of the spine. This condition in its extreme form is thus described:—

> "In the more intense cases of anæmia of the spinal cord there is paralysis more or less complete of sensation, and often quite complete of motion, in the lower extremities. Below a certain level in the dorso-lumbar region, and in the greater part, if not in the whole, the nervous system appears to be completely exhausted and its action almost entirely suspended.......The legs and feet are cold; there is no reflex sensibility or movement in them; they are not susceptible to the electric stimulus, either as regards muscular irritability or cutaneous sensibility. ...... Notwithstanding all this local exhaustion, it will be found that the sphincters are not paralysed, and the general health, though enfeebled, may be fairly good."

The condition is never fatal, and it is only by clinical inference that the idea as to the pathological condition has been arrived at. Mr. Erichsen considers it in many respects nearly allied to that condition which "for want of a better name we are apt to call hysteria," and which may also be developed as the result of severe nervous shock. These conditions are, moreover, undoubtedly aggravated by the mental worry of a lawsuit, and the patients frequently recover with great rapidity when they have received compensation for their injuries. But, as Mr. Erichsen justly points out, this does not by any means disprove the reality of the condition while it lasted. Speaking on this subject, he says:—

> "It is far too common a practice to treat this state either as being under the patient's control, or as being a condition of no material moment, inasmuch as it does not arise from permanent organic injury or disease. It is unjust as well as irrational to treat the condition as one of little moment. We only know it by its effects. We use the term hysteria to hide our ignorance of what the condition really consists. To me, I confess, the sight of a man of middle-age, previously strong and healthy, active in his business and in all the relations of life, rendered suddenly 'hysterical,' not merely for a few hours or days by some sudden and overwhelming calamity that may for the time break down his mental vigour, but continuously so for months, or even years, is a most melancholy spectacle, and is a condition that, to my mind, is an evidence of the infliction in some way of a serious and for the time disorganising injury of the nervous system, though happily that injury is not, in general, of a permanent nature, or attended by organic changes."

We fully agree with Mr. Erichsen in this view of the matter, and although the difficulties of detecting fraud and assessing damages in this class of cases must of necessity be greater than when some distinct organic lesion is present, we think a careful study of the excellent advice given by Mr. Erichsen will, in the vast majority of cases, prevent any error. The medico-legal aspects of these cases are treated of fully in a special lecture. Discrepancies of opinion as to diagnosis are now fortunately comparatively rare. It is in the prognosis that differences most frequently arise, and as long as lawyers attempt to obtain from medical men an exact statement as to the course of future events, such conflicts of opinion must and will occur. We cannot help thinking that these even are likely to be diminished by such a work as Mr. Erichsen's, containing as it does the honest and scientific conclusions from a very large experience, and illustrated as it is by numerous well recorded cases, which serve as guides to those whom fortune has not favoured with like opportunities.

Want of space prevents our noticing the interesting and philosophical lecture upon "Impairment of Vision, complicating Injuries of the Nervous System," and numerous other points of interest. Although, as the author points out repeatedly in this volume, the affections it treats of are by no means exclusively the result of railway accidents, yet these are infinitely the most frequent causes of them, and as such casualties are occurring daily in many parts of this country, no medical practitioner knows how soon he may be called upon to diagnose, treat, and afterwards be cross-examined upon such a case, and we can confidently state that under such circumstances he can have no better guide than Mr. Erichsen's work.

Etude Comparative des Diverses Méthodes de l'Exérèse. Par Ch. Monod. Paris: J. B. Baillière.

By the term "exeresis" the author means "ablation," so that this thesis refers to the different methods employed for the removal of new growths. He devotes but little space to the knife, the major part of the essay dealing with bloodless operations—e.g., the ligature and the écraseur, actual and galvanic cautery. Turning to the section devoted to the elastic ligature, as being the method most recently introduced (or rather revived) into practice, we find the author by no means sanguine as to its extended application, preferring, where the cutting operation is out of question, to employ the less prolonged and inconvenient operation by the écraseur, the merit of the introduction of which belongs to M. Chassaignac. He discusses at length the effect produced upon the several tissues by this instrument, and claims for it greater exemption from erysipelas and other surgical accidents than is afforded by the knife. The simple wire écraseur (or the *ligature extemporanée* of Maissonneuve) is less applicable from its smaller strength and its not so readily arresting hæmorrhage. After giving a historical and practical account of the various methods of cauterisation, the author concludes by summing up impartially in favour of one and all the methods of ablation here discussed in suitable cases, and dwells on the advantage of sometimes having recourse to a combination of the two. The essay is interesting as a careful historical compilation, but it cannot be said to contain any new facts.

The German Committee of the International Exhibition and Congress of Public Health and Means of Preserving Life, to be held in Brussels, held its first meeting at Berlin on Wednesday last, under the presidency of the Imperial Crown Prince.

THE LANCET.

LONDON: SATURDAY, OCTOBER 9, 1875.

The Introductory Addresses which annually usher in the winter session at our Medical Schools have again been delivered, and their public interest has once more invited the comments of our lay contemporaries. It must not be forgotten that the lecturer who delivers an "Introductory" addresses a double audience. He speaks to pupils, and he speaks to the public. The progress which has raised Medicine to the status of a public enterprise; which has brought it into intimate relation with the commonwealth and the national policy; which has developed it from a remedial agent dealing with the individual to a preventive service incorporated with the State; which has, so to speak, lifted it out of the category of personal interests and placed it in the circle of the social sciences, subsidiary only to Religion and Law; and which, therefore, as Dr. Barnes aptly put the case, invites or compels "those who have to give these addresses to select for their theme some of the wider and more general aspects of medicine," has not extinguished the claim of the student on the lecturer's primary attention. It is natural, and perhaps it is an advantage growing out of the existence of several schools in the metropolis, that the several gentlemen delivering introductory lectures may each take his own line; some treating the "opportunity" as especially available for the purpose of giving counsel to students, others as calling for something like a manifesto in the behalf of medicine and its professors, addressed to public opinion and designed to influence the Legislature and to promote the interests of the State.

A careful perusal of the addresses delivered in London on the 1st of October, 1875, will, we are convinced, satisfy any impartial reader that neither the "more general" nor the primary and personal objects of the "Introductory" have been neglected. The lecture by Dr. Robert Barnes at St. George's, for example, was a masterly and suggestive exposition of the salient points of interest arising out of "the relations of medicine to the public good." It abounds with forcible and instructive criticisms on the faults and anomalies of the position in which the science of health is left by the Legislature in its intimate relations with the law and its administrators. Not a few of the observations made by Dr. Barnes are deserving of the highest consideration by those with whom the redress of the grievances he points out—not personal or "professional," but public—practically rests. His description of legal precedent as too often "nothing more than error upon error crystallised by time," is worthy the attention of jurists, and suggests the only intelligible hypothesis upon which not a few of the wondrous contradictions and startling absurdities of medical jurisprudence can be understood or explained. The legal definition of the antiquated and meaningless phrase, "quick with child"; the unreasonable presumption of responsibility in the insane; the vague and arbitrary mode of taking scientific evidence in courts of justice, and "getting up" cases—which, as he pertinently remarks, has the effect of deterring "the best men from appearing as witnesses"—are topics upon which he is entitled to the hearing of all spirited and sagacious legislators: and by speaking out plainly he has done good service.

Dr. John Curnow, at King's College, on the other hand, dealt chiefly with the educational phase of the subject of the day, and it would be difficult to find a more complete and effective discourse on the progress and methods of medical inquiry and instruction. The vital importance of observation and demonstration, giving to each term a "concrete meaning," and the duty of carrying the study and "teaching in fatal cases from the bedside to the dead-house," are points upon which he strongly insisted, and which cannot be too strenuously urged. There are special reasons just now why the teachers in our schools should inculcate the universal necessity of a practical, direct, and inductive method of study. Pathological science is on its trial. It has to encounter formidable obstacles to progress in the parsimony of magistrates, the weakness of medical coroners, and the ignorance of lawyers. It is threatened with new perils by the spurious sentiment of humanity, which the excess of a few individual experimenters, with more zeal than knowledge, has unhappily produced. We entirely agree with Dr. Curnow, "that penal regulations should be demanded to restrict the advancement of any branch of scientific inquiry is surely to forget the lessons of history, and to ask us to return to the darkness and ignorance of the first fourteen centuries of our era, and which were only overcome when the 'giants of those days,' Descartes, Galileo, and our own Bacon and Newton, made the first onward step from the time of the early Greek and Roman philosophers, by applying physical methods to the investigation of natural phenomena, and by substituting the inductive mode of reasoning for that purely deductive plan which had alone been used in substantiating the truth of the mathematical sciences." It is no less true, with regard to the equally important and progressive inquiry in the departments of materia medica and therapeutics, that "one must shudder to think what vast harm may be done if this is checked by any legislative interference." As these topics of Dr. Curnow's address are strictly public and general, we trust they will elicit the sympathy of the lay press, and receive its support. To the student crossing the threshold of a scientific career we commend the address delivered at King's College as replete with information and advice of the highest value and moment.

Dr. Corfield, at University College, discoursed generally and eloquently on the value and importance of sanitary science; Dr. Stevenson at Guy's, Dr. Payne at St. Thomas's, Dr. Randall at St. Mary's, Mr. Lowne at Middlesex, and other lecturers, addressed themselves principally to the duties and privileges of the pupils among their audiences, and from the lips of each fell words of worth and wisdom. Dr. Payne struck a vein of great practical value when he defined the "true student" as distinguished from "a mere craftsman" by "the endeavour to cultivate his mind" no less than to acquire the technical knowledge of a profession; and Dr. RANDALL placed the prospects of the medical student on a legitimate basis, and applied the best incentive to a scientific course of study, when he indicated the probability that every medical practitioner would hereafter be actively and personally concerned in the work of "sanitation" and the preventive service of the State.

What an "Introductory" ought to be must, as we have hinted, be determined by the twofold aspect of the function to be discharged. As regards the student, there is the duty of directing his general method of study, explaining the curriculum required by the examining and licensing bodies, inculcating the necessity of preparatory knowledge and an earnest and persevering pursuit of the objects he proposes to attain, elucidating and enforcing the importance of information he may be tempted to think trivial, insisting on the indispensable value of clinical study, and exposing the danger and denouncing the dishonour of a recourse to the imposture of "cram." It is not less a duty to forecast the future, to stimulate the hope, and to excite the emulation of the student by pointing out the several careers of usefulness which lie open to him, and in either of which, with intelligence and industry, he may win an honourable reward. The adaptation of his particular studies to the end in view is also a theme of fitting gravity and moment. Just now there is, besides, the general obligation of directing all students to the special need of devoting attention to Sanitary science and the Preventive aspect of Medicine as an agent and a mission to search out and destroy the "seeds" and "causes" of disease. These topics, together with matters of interest peculiar to the school for which he speaks, must claim the lecturer's first attention, and may monopolise the whole of his time. The other aspect of the "Introductory" is that which constitutes the "opportunity." The professor enjoys an exceptional advantage—he addresses laymen, the friends of the new pupils, and he is tolerably sure of being reported and read by the outside world. He can speak to legislators, to social philosophers, to "authorities" whom on other occasions he may not hope to reach. It is fitting that full use should be made of the powers thus placed at the command of a lecturer chosen to act as the spokesman of his college or school. What he says will come with peculiar force, being spoken in the hearing and in the name of his faculty. This is an aspect of the "Introductory" which should not be disregarded either in the selection of a lecturer or in the treatment of his task. We think it does occasionally happen that the "opportunity" is not turned to the best advantage. An academic judgment on the politico-medical questions of the day is not easily pronounced, or obtained. It would have special weight in the Legislature and as a factor in the sum of public opinion. If there were sometimes previous deliberation and an understanding among the lecturers chosen to give the "Introductories" at the opening of the medical session, and a marked concord of opinion on public questions of policy was apparent, the delivery might be hailed as a new indication of professional thought, and it could scarcely fail to receive attention in the quarters at which it was aimed.

THE approaching election of examiners at the Royal College of Surgeons of England is of unusual interest, not only to students and teachers, but to every member of the College who is concerned in the educational advancement of his profession and of the College. For many years past we have strongly contended that the examiners in Anatomy and Physiology should be distinct and separate from the examiners in Surgery and Surgical Pathology; and although there has been at times a member of the Council or of the Board of Examiners that has favoured this scheme, it was not until last year that any active steps were taken to carry it into effect. It has, however, at last been decided that the separation shall take place, and it only remains now to arrange the preliminaries to give the decision effect. The report of the Committee that was formed to consider the question has not yet been received; but it is, we believe, confidently expected that the alteration will come into operation at the November examinations. The prospect of this innovation will influence very greatly the results of the ensuing election. The retiring examiners are Mr. HENRY HANCOCK, Mr. LE GROS CLARK, and Mr. SAVORY. The first-named gentleman has determined not to seek re-election; the other two are candidates for re-election, and will, doubtless, be returned to the Board of Examiners, as they deserve. Both Mr. LE GROS CLARK and Mr. SAVORY have proved themselves to be good examiners, even though the latter gentleman has the reputation of being somewhat severe on crammed pretenders. The interesting question is, therefore, who will succeed Mr. HANCOCK? There has been, we believe, for some years a strong desire on the part of many members of the Council that Mr. ERICHSEN, whose experience as a teacher and examiner has been very large, should undertake the duties of examiner at the College. But Mr. ERICHSEN, like some other members of the Council, has persistently declined to accept an examinership until the separation above referred to should be completed. If, therefore, the arrangements are sufficiently far advanced to ensure the separation of examiners in November, Mr. ERICHSEN will doubtless be elected as an examiner in Surgery and Surgical Pathology. Should this event take place —and there does not seem to be a likelihood of any other candidate appearing—it will augur well for the improved nature of the future examinations of the College. The test will doubtless henceforth become more uniform and certain, even though it be made somewhat more searching. This is exactly what is wanted. Neither teachers nor students complain of the difficulty of the examination for the Membership or the Fellowship, but they strongly object to the system of marking and the manner in which the examinations are conducted. We shall continue to live in hope. The College has been roused to a liveliness of action that twenty years ago would have been deemed impossible; and now that the thin end of the wedge of progress has been well inserted into the traditions of conservatism, it may not require much force to drive it home, and the College of Surgeons may yet take a proud position as the educational centre of British surgery.

◆

THE reassembling of the metropolitan Medical Societies after the summer recess is an event always looked forward to with considerable pleasure, not only by those who make it their duty to attend regularly at the meetings, but also by the wide circle outside the pale, to whom the columns devoted to the reports of the proceedings form not the least interesting or instructive portion of their weekly reading. Although, for some reason unknown to those not acquainted with the intimate working of these bodies, their annual general meetings are held in the early months of the year, when the operations of each are in full swing, yet, as a matter of fact, it is convenient to assume that their annual sessions begin in October—an assumption borne out by the publication of their Transactions at the commencement of the medical year. It may not, then, be without profit if we dwell a little upon the value of these Societies, as judged from the work they have already completed, and in view of the mission they have yet to fulfil.

This is an age of association and co-operation; it is the era of societies. With the growth of science, societies for its diffusion and the intercommunication of observed facts have sprung up all over the world. For although the rise and development of the chiefest of these—the Royal Society—dates back to the days of HARVEY, the oldest of the Societies devoted to medical science only recently completed its first century of existence. The Medical Society of London, although it is thus the oldest established, is content to occupy a modest position in the rank, but withal a most useful and honoured one. The names of LETTSOM and of FOTHERGILL are perpetuated in it by the annual lectures and prize essays that are associated with them; and, beyond these special features, the weekly meetings of the Society are productive of much sound and practical discussion. The work done by this Society may not be so striking or so ambitious as that performed by those which have sprung up one after another since it was founded, but it is none the less to be valued on that account, and its roll of members shows that it is popular and appreciated. It is much to be regretted that no Transactions of this Society have yet been published; for, without a doubt, in the history of a Society's proceedings there is reflected the history of that branch of knowledge to which it is devoted. Where, for example, can one trace better the growth of the science of pathology than in the volumes published annually by the Society that bears its name? The Transactions of the Pathological Society have justly obtained a world-wide fame, for they are the storehouse of pathological facts of a quarter of a century. The impetus given to minute research by the "cell-theory" of SCHLEIDEN and SCHWANN, the dethronement of humoralism, the rise and decline of a purely "cellular" pathology, the ever-increasing knowledge of the intimate nature of morbid growths, the wider insight gained into the mode of development of tubercle and cancer,—these and a host of other advances in this department of study, which go to make up the science of pathology as it is at the present day, are to be traced in these interesting volumes. For the sake of science, it is a matter of regret that the scheme proposed two years ago for the re-issue of the volumes of Transactions, which were out of print, fell through from want of sufficient support; and it is to be hoped that the Council will again endeavour to carry out an object which should be encouraged by all who value the study of pathology as the real basis of rational therapeutics.

The Royal Medical and Chirurgical Society has always held, and will of necessity always hold, the chief place among our Medical Societies. For, apart from the advantages possessed by its inestimable library, which can well compete with the collection in Lincoln's-inn-fields, its Transactions embody some of the most valuable researches in medicine and surgery that have ever been published. Here are to be found memoirs which have given to the world new discoveries, and which embody the labours of men who have risen to the highest rank, full of original thought and wide research. The names of ASTLEY COOPER, BRODIE, and ABERNETHY grace its earlier volumes, and their work has been fitly carried on by their successors. As a Society for discussion it is, however, far less numerously attended than those which have sprung up after it; unless the subject be one on which there is much division of opinion—as was the case last session when Mr. ACTON's paper on the working of the Contagious Diseases Acts was read. The right, too, which the Society possesses of determining whether a paper should be read and published is one which is jealously kept, and on some occasions strictly enforced.

On the remaining Societies—the Obstetrical, Clinical, and Harveian—we have left ourselves but little space to comment. The first-named has now for many years been doing much to advance obstetrical knowledge, and has done not a little to place this department of medicine on a firm and distinct basis. The Clinical Society supplied a need which the more formal meetings and long memoirs of the older body did not furnish, and its proceedings never fail to be productive of much that is interesting and valuable. It has had the advantage of having been presided over, during the seven years of its existence, by the foremost physicians and surgeons of the day; and the discussions that take place at its meetings are often the medium of much that is of the greatest value in therapeutics and clinical observation. The objects and advantages of the Harveian Society were recently pointed out in these columns, and to that statement we have nothing further to add. We can only express a hope that the coming sessions of all these bodies will be productive of as much benefit as has marked their career in the past, and that they will continue to flourish on the broad basis of sound facts, and not on the insecure foundation of doubtful theories.

◆

THE very gradual decline of the health of Dr. JOHN HUGHES BENNETT, and his gradual retirement from his work, serve to break the sense of loss which affects all those who knew him, and especially those who have had the good fortune to stand to him in the relation of pupils. Apart from our preparation for this loss, it would really have been felt to be very great. Opinion will perhaps be divided as to the kind of work in which BENNETT most excelled. Some will regard him chiefly as a physiologist; others will think most of his contributions to pathology; while a third class will think that the best work of his life was his therapeutical work. But all will allow that JOHN HUGHES BENNETT cannot with any justice be left out of the history of pathology, physiology, or medicine for the last thirty years at least. True, he will not in all of these regions take perhaps a first place, though in one or two of them he will hold a most enviable position.

There are two meritorious points in the life and work of Bennett which seem to us to stand out in marked relief. The first of these was his aptitude as a clinical teacher; the second, his most admirable contributions to the therapeutics of pneumonia and phthisis. All men who studied in Edinburgh while Bennett was Professor of the Institutes of Medicine and Professor of Clinical Medicine will admit that as a teacher he had no superior; and the subject in which as a teacher he perhaps had no equal was that of clinical medicine. They will remember the searching ordeal to which both patients and students were subjected in his clinical wards; and if occasionally there was a slight tendency in the teacher to bully the students who were examining a case, this fault has been long since forgotten in the memory of his great services. Dr. Bennett's teaching in clinical medicine was a decided feature of the University of Edinburgh, though it has probably now many imitators both in England and in America. The system is worthy of being shortly described. Those students who were members of his clinical class, and were willing to undertake the examination of cases in the wards, gave in their names. Certain cases were assigned to them to be examined before Dr. Bennett and the class. Everything had to be done and all opinions had to be expressed on the spot—of course in such language as was not inconsiderate to the patient; they had not only to be expressed, but justified; and as Dr. Bennett's powers of diagnosis were very high, and his views of treatment very decided, there was not infrequently a sharp discussion between him and his pupils. The student was required not only to examine parts which he might suppose to be at fault, but to examine in rotation all parts of the system—the nervous system, the circulatory, the urinary, the digestive, &c. Every part of the patient's system was ransacked. Nothing could well be overlooked in such an ordeal, and the state of both the patient and the student was well ascertained by it.

Dr. Bennett's merit as a physician equalled or exceeded his merit as a teacher. By this we do not mean to imply that he was ever popular as a physician. As a matter of fact we believe he was not. But his teaching and his practice together have been the principal elements in the great reform of the practice of physic which everybody perceives. Many may be disposed to think that Bennett's most valuable labours in therapeutics were his more recent ones; embracing severe and exact inquiries into the action of mercury, of taraxacum, of podophyllin, of medicines which antagonise each other, &c. And these labours have undoubtedly done much to improve both our knowledge and our practice. But, in our opinion, by far the most valuable therapeutical work of Dr. Bennett was his treatment of pneumonia and phthisis. These ailments are not only important in themselves, but they represent two great classes of disease—the one acute, and the other chronic. And Dr. Bennett, more than any other man, has contributed to reform the treatment of them, and to overthrow the views which had ruled medical men for centuries. Dr. Graves wished for no other epitaph than the three words—"He fed fevers." Dr. Hughes Bennett could not have a better than this: He reduced the mortality of uncomplicated pneumonia to *nil*. He demonstrated, not only the dispensableness, but the injuriousness of the antiphlogistic treatment which had ruled the best minds of the civilised world for ages. Doubtless other physicians were working in the same direction even before Bennett. But he devised a treatment of his own which has given most brilliant results, and he adhered to it and to the pathological views on which it was based so steadily and over so long a series of years as to establish its truth, and so largely revolutionise the practice of medicine in acute diseases. Coming now to the work of Dr. Bennett in regard to the treatment of phthisis,—what praise could we give too much to the physician who taught us to treat phthisis, not antiphlogistically, but with fresh air and cod-liver oil? It is admitted on all hands that this praise is due to Dr. Bennett. We have come to the end of our space, and yet we have not professed to assign the value of Dr. Bennett's work in physiology and in pathology. Frankly, we would admit that we do not think that in physiology he has done any very great original work. He was an excellent histologist, and, independent of the pathological views on which his great reforms in practice were based, he made several very important additions to our pathological knowledge—as of leucocythæmia, fibro-nucleated tumours, &c.; but he will be remembered chiefly as a clinical teacher and a bold and principal reformer in the practice of medicine.

◆

Hitherto the work of the Port Sanitary Authorities appointed under the Public Health Act of 1872 has been so largely concerned with special measures for the protection of the kingdom against cholera that there has been some danger lest the ordinary detailed duties contemplated in the establishment of these authorities should suffer. It is useful therefore to be reminded—now that the fear of any new extension of cholera to our shores is, for the moment at least, at an end—of the more abiding duties which it is the function of Port Sanitary Authorities to fulfil. A Report, recently published, of the medical officer of health for the port of London, Dr. Harry Leach, relating to sanitary work done under his supervision during the half-year ending June 30th, 1875, excellently serves as a reminder. Previous reports of Dr. Leach have, in the main, been devoted to questions concerning the regulation of the port of London with reference to epidemic diseases, especially cholera. The present Report relates the details of half a year's sanitary work in the port, in the absence of any prevailing epidemic malady. It deals simply with the inspection of shipping and of the port for the discovery of sanitary defects, and the remedying of such defects. Having none of those episodes of introduction of cholera or small-pox from foreign ports or local prevalence of scarlet fever which called for the greatest energy and the coolest thought of the authority and its officers to meet successfully, this Report may fail in interest for the cursory reader; but it is perhaps the most important of the several Reports written by Dr. Leach, as illustrating the every-day sanitary work of the port. The Report, in fact, relates to the fundamental sanitary work of the port, the execution of which will form the true gauge of its health-administration. The essential character of such work consists in continuous detailed inspection for the discovery of sanitary defects, and equally continuous minute care for securing the removal of such defects when found, and the prevention of their recurrence. It is remarkable how successfully Dr. HARRY LEACH has set afoot sanitary action in the port of London. During the half-year to which the Report under consideration refers, no less than 7705 vessels were inspected; and of these, 923 were cleansed, and 43 had various structural alterations made mainly for improved ventilation and lighting of the between-decks. This amount of inspectorial work, it must be understood, does not represent the whole amount of work of the kind that it was desirable should have been done in the port at the time, but simply such work as it was possible to do with the limited staff which Dr. LEACH at present possesses. As part of the regular inspectorial work, Dr. LEACH has instituted an examination of the drinking-water supplied to ships. In the present Report he gives the result of the examination of the water on board 64 ships, chiefly coming from foreign ports. Of these specimens, 4 were very bad, 25 bad, 19 doubtful, and only 16 good. The bad and doubtful waters were wholly from foreign ports; and now that international action is so much in the ascendant in social and sanitary matters, it may be suggested that the water-supply of shipping might well form a subject for such action.

It would appear that the visits of the sanitary officers to ships, and their suggestions, are most willingly received, and that owners and masters readily co-operate with them. While, on the one hand, this bears witness to the excellent temper and judgment with which the Sanitary Authority and its officers have been exercising their functions, it proves also that those functions meet with the approval of the persons who are most affected by their exercise. What has been effected in the port of London as to detailed sanitary work must be practicable and ought to be required in other ports.

◆

IN the last part of LUDWIG'S *Arbeiten* for 1875, which contains the results of work done in his laboratory during the preceding year, Mon. G. ASP gives a very careful and complete account of the Anatomy and Physiology of the Liver. He first describes the cells of the parenchyma of the liver, which, he observes, are often destitute of a nucleus, but frequently also contain one, and sometimes two nuclei. He gives a beautiful illustration of them, in which the nucleus appears as a disc, which is hazy towards the centre from the accumulation of granules; around the granules is a clear area, which is surrounded by a double contour line. In some instances all the cells of the liver seemed to be destitute of nuclei; whilst in other instances only particular parts of the liver contained non-nucleated cells. As the animal in which he first noticed this absence of nuclei in its hepatic cells had been fasting for many hours, he conceived that it might be connected with the period of digestion; and to test the accuracy of this view, he starved a rabbit for sixty hours, then removed a small portion of the liver through a small opening in the linea alba, and closed the wound. The animal was then abundantly fed, and shortly afterwards was killed by bleeding, and another portion of the liver examined; but the results did not support his theory, as non-nucleated as well as nucleated cells were found in both conditions—in the fasting as in the well-fed animal.

M. ASP enters into minute details of the distribution of the finest biliary ducts. These, it has now been satisfactorily ascertained, do not, as was formerly supposed, end in blind extremities outside the follicles, but penetrate into their interior in the form of fine canaliculi, which groove the surfaces of adjoining hepatic cells. The inter-insular biliary ducts are lined, according to ASP, by a fine columnar epithelium, which rests on a striated tissue composed of connective-tissue fibrils and flat cells with fusiform nuclei; but he has not been able to convince himself that the cells, as HEIDENHAIN supposed, are a form of unstriated muscular tissue. From these a number of fine capillaries are given off, which, dipping into the substance of the follicles, still possess a wall, and are not mere spaces between the cells. Their wall is composed exclusively of the above-mentioned flat cells with fusiform nuclei, the internal layer of columnar epithelium and the outer layer of connective tissue having gradually ceased. The precise mode in which the biliary capillaries terminate cannot be said to be accurately known. With all ordinary injecting fluids a plexus comes into view; but if they are injected with a solution of alkanin in oil of turpentine, or with an alcoholic solution of gamboge, very remarkable appearances are produced, which are only explicable upon the supposition that the solutions thus made penetrate into the interior of the hepatic cells by filtration, though this cannot be held to disprove the existence of a cell-wall.

ASP corroborates the statements made by MACGILLAVRY that the hepatic bloodvessels are surrounded by perivascular spaces, as he has been able to inject them by the method of puncture.

Annotations.

"Ne quid nimis."

"SACRIFICIAL" LITERATURE.

WE must apologise for applying the term "literature," in default of a more convenient word, to a class of writing which is in no sense literate. The *Cornhill Magazine*, a periodical which started on its career under the highest literary auspices, contains in its current number a conspicuous example of the composition to which we allude. The title chosen is "Sacrificial Medicine," and the avowed purpose of the writer—evidently a very remarkable person—is to show that "a large part of the medical science of all past ages proves that the doctors and their patients valued remedies *in proportion to the price to be paid for them*, either in money or in suffering; in short, adopted freely the Doctrine of Sacrifice as applied to Medicine." The italics and capitals are the author's. This general purpose is supplemented by a design to prove that the "inductive science" does not rule in the sick room even now, and that both doctors and patients retain their faith in "Sacrificial Medicine." We scarcely know which most deserves attention in the strange paper that, in some mysterious way, has found a place in the *Cornhill*, the ignorance and perverse ingenuity of the writer, or the innocence of the presiding censor who allowed it to pass into print. To begin with, the word "Sacrifice," although emphasised with a capital letter, and described as a "Doctrine," is employed exclusively in its most ordinary sense; the idea being made to include everything nasty or disagreeable to the taste of the person having recourse to a remedy. The operation of swallowing a dose of castor-oil or assafœtida is a "Sacrifice," and an exemplification of the "Doctrine." That this is the fact will be evident from the peroration, from which we quote the following elegant extract:—

"To Homœopathy (as to many another kind of heresy) we probably owe somewhat of the mitigation of orthodoxy; and children, noticing the busts of Hahnemann in the shop windows, may be properly taught to bless this great Deliverer who banished from the nursery those huge and hateful mugs of misery—black founts of so many infantine tears—mugs of sobs and sighs, and gasps and struggles unutterable, from one of which Madame Roland drew the first inspiration of that martyr spirit which led her onward to the guillotine, where she suffered herself to be whipped six times running sooner than swallow the abominable contents."

This is how the article ends, and it is a fair sample of the style throughout. It is, in brief, a compilation of all the filthy and absurd nostrums which, as everybody knows, were prescribed by the ecclesiastical and lay charlatans of the dark ages. The story has been told a hundred times—with humour, and it forms the staple of comic medical literature. It sometimes even finds a place in an "Introductory"! But it is taxing the credulity of those of our readers who have not seen this article to ask them to believe that a writer in an intelligent magazine actually treats the subject seriously, and adds to his monstrous folly the signal impudence of describing the authors of these pestilent nostrums as the Gulls and Thompsons of the period, with the implication that the distinguished practitioners with whose names he makes free are only a few removes from the same depths of ignorance. The argument, if we may be excused for a moment so describing it, stands thus: In 1621 somebody recommended for hiccup, "a beverage, of which the chief ingredient is the flesh of a mummy.... Cannibalism [therefore] survived in medicine, and was approved by the faculty in Italy as well as in England down to a recent date"—with the moral that doctors generally are knaves and savages. A parallel exploit of reasoning would be that, because in a certain dark period the sovereign believed in swimming witches, and archbishops superintended the burning of heretics, monarchy is a delusion and religion a snare. It would not be worth while to notice this marvel of stupidity, except as a curious product of the dull season in a quarter where rank weeds are not commonly cultivated, but that interspersed among the select stories there are assertions so grossly and flagrantly false that they call, not for contradiction—that would be a work of supererogation,—but for indignant exposure as offensive to decency and discreditable to the magazine in which they have been permitted to appear. The writer has the effrontery to ask: "Did anybody ever find a medical man, in view of a patient's straitened circumstances, telling his anxious friends that the remains of the last bottle of his physic would answer as well as a new one, or that they might readily change it by adding a few drops of some fresh ingredient, instead of ordering another six ounces from the chemist, to be set aside in its turn half-used to-morrow? Or (what is still more to the purpose) did anybody ever hear of a case wherein the physician summoned for consultation (possibly at enormous cost) has given his honest opinion that the regular medical attendant of the patient has mistaken his case, and that the treatment ought to be altogether reversed?" And so on in the same strain, with the unblushing imputation that the consulting physician jumps into his carriage after pocketing his fee, and cheerfully quits the house of mourning, "aware he is losing the patient's chance of recovery by his wrong treatment." We have no words in which to characterise the mendacious calumny of these outrageous falsehoods, and we think the responsible managers of the *Cornhill Magazine* owe it to the public and their own repute as honest men to tender the amplest apology for the insult to a laborious and liberal profession and an honourable class of practitioners, which their periodical contains. It is needless to say that no consulting physician would retain the respect of his colleagues a single moment if he did not instantly correct any error he might detect in a case to which he was "called in." This is always done, and while it is not only unnecessary, but would be cruel to the friends of a patient, to declaim against the treatment previously adopted in the extremely rare case where a general practitioner has "egregiously mistaken" the malady or its cure, it is the duty of the physician to remedy the error; and, though he cannot recall the past, he is responsible for the future. No sensible person needs to be told that this is the course pursued by every qualified medical man, and the contrary imputation can be damaging only to the magazine in which it appears. The title of the paper should have been that which we have set at the head of this rejoinder.

SALICYLATE OF SODA.

THE *Berliner Klin. Wochenschrift* contains an article on the effects of the salicylate of soda as an antifebrile, by Dr. Moeli, of the Rostock University Hospital. According to Kölbe, the salts of salicylic acid possess no antiseptic properties, which has been confirmed by other observers, their preserving effects on organic matter being derived from the amount of free acid in them and proportionate to it. The trials of this at present in Germany rather fashionable acid as an antifebrile induced the author to try the salt as such, the presence of alkali being indispensable for the absorption of the acid into the circulation, and soda appearing preferable to potassa. The solution of salicylate of soda (the acid is obtained from this salt by the wholesale manufacturing process, and therefore the latter is not dearer than the former) is of a brown colour and unpleasant taste; the addition of extract of glycyrrhiza or some wine taken with the dose is therefore recommended. From four to five grammes of the salt is the usual quantity given every other evening in cases where the larger doses of the sulphate of quinine (1·5 to 2·0 grammes) would be required. Several cases of typhoid fever (altogether seven), in which the drug was used without the cold bath or any other remedy, showed after each dose a constant decrease of temperature (from 2° to 3° C.), lasting over twenty-four hours, combined with a diminished frequency of pulse. An increase in the quantity of urine was not observed in the twenty-four cases of miscellaneous febrile diseases in which the salt had been administered. In half the number a profuse perspiration accompanied the fall of temperature, as has been recorded by Buss, after the use of salicylic acid. In some cases, however, the salt effected a decrease of body-heat from 40·4° to 37·0° C. without any sweating at all. In four cases sickness and vomiting compelled him to use the salt solution as an enema, after which a distinct fall of temperature followed, though of less importance than after an application by mouth. Subcutaneous injections must be made with a neutral solution of the salt to avoid severe pain which follows after injection of the acid. The author insists on the usefulness of salicylate of soda as an antifebrile remedy in comparison with the antiseptic but not antifebrile effect of benzoic acid. This chemical body in both forms, as derived from the urine of animals, as well as the acid made of the natural resin, possesses, according to the late experiments of Professors Salkowski and Fleck, antiseptic properties even in a higher degree than salicylic acid. The latter, however, acts undoubtedly as an effective antipyretic. Antiseptic treatment begins to assert its importance and success no less in medical cases than in surgery.

CHILDREN IN THE SILK TRADE.

General reforms frequently involve special hardships. The circumstances of a particular class may be exceptional, and a change conceived in the interest of the many may press inconveniently on a few. It does not, however, follow that the rule ought to be relaxed so as to meet the exception. Commonly the exception may be made to conform to the rule. A difficulty of this kind is just now engaging the attention of the Royal Commission on the Factory Acts. The Chamber of Commerce at Macclesfield has, it appears, represented to the Commission "that the circumstances under which the silk trade is carried on are of so exceptional a character as at least to justify the further suspension of the section of the Act relating to the employment of half-timers and full-timers." A deputation, headed by the Mayor of Macclesfield, has since enforced substantially the same plea. It is alleged that the effect of enforcing the full provision of the Act must be "to throw out of employment a large number of children whose labour is essential to the continuance of the Macclesfield silk trade." It is by no means clear that the health and happiness of the children concerned weigh as much in the estimation of the Chamber of Commerce as the prosperity of the trade it is desired to protect. This is only natural. But the Commissioners will do wisely to maintain the larger and national view, as distinguished from the narrower and local. It may be true, although the evidence is by no means conclusive, that "in order to learn the manipulation of silk perfectly, children should commence at an early age," but if this be the fact, some better mode of instruction or improved practice must be substituted for that which blocks the path of physical reform. The moral and physical health of the rising generation cannot be sacrificed to the Juggernaut of trade. The children of the poor are in a peculiar sense the children of the State, and it is bound to exercise a strong paternal guardianship. The problem which awaits solution is, if possible, to combine the conditions of health and education with the requirements of industry. In all cases where the support of the family depends in part on the remunerative labour of its younger members, the task of finding a satisfactory solution is, no doubt, embarrassing. But the provisions of the Factory Acts must be carried out in their entirety—that is, so far as the essential principle of relief is concerned,—and we trust the Chamber of Commerce will everywhere make it their chief concern to remove obstacles rather than cast stumbling-blocks in the way of progress. The health—the future prosperity—of the nation is deeply concerned in the issue of the struggle between the needs of trade and the necessities of the population. Taking the lowest standpoint, and looking to the interests of the race, it is abundantly evident that the young of the human species must be, as far as possible, emancipated from labour—that is, labour which stunts the growth of body and mind, and issues in the development of an adult feeble in form, incapable of the higher functions of life, and reproducing in its kind a progeny impoverished by its own blighted growth, and in time contributing to a degeneracy which must end in national weakness and individual want. It is eminently short-sighted to oppose measures conducing to the improvement of the race, and it will hereafter be found a fatuous policy to sap the root from which prosperity must spring.

THE "DAILY TELEGRAPH" ON STREET ICES.

A few warning and suggestive remarks which appeared in The Lancet last week, on the subject of "Street Ices," have furnished a clever but hard-pressed leader-writer in the *Daily Telegraph* with matter for a column of agreeable banter. The didactic portion of his discourse is apparently designed to teach that ices are not bad in themselves, but injurious only when taken at ill-chosen times—for example, in the middle or immediately at the close of a meal. There is not, perhaps, much to which exception need be taken in this statement; but we offered no opinion on the expediency of eating ices—we only laid down that "cooling drinks and frozen eatables need to be especially pure and good in themselves," and our contemporary is obliging enough to confess that he thoroughly agrees with us. The objection we took to street ices was that they were not as a rule "pure and good." The *Daily Telegraph* is greatly scandalised by our remark that "the common street ice is a concoction of dirt and indigestibility." We are reminded that an ice is not concocted, or, as our contemporary curiously puts it, "subjected to any process of 'coction' or cooking whatsoever." We are also informed "that 'indigestibility' is not a tangible substance, susceptible of being made into a decoction by the addition of dirt." This is laborious, but it is not very intelligent humour. It is worthy of the journal which not long ago described "the shrine of Nike Aptera's Wingless Victory"; but it is not worth answering, further than to remark that "concoction" and "decoction" are different words, having diverse significations, commonly received and generally understood. If our contemporary will take the trouble—as we did before drawing attention to the subject—to examine the ices sold in the streets by hawkers with barrows, he will find they are not so simple as he seems to suppose. The gaudy colouring alone should have suggested reflections which might have warned a clever but unskilled writer from taking up the cudgels in defence of a danger he evidently does not realise and is not in a position to understand. We repeat, these cheap ices should be regarded with suspicion, and if the working classes have money to spare for such luxuries, they will do better to spend it in wholesome food.

PHOSPHATURIA.

The attempt of Dr. Prout to establish a "phosphatic diathesis," based upon the tendency to the deposition of earthy phosphates in the urine, was unsuccessful, and met with determined opposition on the part of other observers highly experienced in the pathological indications of the urine; and since Dr. Bence Jones showed in his "Animal Chemistry" that the quantity of phosphatic deposit depended almost wholly upon the alkalinity of the urine, the idea of there being such a constitutional state as "phosphaturia" has fallen into abeyance, much as the kindred "oxaluria" has. In fact, excess of these constituents has more properly been regarded as symptomatic of derangements in nutrition, and not as a primary disorder leading to grave changes in the organism at large. A monograph has recently been published by M. J. Teissier, of Lyons, entitled "De la Phosphaturie à forme Diabétique," the object of which is to show that there does exist a grave constitutional state signalised by polyuria, wasting, and other symptoms of diabetes without the presence of sugar in the urine, but with a large excess of earthy phosphates. The normal quantity of phosphates excreted in twenty-four hours is about ten to twenty grains, but in this affection the salt has been observed to reach from four to ten times that amount. The cases of phosphatic polyuria were first observed by M. Teissier *père*, two or three years ago, in which there were the constitutional symptoms of diabetes, with the passage of large quantities of urine, but no sugar; the specific gravity being low (about 1012), and the amount of phosphates being largely in excess of the normal. In one such case, in which there was as much as 450 grains excreted per diem, the patient was attacked with neuro-retinitis and subretinal œdema, *followed* by albuminuria. The albuminuria diminished, but the phosphaturia continued, so that the case is compared to albuminuria complicating diabetes. Another case is given in which traces of sugar as well as of albumen occurred in the course of the affection, but the excretion of phosphates persisted. The author inquires whether "diabetes insipidus" may not be phosphatic polyuria. It is worthy of note that Dr. Dickinson, in his recent work on Diabetes, records excess of phosphates in the insipid form of that disease.

M. Teissier further points out, in confirmation of his view (which he expresses very cautiously), that there may be a "phosphatic polyuria resembling diabetes," that this condition leads to grave disturbances of nutrition, notably cataract, in the same manner that diabetes does. He has analysed the urine in many cases of cataract, and in some has found excess of phosphates in the urine. He gives an outline of three cases of double cataract in which phosphaturia was present, in all of which operative interference led to ill results, and points out that in none of these cases was there any disease of the osseous or nervous system, while the fact of the cataract being double indicated some diathetic state. He affords no explanation as to the starting point of the affection, but contents himself with propounding the question that it may be due to over-acidity of the blood favouring the solution of phosphates in the economy, or to a morbid activity of the nervous system by which more phosphates are used up in the nutrition of the nervous centres.

GLASGOW CONSERVANCY.

THE medical officer of health for Glasgow, Dr. James B. Russell, has lately submitted to the Committee of Health of that city a very interesting memorandum on ashpits and privies. It is a history of the ashpit and privy question in Glasgow, and affords an instructive illustration of the difficulties which beset the carrying out of the simplest sanitary arrangements among local representative bodies. Until very recent years Glasgow ashpits and privies had an exceedingly unsavoury reputation. In 1863 the Committee of Health took the question in hand, and instructed Dr. Gairdner, the then medical officer of health, and Mr. Carrick, the master of works, to arrange as to the best principles on which ashpits should be constructed in various parts of the city. As the result of this instruction, the Committee were in effect advised to limit the size of the ashpits and privy vaults, and to cleanse them daily. Thereupon the inspector of cleansing, who appears to represent a different department, is called upon to fix the periods for the removal of the contents of the ashpits and privies, and he lays down the rule of practice that all box privies and small ashpits should be cleansed daily, and other ashpits and privies at an interval to be governed by their situation and the number of people using them. Having started upon this course for amending privy and ashpit nuisance, ten years pass, during which the practice of cleansing does not accord with the principles laid down for its performance, and in which the cleansing department of the municipal government is so conducted that the sanitary advantages to be obtained from structural improvements of privies and ashpits by the health department were not secured. In other words, the operations of the cleansing department were not governed by the sanitary needs of the city as represented by the health department, but by other considerations, so-called economic, and the latter committee found its most formidable and persistent opponent in doing its duties with respect to excremental nuisances in the very department which it might be presumed was primarily established to facilitate their execution. This is not an uncommon spectacle, we believe, among municipal committees this side of the Tweed. Manchester not long ago blundered in this way, but, if we mistake not, this city has now put the cleansing of its privies and ashpits under the control of its Health Committee, so that the cleansing may be in accord with structural improvements of the receptacle. Glasgow cannot well afford to do otherwise.

PERMISSIVE SHAM-SANITATION AND THE DEATH-RATE IN HULL.

WITH regard to population, Hull is about the tenth English town, while as a port it only yields in importance to London, Liverpool, and Bristol. It may be imagined, therefore, that the health of this large town, the population of which the Registrar-General estimates at 133,932 persons, is a matter of somewhat more than local interest. We therefore feel bound to call attention, first to the value apparently placed upon the health of the town by the Town Council or Urban Sanitary Authority of Hull, and secondly to the sanitary condition of the town as judged by its recent mortality statistics.

It appears from an apparently authentic list of provincial medical officers of health that the salary assigned to the medical officer of health of Hull, who also fills the post of port inspector, is £20 *per annum and fees!* That the post of medical officer of health of the town and port of Hull should be held by any medical practitioner must signify that a large proportion of the duties appertaining to such an appointment remain unperformed. The amount of fees is left to the imagination, but it is improbable that they are considerable. We are therefore forced to the conclusion that the Urban Sanitary Authority of Hull either considers that there is very little sanitary work to be done in the town, or desires that it should be done and not paid for, or is content that the necessary work should be left undone.

As regards the sanitary condition of the town, let us look at recent statistics on the subject. During the thirteen weeks ending 2nd inst., according to the Registrar-General's Weekly Returns, the annual death-rate in Hull was equal to 30·1 per 1000, and exceeded by 26 per cent. the average rate in eighteen of the largest English towns. The rate in Hull in the corresponding period of 1873 and 1874 did not exceed 27·5 and 26·7 per 1000. The death-rate during the past summer quarter in Hull from the seven principal zymotic or preventable diseases was equal to 9·6 per 1000, and exceeded by 48 per cent. the average zymotic rate in the eighteen towns. One more fact. The rate of infant mortality, measured by the proportion of deaths under one year to births registered, was 288 per 1000 in Hull last quarter, and was 30 per cent. in excess of the average rate of infant mortality in the eighteen towns. This comparison could be carried further with similar results. Judged by all the various tests supplied by the manipulation of the mortality statistics of Hull, the sanitary condition of this town is most unsatisfactory, even measured by the low average standard of health prevailing in our eighteen largest English towns. The existence of such a palpable sanitary sham as a nominal medical officer of health for this town and port at an annual salary of "£20 and fees," affords one of the most powerful arguments against the present system of permissive sanitation, a system which is apparently powerless to interfere with the waste of life now going on in Hull.

DISTENSION OF THE URINARY BLADDER MISTAKEN FOR AN OVARIAN CYST.

ONE of the most mortifying mistakes in diagnosis that can be made, and yet one that is by no means infrequent, is that in which an abnormally distended bladder is thought to be an abdominal tumour of importance. Misled by the occurrence of apparently free discharge of urine, the clinical observer has been known to diagnose a pregnant uterus when there was only hysterical retention of urine, and when the timely use of the catheter has caused the disappearance of the tumour and the pregnancy at once. Dr. Murchison records a remarkable case of enlargement of the abdomen in an elderly male, which was justifiably believed to be hydatid tumour of the liver, but which, on tapping, yielded twenty-four pints of urine. Another case has been recorded in *Le Progrès Médical* (May 15th), which is highly instructive. The patient was a female, thirty-two years of age, in whom menstruation had ceased for three months previous to her admission into Lariboisière Hospital, under M. Jaccoud; but there were no definite signs of pregnancy. Ten days before admission she experienced pain in the abdomen, which rapidly began to enlarge, and was soon followed by œdema of the lower extremities and genitals. There was a tumour in the median line, occupying the hypogastric and umbilical regions, reaching to four finger-breadths above the umbilicus, descending below into the pelvis. The cervix uteri was out of reach when vaginal examination was performed; and at first the opinion was that the tumour was ovarian, which was replaced by the hypothesis that it was a distended bladder, from its rapid growth, the pain at its onset, and the difficulty experienced in micturition. Catheterism yielded about a pint and a half of urine, and the bladder was thought to be completely evacuated. M. Jaccoud deferring a complete examination until the next day, the patient was seized in the night with dyspnœa, to relieve which the tumour was aspirated, and nearly eight pints of urine were drawn off, the last portions being blood-tinged. Before the operation the catheter had been employed, so as to be sure that the bladder was empty. Death occurred in six hours, the post-mortem examination showing a uterus between the third and fourth months of pregnancy, and great dilatation of the bladder and ureters. The seat of puncture was sought for in the walls of the bladder without success. No mention is made of the reason why catheterism failed to draw off all the urine.

SCURVY.

THE *Shipping Gazette* of the 29th ult. contains a special account of the official inquiry held at San Francisco on the 3rd ult. as to an outbreak of scurvy that occurred on board the ship *Bremen* on the outward passage from Liverpool. From this it appears that the ship was chiefly manned by coloured seamen, that the passage occupied 192 days, that many of the crew refused to take the lime-juice, although double allowances were served out to them, that fresh messes of vegetables were served out during part of the passage twice a week, and that in cold latitudes most of the watch were allowed to remain below. It appears also that many of the crew were unhealthy, or, at all events, unsound when they sailed from Liverpool, for one died of what is recorded as consumption about a fortnight after the commencement of the voyage, another man had fever of some kind, a third was down with dysentery, two others met with accidents, and a sixth, having chest pains, was treated, among other things, with mustard plasters before (as we hope) scurvy had commenced. The crew were short of bedclothing, but although the ship was manned by a Lascar crew no extra blankets were taken, and no canvas was served out to keep the men warm. The steward refused to show the books from which he quoted the quantities of stores served out, and the captain, although all this miserable sickness prevailed, did not think of putting into Honolulu or any port because "he had been twenty-eight years a shipmaster, and never put into any port but his destined port." The court was composed of the consul, three ship captains, and Lloyd's agent, but, strangely enough, there was no medical member. The captain's certificate was returned to him with the remark that he had failed to exercise the discretionary power vested in him as to running for another port, Honolulu being to leeward, and, with the trade winds, only six or seven days' sail. This, with a court wholly composed of nautical men, is the nautical aspect of the question. The sanitary aspect shows that all crews, and particularly coloured crews, should be examined before the ship sails, that with such men a special store of warm clothes and bedding should be provided. For it is really of more importance to Lascars than good food, that clothing suitable for coloured men should be supplied. It is not within our experience that coloured seamen, whether East Indians or Africans, as a rule refuse lime-juice; but the evidence does not show clearly whether the lime-juice was given out day by day, and mixed properly according to the terms of the Act; and the conduct of the steward in refusing to show his books is of itself very suspicious. Anyhow it is a disgrace to the present generation that any British ship should be thus decimated with scurvy.

A MAGISTRATE AND A MEDICAL WITNESS.

THE following report by *The Times* on Saturday last of the proceedings in a police case must be given literally:—

> "Patrick Barrow, labourer, was charged at Westminster, on remand, with an indecent assault upon Bridget Cronin, aged nine. Mr. Arthur Price, house-surgeon of Westminster Hospital, was put into the witness-box. Mr. Arnold, the sitting magistrate, asked him how it was that he had refused to inform a constable whether he had any evidence to give for the prosecution, when interrogated by the constable upon the matter? Mr. Price replied that he was not in the habit of giving evidence to police constables, but was at the service of the Court if required to give evidence in the usual way. Mr. Arnold thereupon intimated that the interrogation was by his desire, censured Mr. Price for his reticence to the constable, and asked him if he had any evidence to give for the prosecution. Mr. Price replied that such evidence as he could give would be in favour of the prisoner. Mr. Arnold then bade him stand down, and said that he 'did not require his services.' Barrow, who strongly protested his innocence, was then committed for trial."

The above report would be incredible if it appeared in any less trustworthy authority. It is disturbing to think that under the very shadow of the Houses of Parliament a magistrate should seek evidence in such a loose fashion, and instead of himself hearing a medical witness's testimony in the ordinary way, should make the reception of it depend on a policeman's report as to whether it was likely to be one-sided. Mr. Arthur Price was perfectly right in refusing to give his evidence to a police constable. Indeed, he would have acted very wrongly had he not so refused. If this is the habit of police-courts, or of the Westminster police-court, the less it is countenanced by medical witnesses the better. Our contemporary the *Examiner* devotes a leader to the incident, and it is most justly indignant at the conduct of the police magistrate. The prisoner has been since tried at the Middlesex Sessions and acquitted. There is every reason to believe that he would have been acquitted at the police-court if the evidence in his favour had not been disallowed.

THE MEDICAL EDUCATION OF WOMEN.

THE medical women question has received a speedy and decisive answer at Birmingham. It will be remembered that a deputation of women's rights advocates recently waited upon the Council of Queen's College and urged the desirability of making provision for the education of female medical students, backing up their suit with the hint that to admit female students would tend to popularise the College. It was very prudently remarked that the assent of the hospital authorities should be obtained before the scheme could be entertained. At length the Council have unanimously resolved to decline to admit women students. The Council were induced to come to this determination in consequence of the result of the joint action of the professors and of the medical officers of the General and Queen's Hospitals, to which we called attention last week, and from a subsequent resolution of the professors, carried by a majority of nine to three votes, that they (the professors) could not undertake the medical instruction of women students in Queen's College.

It would appear, therefore, that another door has been closed against the well-meaning but misguided females who are afflicted with the delusion that the arduous and responsible labours of medical life are not properly performed by members of the sterner sex. If we could but feel that the matter will end here, what a relief! But sooner or later other attempts will be made, at Birmingham or elsewhere, and it may happen that some aspiring institution desirous of "popularising" itself will in a moment of weakness accept the seductive offer, and the female aspirants to medical practice find another home.

THE DYSMENORRHŒAL MEMBRANE.

DR. P. FINKLER, of Kiew, has examined seven specimens of dysmenorrhœal membrane obtained from four patients. One of these was under observation in the hospital for three months. During that period she menstruated three times, and passed a membrane on each occasion. Dr. Finkler believes that the membrane is the mucous membrane of the uterus, inclusive of the blind extremities of the glands, but that in some cases the deeper layer of the membrane and the terminations of the glands remain in the uterus. The structure of the seven membranes examined was essentially the same, but with varying proportions of blood, round cells, and epithelium, and similar to what had been described before as the structure of the uterine mucosa during the early part of menstruation. The names "apoplectic," "villous," "inflammatory," which have been given to different states of the membrane by different authors, depend on the quantity of blood, and granulation or round cells, found in the tissue; the villous character of the membrane depends on strings of fibrine which, in some cases, appear attached to its inner surface. The membrane is the product of disease, and not of impregnation and abortion, as was shown by the case referred to above. Nor is it the product of the increased physiological action which takes place in the generative organs periodically; but it is the result of a pathological condition which is to be looked for in the character of its elements, in the great accumulation of granulation cells, many homogeneous, others granular, some nucleated; in the blood and fibrine found in the tissue; in the epithelium swollen, glistening, or lost in the flocculent outer surface of the membrane; persistence of the disease, its recurrence after cold, abortion, labour, acute inflammation of the uterus; the condition of the uterus itself, its false position, and abundant flow of mucus (often with acid reaction) from its cavity. All the membranes examined gave the amyloid reaction with iodine and sulphuric acid, and Dr. Finkler thinks this is probably the real pathological condition. The cause of the separation of the membrane he finds in the accumulation of granulation cells in the mucous and submucous tissue, and in the flow of blood, which in some cases takes place into the whole of the mucous membrane, and in others only into the deepest layer of it; in consequence of these two forces the mucous membrane becomes detached, acts like a foreign body, and excites uterine contractions.

THE KINGSTON GUARDIANS AND THEIR MEDICAL OFFICER.

WE are glad to observe that a most ungenerous attempt to oust the medical officer of the Kingston Union, Mr. Harris, from a position he has worthily held for many years has been frustrated by the good sense of the majority of the board of guardians, before whom the case was lately brought. The very utmost that could be urged against Mr. Harris was that he had committed an error of judgment in the treatment of a lunatic patient. "He delegated power to the nurse to use the strait-jacket" was the extreme charge that his principal accuser brought against him. Colonel Cole should consider the ruinous penalty which the adoption of his motion would have brought on a professional man. The loss of the appointment itself was a very little matter, but the dismissal would have attached a stigma on Mr. Harris as cruel as it was undeserved. With the exception of a clerical member of the board, Col. Cole found no one to support him in his ill-advised endeavour; the rest showed themselves unmistakably on the side of reason and justice, and denounced the proposal as "unchristian," and as "an unparalleled piece of effrontery," which is precisely the opinion we have of the attempt. Naturally the profession in the district received a rude shock on becoming acquainted with these proceedings. Mr. Harris's professional brethren lost no time in drawing up an address of sympathy to him, which has already received the signatures of nearly thirty medical men. Meanwhile the affront is likely to recoil on the head of the assailant.

A NEW YORKSHIRE INLAND WATERING-PLACE.

A Local Government Board inspector recently held an inquiry at Hovingham, near Malton, respecting an application from the Malton rural sanitary authority for power to borrow £1500, to be expended in the improvement of the drainage and water-supply of this village, which in a local paper is described as "a popular little inland watering place." It was stated that a considerable number of the villagers were opposed to the expenditure of this money, and that they had memorialised the inspector against the scheme; but at the meeting, which was well attended by the ratepayers, the opposition was but slightly represented. After considerable discussion, the inquiry was adjourned for amendments of the scheme, both as regards drainage and water-supply. The inspector suggested that the drainage-plan should be so altered as to carry the sewage further from the village, and to admit of its application to the land, or, if it be necessary, to empty it into the beck which runs through the village, to remove the point of its discharge lower down than the scheme proposed. With reference to the water-supply, the inquiry was postponed, in order to obtain analyses both of the water from the proposed source and from the wells at present in use. It would appear that the popularity of Hovingham as a watering-place must be of very recent date, as the population of the township of that name declined from 608 in 1861, to 587 in 1871. It augurs well, however, for the future prospects of the watering-place that its drainage and water-supply should thus early be dealt with. In most of the older watering-places these matters were too often left to look after themselves, until neglect created an absolute nuisance.

THE MIDDLESEX HOSPITAL.

The usual dinner of the students and friends of the Middlesex Hospital, held at the opening of the medical session, took place at St. James's Hall on October 1st, Mr. Campbell De Morgan presiding. The attendance was large and the evening was a very successful one, the speeches being remarkable for their good taste and feeling. The chairman, in proposing the toast of the Middlesex Hospital Medical College, remarked upon the present condition of the institution as a favourable contrast to former years. He remembered how that one session the total number of entries amounted to three and a half! The toast was coupled with the name of Dr. Greenhow, the Treasurer of the College, to whose unremitting energy and discretion much of the present position of the school is owing.

During the recess extensive alterations in the way of enlargement and improvement of the school-buildings have been undertaken. Mr. Foster, of Sidney Sussex College, Cambridge, has succeeded Mr. Heisch in the chair of Chemistry at the hospital.

"A COLONY OF LUNATICS."

At Gheel, a village in Belgium, there is a colony of lunatics under the care of Dr. Bulckens, and during the recent Medical Congress at Brussels it was visited by about forty members, who were greatly interested in what they saw and heard of the condition of these unfortunate people. The lunatics, who number about 1300 of both sexes, are not kept in an asylum, but board and lodge with the inhabitants. The patients come from all countries, and belong to all ranks of society, being accommodated according to their means. The more dangerous lunatics are placed in outlying isolated houses. The inhabitants are all more or less engaged in the surveillance of those who are quartered upon them. There is a depôt asylum and hospital to which cases of violence and urgent illness are sent. It has been suggested that the system would work well elsewhere. It would be interesting to learn whether this constant association with the demented tends to induce any form of mental deterioration among the villagers of Gheel.

OBSTETRIC NURSES.

It seems to be too generally fancied that any nurse will do for a lying-in woman. We see instances from time to time of the mischievousness of this delusion, lying-in patients drifting into bad conditions from the ignorance or the inefficiency of the nurse. A sad case has just occurred at Wrexham, in which a nurse of seventy years was awoke at six in the morning after a whole night's heavy sleep. She took it for granted that what her mistress wanted was a draught which had been prescribed. Without having any conversation with her, she took up an aconite liniment instead of the draught and gave it to her unfortunate mistress, who shortly afterwards died with all the symptoms of aconite poisoning. The nurse admitted frankly her mistake, and made no excuse for it. She was evidently too old for the work, and too exhausted to use her wits in the night. Even if the bottle had been marked "poison," it is quite probable that the same sleepy error might have been committed.

OUTBREAK OF ENTERIC FEVER ON BOARD THE "CORNWALL" SCHOOL-SHIP.

During the past week nineteen cases of enteric fever have been admitted into the Seamen's Hospital, Greenwich, from the *Cornwall* school-ship stationed off Purfleet. These make the number of cases received during the past fortnight amount to twenty, the first case having been admitted September 21st. The water employed on board the *Cornwall* is brought off daily by the ship's launch from a well or reservoir situate near the river. As the cases of enteric fever have occurred so simultaneously, we would suggest that the water-supply has probably become contaminated. At all events this should be the first step in the inquiry, which we hope will be of a most searching character. We understand that a case of enteric fever has also occurred on board the *Warspite*.

WORCESTER INFIRMARY.

We should be sorry to see the Executive Committee extricated from the difficulties which they have brought themselves into by medical men rushing to fill the vacancies created. At present there is only one physician to do the work. Two others have applied to fill the vacancy: one, Dr. Hunt, of Birmingham; the other, Dr. Woodward, of Worcester. Dr. Hunt, on hearing the circumstances which had led to the vacancy, withdrew his application. The Executive Committee have rejected a motion to call a meeting of governors to decide the question in dispute. They cannot be congratulated on the spirit they display in this controversy, which, if not satisfactorily terminated, may prove more disastrous to the institution than they think.

THE PUBLIC HEALTH ACT, 1875.

The Local Government Board has issued a circular to local authorities descriptive of the Public Health Act, 1875, and explanatory of the various amendments of the sanitary laws contained in the Act. The work of consolidation necessitated numerous minute amendments to remove obscurities in the Acts consolidated and to harmonise their provisions. Advantage was also taken to introduce certain amendments extending the powers and obligations of sanitary authorities. The circular describes in detail the different amendments, and forms a very important appendix to the Act of 1875.

MORTUARIES.

At the last meeting of the Metropolitan Board of Works a memorial from the Strand District Board was read, setting forth that owing to the want of mortuaries for the reception of the dead before burial the health of the living was greatly endangered. In many crowded localities it was difficult to obtain sites without compulsory powers. The memorialists, therefore, prayed the Board to introduce a Bill into Parliament conferring upon vestries and district boards compulsory powers for the purchase of sites for mortuaries. The memorial was referred to a special committee for report. Dr. Joseph Rogers has been most active in this matter, and whatever may be the issue of the present application, he deserves great credit for his well-directed efforts.

"SIN AND DIARRHŒA."

The Wednesfield Local Board have been perplexing themselves with the knotty question of the significance of epidemic diarrhœa. The ordinary views as to its relation to bad water, faulty drainage, and the like found some supporters. Mr. Wadley—described as a stout, robust gentleman—could not understand all the fuss made nowadays about the water question. When he was a young man he used to drink nothing but river water. He used take a cup and drink water from the side of a 'good jed dog' in the river." (Loud laughter.) Mr. Cooper cut the knot. He said that sin had brought disease into the world, and the Almighty permitted the outbreak of diarrhœa in their midst; neither doctors nor anyone else could prevent it. Mr. Cooper is not far wrong. Sin has much to do with diarrhœa, especially municipal sin, which permits a population to drink sewage, and then coolly satisfies itself with referring the judgment to the Almighty.

BOARD SCHOOLS AND SCARLET FEVER.

"A Medical Man," in a letter to the *Standard*, justly exposes the ignorance of a School Board visitor, who insisted on a child who had suffered from scarlet fever ten days, but who was feeling pretty well, returning to school. The writer says he has "often" been horrified at such indiscretions. This is one of the many ways in which children disseminate disease. This child was doubtless in an actively infectious state, and would be for a month or more after her return. The Board should take this matter into consideration. It is the opinion of the best judges that two or three months must elapse before a scarlet fever patient ceases to be capable of conveying the disease.

The annual St. Bartholomew's dinner was held on Friday, the 1st inst., in the great hall of the hospital, under the presidency of Professor Humphry, of Cambridge. The old students and visitors mustered more largely than on any previous occasion, upwards of 120 being present, and the company included Sir Sydney Waterlow (treasurer of the hospital), Drs. Carpenter, Acland, West, Black, F. J. Farre, Stenhouse, and Monro, Sir James Paget, Professor Abel, Mr. Savory, Mr. T. H. Hills, Mr. Holden, Dr. Andrew, Mr. W. H. Cross, and many others connected with this celebrated hospital and school. The duties of chairman were most ably performed by Dr. Humphry; Dr. Acland, Sir James Paget, and Dr. West were specially happy in their speeches, and the prandial and other arrangements of the evening were eminently successful, thanks to the administrative skill and genial activity of Mr. Langton.

A humane and wise regulation now prescribes that at our criminal lunatic asylums a separation should be made between two classes of inmates. Dr. Orange, the able medical superintendent of the Broadmoor Criminal Lunatic Asylum, shows in a recent report how beneficially the plan may be made to work. Those who belong to the class detained during Her Majesty's pleasure are to a great extent persons who have acquitted themselves honestly in their callings up to the period when they have become afflicted with insanity, and who then, under the influence of some delusion, commit a crime. Those, on the other hand, who have become insane whilst undergoing penal servitude are widely different. They are for the most part habitual criminals inured to crime and vice. It is only of late that an attempt has been made to separate these two classes, and already it has proved effectual in reducing insubordination and disorder.

The friends and admirers of the late Sir John Gray have determined to erect a suitable monument to his memory, in testimony of his ability, energy, and perseverance. To him the citizens of Dublin are mainly indebted for the pure water they at present possess. The deceased in early life practised as a surgeon, and to the sanitary and scientific knowledge thus acquired may be attributed the successful carrying out of the Vartry water-system.

The Artisans' Dwellings Act promises to work well. As is known, it places great power in the hands of medical officers of health—power which, however, we are quite confident will never be misused. The process of demolishing courts and alleys unfit for human habitation may be said to have commenced. The initiative was taken some time back in one of the eastern districts of London, and we now learn that Dr. Tidy, the medical officer of health for Islington, has, within the last few days, submitted to the Sanitary Committee of the Vestry a list of places in the parish to which the Act should be applied. The recommendations of the medical officer, happily, must be complied with, however obnoxious they may be to a few landlords.

Dr. Robert Barnes, as President of the Metropolitan Branch of the British Medical Association, gave a *conversazione* on Wednesday evening at Willis's Rooms. A large number of guests were present, including Professor Abel, Captain Webb, Mr. Hyde Clarke, &c., as well as most of the members of the Metropolitan Branch, and many other distinguished men connected with the schools and the profession. The band of the Royal Marines played a selection of music during the evening; many works of art, scientific instruments, photographs, &c., were shown, and the hospitality of the host was evidently very much appreciated.

The tenth annual report of the sanitary condition of Merthyr Tydvil has just been issued by Mr. T. J. Dyke, medical officer of health for the district, and who is known as an energetic sanitary reformer. The present report, although well arranged, presents no special features of interest. We are rather surprised at the large number of deaths from scrofulous diseases recorded. No less than 92 children and 146 persons above five years of age were carried off last year by maladies bracketed under the heading of scrofula. Wet subsoil and damp foundations to houses doubtless account for this special mortality.

Dr. Septimus Gibbon, medical officer of health for the Holborn district, in a report lately issued, again reverts to the subject of congenital syphilis, the mortality from which is increasing in the parish, although Dr. Gibbon believes that the returns do not represent one-tenth part of the disease prevailing. There can be little doubt that the loss of health and of life in London due to syphilis is alarmingly great. Sooner or later the Contagious Diseases Acts, which are proving so beneficial in garrison towns, will have to be extended in other directions.

Mr. J. S. Baly, medical officer of health for Leamington, reports that comparatively little sickness existed in the town during the greater portion of the year 1874. In the third quarter of the year diarrhœa was rather prevalent, but, excepting this, very few cases of zymotic disease came under notice. As Leamington is one of our most popular health resorts, we are glad to receive such a satisfactory account of its sanitary condition as that given in Mr. Baly's report.

In London, last week, 1401 deaths were registered, including 11 from measles, 113 from scarlet fever, 12 from diphtheria, 44 from whooping-cough, 25 from different forms of fever, and 145 from diarrhœa. Different forms of violence caused 46 deaths.

The Social Science Congress was opened at Brighton last Thursday under the presidency of Lord Aberdare. On Monday next Dr. B. W. Richardson, the president of the Health section, will deliver an address to the members.

ON Monday last Sir James Paget presided at the distribution of prizes to the successful students of the Dental Hospital of London. The ceremony was held at Willis's Rooms. The spacious new premises of the institution, together with the excellent teaching staff, will not fail to attract an increasingly large number of pupils.

THE examinations for the certificate in State Medicine, instituted by the University of Cambridge, have been held this week. We believe about twenty-eight names are on the list of candidates. We hope soon to announce the result of the examinations.

ENTERIC FEVER is reported to be increasing in one quarter of Glasgow. Numerous cases continue to be reported, some of a very severe type, although the mortality is as yet small. It is estimated that about 20 per cent. in this particular part of the city have been attacked with typhoid.

THE guardians and other officials of Cannock have been called to account by Dr. Ballard, on behalf of the Local Government Board, by reason of the unsatisfactory state of vaccination in the district.

Correspondence.

"Audi alteram partem."

MEDICAL EXPERTS IN THE DAILY PRESS.

To the Editor of THE LANCET.

SIR,—I trust you will allow me to notice a letter inserted in your last number signed "F. R. C. P.," especially as reference is made to myself in what I consider to be an uncourteous and unjust way, and I am duly entitled to reply to it.

Allusion is first made to a letter of mine under the "sensational" heading "Homicidal Lunacy." This refers to a letter entitled "Criminal Lunacy in Scotland," which I sent to *The Times*, commenting on the "Cambuslang Murder." The editor, however, thinking the term "Homicidal Lunacy" more appropriate, substituted it for the one I had chosen.

The *Glasgow Herald*, containing a fully detailed report of the case, was forwarded to me by my friend Dr. Browne. He was aware that the *Psychological Journal* [thus in original!—ED. L.], then passing through the press, contained a few remarks upon "Murders by Madmen," and I, therefore, naturally thought that it was sent to me to comment upon in my journal. This I should have done had not the report arrived too late and when all matter was in the press. I considered the case, however, to be of such importance in a medico-legal aspect that I decided to send my comments and opinion to *The Times*.

I did not for a moment suppose that anyone could have inferred from the words used in my letter, "to express an opinion," that I intended the opinion for Dr. Browne, who is one of the greatest living authorities in lunacy. I am sure there is no statement in my letter from which such inference could be drawn, and there was nothing further from my thoughts at the time. The opinion was *pro bono publico*, but "F. R. C. P." has put his own construction on my letter in order to serve his purpose and raise a sneer.

Tierney had been tried, found guilty of murder, and sentenced to death, the jury recommending him to mercy in consequence of the *excitement* which might have existed from previous attacks of insanity. From the wording of the verdict the case appeared to me to be one in which doubt existed in the minds of the jury. Such being the case, I had a perfect right, especially as I considered the verdict an unjust one, to express an opinion on the case.

I must remind your correspondent that lunacy is a subject of interest not only to the profession, but to the world generally, and the columns of the press are open for discussion in disputed cases of insanity.

I cannot imagine how your correspondent can be under the mistaken impression that a physician is *not* entitled to express his opinion in a case of lunacy except he has actually seen the lunatic. An opinion formed upon careful and deliberate analysis of the full details of a case is surely entitled to some consideration, especially as it is the special province of psychologists [thus in original!—ED. L.] to frequently base their opinion upon written statements.

It is, however, a great satisfaction for me to know that the Home Secretary, in his subsequent investigation of the case, formed the same opinion as that expressed by

Your obedient servant,

Cavendish-square, Oct. 5th, 1875. L. S. FORBES WINSLOW.

SYMPATHETIC OPHTHALMIA.

To the Editor of THE LANCET.

SIR,—In "A Practical Treatise on Diseases of the Eye," recently published for me by Messrs. Macmillan, there occurs the following passage, which forms part of my observations on the channel through which sympathetic ophthalmia may be excited in a previously healthy eye by injury to its fellow:—

"Mr. Vose Solomon accuses the optic nerve, but only on the ground that, in a single instance, sympathetic ophthalmia followed enucleation of the eye in a patient of his own, whose optic nerve, on account of some imperfection in the scissors employed, was bruised at the place of division, instead of being cleanly cut."

In writing these words, I believed that I was correctly stating the substance of a case which Mr. Solomon had himself communicated to me some years ago, and also the substance of his own inferences from the facts related. Mr. Solomon, however, repudiates both the circumstance which I have mentioned, and the opinion which I have attributed to him; and I am unable to lay my hand upon the written history with which he furnished me.

On referring to an article, mainly on sympathetic ophthalmia, which I contributed to the *British and Foreign Medico-Chirurgical Review* for January, 1868, and in which Mr. Solomon admits that his own views are correctly stated, I find that the incident of the contused optic nerve and the subsequent sympathetic disease is described in a passage which I translated from the *Ophthalmiatrische Beobachtungen* of Dr. Mooren; and hence it seems probable that my recollection has played me false, and that I have fallen into an error in attaching the name of Mr. Solomon to a statement which is in all other particulars correct. I have arranged with Messrs. Macmillan to add to the present list of *errata* in my book that the name of Dr. Mooren should be read instead of that of Mr. Solomon in the passage referred to, and I shall be much obliged if you will give publicity to this explanation, and will at the same time allow me to express, both to Mr. Solomon and to yourself, my regret that the necessity for so troubling you should have arisen.

I am, Sir, your obedient servant,

Wimpole-street, October 4th, 1875. R. BRUDENELL CARTER.

LIVERPOOL.

(*From our own Correspondent.*)

THE opening proceedings of the winter session at the Liverpool School of Medicine were on this occasion rendered additionally interesting by the presence of Prof. Humphry, F.R.S., who, at the request of the Council, kindly undertook to preside and distribute the prizes gained during the two previous sessions. The proceedings commenced with the reading of a report by the registrar of the progress of the school during the past twelve months. An important feature in the report was the announcement that, by the will of the late Roger Lyon Jones, a sum of £2000 had been left for the purpose of founding scholarships. It was also suggested that these scholarships might be devoted towards encouraging and assisting students to work for the higher degrees, such as those of the University of London.

Dr. Dickinson's introductory address then followed. It mainly consisted of an interesting and erudite sketch of the state of medicine among the ancients, the lecturer concluding with some sound advice to the students.

Professor Humphry, before handing the prizes to their respective recipients, offered some eloquent remarks on the subject of knowledge, the power of applying it, and the value of competitive examinations.

In the evening the annual school dinner took place at the Adelphi Hotel, under the presidency of Mr. Reginald Harrison, which was numerously attended, Professor Humphry being amongst the guests. One most melancholy event cast a gloom over the proceedings of the day. I allude to the death, at Manchester, of Mr. Michael Harris, previously a distinguished pupil at Guy's Hospital, and more recently (for the last two years) the deservedly popular Demonstrator of Anatomy in the Liverpool School of Medicine. He was justly described by one of the speakers as "a type of what a healer of men should be—courteous, pure, unselfish, an honourable gentleman." His untimely end (a victim, I hear it said, to the want of a holiday) is most deeply deplored in Liverpool by a large circle of friends.

Liverpool, October 4th, 1875.

NEW STUDENTS.

THE following is a return up to Thursday of the number of fresh students at the metropolitan medical schools this session:—Guy's, 89; University College, 75; St. Thomas's, 67; St. George's, 44; King's, 30; St. Mary's, 30; London, 27; Charing-cross, 24.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Sept. 30th:—

Harvey, T. Prickard, Pryland-road, Newington-green-road.
Kellard, J. T. W. Stenteford, Trafalgar-place, Stoke Devonport.

The following gentlemen passed the Primary Professional Examination on the same day:—

Alex. Anderson, St. Bartholomew's Hospital; Samuel George Betty, John Hopkins, and Henry Frederick Harvey, University College; Francis Wheeler Brown and Fredk. W. Dobson McGachen, London Hospital.

MR. C. P. LUKIS has obtained the Open Scholarship of £100 for one year at St. Bartholomew's Hospital.

THE annual general meeting of the Spring Gardens (late Medical) Club, S.W., will be held at the Club on Wednesday, 13th October, 1875, at 4 o'clock P.M.

DR. NEWHAM, medical officer of the 3rd District Winslow Union, has been awarded the extra payment for efficient vaccination for the fourth time.

COMPLAINTS having been made to the Denbigh Corporation that the veterinary surgeons they employ to inspect cattle brought into town place their hands in the mouths of diseased animals, and then straightway inspect sound animals, thereby carrying the infection on their hands, a resolution was passed requesting them to discontinue the practice.

THE drainage of Maidstone, at a cost of £30,000, has been decided upon. The plans are those of Mr. Angell, C.E., who will lay down twenty-seven miles of pipes, and conduct the sewage out of the town to a point where it will be filtered and subjected to the clarification of lime process. The solid matter will be retained in tanks, and the effluent water, in its clarified state, discharged into the Medway.

UNIVERSITY OF CAMBRIDGE.—Professor Humphry has given notice that the course of lectures on Practical Anatomy will commence on Monday, Oct. 11th, at 9 A.M., and be continued daily till Oct. 19th, after which they will be continued on Mondays, Wednesdays, and Fridays. The course on Anatomy and Physiology will commence on Thursday, Oct. 21st, at 1 P.M., and be continued on Tuesdays, Thursdays, and Saturdays. This course is intended for students of Natural Science, as well as for medical students.

OVARIOTOMY IN ITALY.—The Italian journals are still reckoning the number of cases of ovariotomy performed in Italy. It has now reached sixty-three. The operation was performed by Paolo Rossi, head surgeon to the hospital of Vicenza, but, unfortunately, was unsuccessful, the patient dying twenty-six hours afterwards.

AT the Hull Police-court, William Shepherdson, late secretary of the Hull Infirmary, was charged on remand with embezzling several sums of money, the property of the institution. Mr. Hodgson, who appeared for the prosecution, stated that the accounts of the institution were still under examination, and he applied for a further adjournment. Dr. Rollit, who appeared for the defence, offered no objection, and the accused was further remanded, bail—two sureties in £200 each, and himself in £400—being again accepted.

DEATH FROM CHLOROFORM.—An inquest was held last week on the body of a man whose death was found by the jury to have resulted from the inhalation of chloroform. It appeared that the deceased was taken into St. Thomas's Hospital with a dislocated arm, which was put right under chloroform. By some means the bandage got disturbed, and the joint again displaced, and at the patient's request chloroform was again administered in order that the limb might be once more restored to its position. Whilst the operation was being performed, however, the patient died.

THE Native Guano Company are not to be allowed to carry out their sewage scheme at Kingston without encountering serious opposition. The proposal to erect two immense sewage tanks—with an open evaporating surface—on the banks of the Thames has alarmed the inhabitants of Hampton Wick, on the other side of the river, who believe that the works will not only be an annoyance but also detrimental to their health. The question was discussed at a meeting of the Hampton Wick Local Board on Monday, and after the proposal had been strongly condemned by the City Solicitor, the matter was referred to a committee.

LOUGHBOROUGH INFIRMARY AND DISPENSARY.—On Friday evening last a testimonial, consisting of a handsome timepiece and a valuable gold chain, was presented to Mr. Henry Bennett Bailey, on the occasion of his resigning the post of house-surgeon to this institution, which he has held for nearly five years. The presentation was made to Mr. Bailey at the house of Mr. Arthur Eddowes, one of the consulting surgeons to the institution, by Mr. E. W. C. Middleton, on behalf of the subscribers, who expressed the esteem in which Mr. Bailey was held by all classes in the town, and the regret felt at his departure.

SUSPECTED POISONING OF HORSES.—The "Melbourne Argus" of May 4th says that, several valuable horses having recently died from inflammation of the stomach and intestines, the owners requested Mr. Graham Mitchell, V.S., to investigate the matter. From the post-mortem appearances, he suspected that something injurious had been given to the animals in their food, which, on being examined, was found to contain a large proportion of *Lolium temulentum*. Samples having been submitted to Baron von Mueller and Mr. Cosmo Newbery, these gentlemen confirmed the opinion given. As this seed is frequently found mixed with wheat and barley, it would be of importance to have this matter thoroughly investigated.

DONATIONS &C. TO MEDICAL CHARITIES.—Mr. Thomas Jessop, Alderman and ex-Mayor of Sheffield, has undertaken to pay £22,000, the whole cost of erecting a new Hospital for Women in that town.—Mr. James Tyrer, of Bournemouth, bequeathed £10,000 to be divided between several charities, amongst which are—the Royal Hospital for Incurables; the Liverpool Infirmary; the Liverpool Dispensaries, the Liverpool Northern Hospital; the Liverpool Southern and Toxteth Hospital; the Liverpool Hospital for the reception of persons suffering from infectious and contagious diseases; the Stafford Infirmary; and the Bootle Infirmary. The Annual Report of the Newcastle Dispensary acknowledges the receipt of £10 000 (less duty) under the will of Mr. Wm. John Hutchinson, £1212 16*s.* 10*d.* under that of Mr. James Pigg, and £200 (less duty) under that of Mrs. A. G. Watson, and a donation of £1000 from Mrs. Mather. The Newcastle-upon-Tyne Infirmary has received £1000 under the will of Mr. Benjamin Tulloch.

Medical Appointments.

Aldersey, W. H., F.R.C S.E., has been appointed Medical Officer for the Havant District of the London, Brighton, and South Coast Railway Provident Society, vice Stedman, resigned.

Boase, F., M.R.C.S.E., has been reappointed Medical Officer of Health for the Penzance Urban Sanitary District.

Brown, W., M.R.C.S.E., L.R.C.P.L., has been appointed House-Surgeon to the Royal United Hospital, Bath, vice Greensill, whose appointment has expired.

Burroughs, G. F., M.R.C.S.E., has been appointed Medical Officer for the Battersea District of the London, Brighton, and South Coast Railway Provident Society, vice Sutcliffe, whose appointment has expired.

Carey, E. G., M.B., L.R.C.S.Ed., has been appointed Resident Medical Assistant at the Dundee Royal Infirmary, vice Brock, resigned.

Cassan, T., L.R.C.P.Ed., M.R.C.S.E., has been appointed House-Surgeon to the Royal South Hants Infirmary, Southampton, vice Clark, resigned.

Charles, J. J., M.D., has been appointed Professor of Anatomy and Physiology at Queen's College, Cork, vice Corbett, resigned.

Denniston, Mr. J., has been appointed Resident Medical Officer to the Greenock Hospital and Infirmary, vice Carlyle, resigned.

Evans, L. D., L.R.C.P.Ed., L.M., M.R.C.S.E., has been appointed joint Medical Officer to the Festiniog Slate Quarries, vice Thomas, deceased.

Fentem, P. S., M.D., M.R.C.S.E., has been appointed Medical Officer of Health for the Northern Division of the Bakewell Rural Sanitary District, and the Baslow and Bubnell Urban Sanitary Districts.

Foster, Mr. W., of Sidney Coll., Camb., has been appointed Lecturer on Chemistry at the Middlesex Hospital Medical College, vice Heisch, resigned.

Grant, J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the Parishes of Birsay and Harry, Orkney, vice Garson, resigned; and for the Parishes of Grœmsay and Hoy, vice M'Pherson, resigned.

Hammond, R. E., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer of Health for the Gorton Urban Sanitary District: £40 for one year.

Harris, J. A., M.D., M.R.C.S.E., has been appointed Medical Officer of Health for the Chorley Rural Sanitary District, vice Rigby, resigned: £150 per annum.

Harsant, W. H., M.R.C.S.E., has been appointed House-Surgeon to the Bristol General Hospital, vice Elliott, resigned.

Hayes, P. J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Resident Medical Officer and Apothecary to the Cork Union Workhouse, vice O'Kelly, appointed to the Limerick Union Workhouse.

Heale, A. L., M.R.C.S.E., has been appointed House-Surgeon and Secretary to the Royal Hants County Hospital, Winchester, vice Smith, resigned.

Hingston, A., M.R.C.S.E., has been reappointed Medical Officer of Health for the Liskeard Urban Sanitary District: £20 per annum.

Joseph, Dr. J. R., late Surgeon to the Belgian Royal Mail Company, has been appointed a Surgeon-Superintendent in the Queensland Government Service.

Knox, J., M.D., L.R.C.S.Ed., has been appointed Medical Officer of Health for the Southern Division of the Bakewell Rural Sanitary District, and the Bakewell, Matlock, North Darley, and South Darley Urban Sanitary Districts.

Maynard, J. C. M., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer to the Black-boy Colliery, Bishop-Auckland, vice Canney, deceased.

Newham, Dr., has been appointed Registrar of Births, Marriages, and Deaths for the Winslow District.

O'Keeffe, M., M.D., has been appointed Professor of Materia Medica at Queen's College, Cork.

Oswald, H. R., M.B., C.M., has been appointed House-Surgeon to the Scarborough Dispensary and Accident Hospital, vice Elliott, resigned.

Paterson, W., M.D., has been appointed Certifying Factory Surgeon for Chorley, vice Rigby, resigned, and Medical Officer for the Chorley No. 1 District of the Chorley Union, vice Tobin, resigned.

Phillips, J. D., L.F.P. & S. Glas., L.M., has been appointed second Assistant Medical Officer to the Fisherton House Lunatic Asylum, Salisbury, vice Andrews, resigned.

Pink, T., M.R.C.S.E., has been appointed Resident Surgeon to the Royal Sea-bathing Infirmary, Margate, vice Richmond, resigned.

Procter, T., M.R.C.S.E., has been appointed a Resident Medical Officer to the York Dispensary, vice Mawson, resigned.

Renny, A. W., M.B., C.M., has been appointed Resident Medical Officer to the Royal Stirling Infirmary, vice Purves, resigned.

Sarjant, J., M.D., L.R.C.P.Ed., M.R.C.S.E., L.M., has been appointed Medical Officer to the No. 2, or Ashburnham District of the Battle Union, Sussex, vice Simons, resigned.

Scobell, T. E., M.R.C.S.E., has been appointed Medical Officer of Health for the Ivybridge Urban Sanitary District.

Scotland, Dr. T., has been appointed Medical Officer for the No. 1 District of the Newcastle-on-Tyne Union, vice Nesham, resigned.

Thomas, W. H., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Llangonoyd District of the Neath Union, Glamorganshire, vice Davies, whose appointment has expired.

Thomson, E. W., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Medical Aid Society, Macclesfield, vice Macmillan, appointed House-Surgeon to the Macclesfield General Infirmary.

Tobin, G., M.R.C.S.E., has been appointed Medical Officer for the Chorley No. 2 District of the Chorley Union, and Public Vaccinator for the Chorley and Coppull Districts, vice Rigby, resigned.

Treutler, W. J., M.B., C.M., has been appointed Medical Officer and Public Vaccinator for the Maresfield District of the Uckfield Union, Sussex, vice Cresswell, resigned.

Walsh, S., M.B., has been appointed Medical Officer and Public Vaccinator for the Brewood District of the Penkridge Union, Staffordshire, vice Crean, deceased.

Wilson, Adam, L.R.C.P.Ed., L.F.P. & S. Glas., has been appointed Medical Officer to the Newcastle and Gateshead Provident Medical Society, vice Davidson, appointed Medical Officer to the Lead Company's Workmen's Medical Union, Alston.

Wilson, Alex. C., M.D., C.M., L.R.C.S.Ed., has been appointed Public Vaccinator for the Doncaster District of the Doncaster Union, vice Rigby, resigned.

Births, Marriages, and Deaths.

BIRTHS.

Bellingham.—On the 22nd ult., at Castle-street, Dudley, the wife of J. Bellingham, M.R.C.S.E., of a daughter.

Hood.—On the 29th ult., at Bridge-street, Tow Law, the wife of Geo. Hood, M.D., F.F.P. & S. Glas., of a son.

Paterson.—On the 29th ult., at Brigg, the wife of Walter H. Paterson, M.D., of a daughter.

Sheldon.—On the 3rd inst., at Cornwall-road, Notting-hill, the wife of T. Sheldon, M.D., of a son.

Wilcox.—On the 21st ult., at Holly House, North Walsham, the wife of Wm. Wilcox, L.R.C.P.Ed., of a son.

MARRIAGES.

Gould—Wilson.—On the 21st ult., at St. Matthew's, Brixton, Henry Gould, M.R.C.S.E., of Northfleet, to Emily Florence, daughter of Charles Wilson, Esq.

Martin—Ward.—On the 4th inst., at Holy Trinity Church, Twickenham, the Rev. Septimus Martin, M.A., of Fairlawn, Twickenham (fourth son of H. Martin, Esq., of Southtown, Great Yarmouth), to Persis, youngest daughter of the late Dr. Martindale Ward, of Markham-square, Chelsea, sister of Dr. Martindale C. Ward, of Saltburn, Twickenham.—No Cards.

DEATHS.

Atkins.—On the 22nd ult., at Ottery St. Mary, Devonshire, Wm. Atkins, L.R.C.P.Ed., aged 58.

Bunce.—On the 29th ult., at Norwood, John S. Bunce, Ext. L.R.C.P.L., aged 59.

Harris.—On the 28th ult., at Manchester, Michael Harris, M.B., Assistant-Physician to the Children's Hospital, Pendlebury, near Manchester (younger son of Michael Harris, Esq., of Penbury-road, Lower Clapton), aged 26.

Lardner.—On the 21st ult., at Gillingham, Kent, Jason Lardner, M.R.C.S.E., aged 70.

Murray.—On the 29th ult., at Waterloo-bank, Oldham, Chas. Murray, M.R.C.S.E., aged 40.

Part.—On the 1st inst., at Camden-road, James Part, M.D., aged 66.

Ross.—On the 26th ult., at Hart-street, Bloomsbury, Geo. Ross, M.D., aged 58.

Tailer.—On the 7th ult., at Walton, Suffolk, Geo. W. Tailer, M.R.C.S.E., aged 59.

Tucker.—On the 1st inst., at Sligo, James Tucker, M.D.

Walker.—On the 28th ult., Joseph Walker, M.R.C.S.E., of Burslem, aged 69.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

BOOKS ETC. RECEIVED.

Dr. Fox: Atlas of Skin Diseases.
Mr. Spencer Watson: Diseases of the Nose.
Drs. Beard and Rockwell: Medical and Surgical Uses of Electricity.

Notes, Short Comments, and Answers to Correspondents.

Professor Bouillaud.

This Nestor of the Faculty of Medicine of Paris has just resigned his Chair of Clinical Medicine. Dr. Bouillaud is nearly eighty years old, and up to a late period went round the wards of the Charité Hospital with almost the energy of youth. The professor is highly esteemed in Paris, and is known abroad as well as in France for his labours respecting diseases of the heart. He still, however, remains a most active member of the Academy of Medicine and of the Academy of Sciences. Only a few days ago M. Bouillaud was at the Medical Congress of Brussels, where he met with a most enthusiastic reception.

Mr. Broome Pinniger.—The case is a very sad one; but the patient seems to have been chiefly at fault in not sooner seeking relief.

Insurance against Sickness.

To the Editor of The Lancet.

Sir,—I was rather surprised at not seeing any answer to "L.S.A.'s" letter on the above subject in your last week's issue. I should think there are a great many country medical practitioners who would gladly join such a Society. I, for one, would do so, and I should be glad to assist in establishing it; but I am afraid my duties would not permit me to take any active part. Still I should be happy to do anything that lay in my power.

I am, Sir, yours very truly,
Great Missenden, Oct. 7th, 1875. Jas. O. M'Creery.

Zeal and Knowledge in Chelsea.

The sanitary authorities of Chelsea are displaying unequivocal proofs of their zeal. They contemplate prosecuting the Imperial Gas Company, under the Public Health Act, for the "nuisance" arising from their works, although technically, we believe, the premises are in Fulham. We shall watch the result with much interest, because it is clearly of importance that sufferers from any nuisance should possess the power of enforcing its removal, although the location of the cause of offence may be outside the arbitrary boundaries of the district in which the sufferer resides. Meanwhile, how are we to account for the circumstance that the medical officer of health in Chelsea recommends that licences for twenty-nine slaughter-houses in the parish should not be opposed? Ought the fact that only twenty-nine instead of thirty-five applications have been made on this occasion to outweigh the consideration that every slaughter-house in an urban district is a source of peril to health and a public nuisance? The drainings of a slaughter-house cannot, under the most favourable circumstances, be safely allowed to pass into the common sewers of a densely populated district, and the effluvium arising from most of these places is in itself a serious cause of annoyance and injury. The knowledge that slaughter-houses ought always to be outside populous neighbourhoods should serve to direct the zeal of the officials of Chelsea into a useful channel. While they prosecute the Gas Company, they might with consistency and advantage oppose the licensing of twenty-nine local nuisances.

"Cheap Doctors."

To the Editor of The Lancet.

Sir,—The subject of private dispensaries being now an established fact beyond the criticism of journalism—as much so as special hospitals are,—a few words upon the relative benefits to patients and attendant may not be unacceptable at the present time from one who has devoted himself to that class of practice during the past seven years.

In the first place, ready money payment encourages independent feeling upon both sides, satisfying the attendant upon the immediate occasion, entirely disposing of the heartburnings upon the presentation of medical accounts; avoiding the dunning system of collection and the ungraceful contention at the County Court; diverting money from the prescribing druggist's counter to the more legitimate pocket of the legally and practically qualified medical man. Again, the fee being small, many of honest principles, who would otherwise add to the already overcrowded out-patient department of the hospital or parochial dispensary, are able to obtain relief within their means.

The physician or surgeon of a private dispensary obtains an aptitude of prescribing and rapidity of diagnosis only acquired by large and constant practice. If he is only devoted to his work, he is quickly appreciated, and readily acquires a large *clientèle*. My own dispensary has only been started since May, and I now prescribe for a thousand cases every week. My name is attached to my work, even as most men attach theirs to the book advertisements in The Lancet or daily papers, for the information of those whom it may concern. I am at all times willing to defer to the opinion of The Lancet as a guide in most professional matters; but at present neither The Lancet, Medical Council, nor the Halls or Colleges protect the qualified practitioner from the invasions of the druggist or gratuitous prescriber. These will only disappear before the accumulation of private dispensaries, as will also the poverty of too many of our members.

Your obedient servant,

October, 1875. P. V. Timothy, L.R.C.P. Lond., &c.

To the Editor of The Lancet.

Sir,—As I live in a district where the majority of my patients are able to pay only the very lowest fees, I was highly interested by the very sensible and practical letter of your correspondent, "S.," in the last number of The Lancet. I shall be very grateful if he will inform me as to the method of starting and conducting such a dispensary as his own, and specially as to the scale of charges, method of collecting the money, rules for attendance of patients, and any other information he may deem useful.

Yours obediently,

October 4th, 1875. M.D.

⁂ The letter of "S." was certainly not complete. The information asked for by "M.D." will, doubtless, be supplied by our correspondent.—Ed. L.

B.—A. by no means resigned the management of the case or the duty of using the forceps by calling in B. It would be a very awkward thing if, whenever a medical man called in another in an obstetric difficulty, he gave up the chief conduct of the case. It would be quite another matter if A. had asked B. to apply the forceps.

Dr. Broadbent's second lecture "On the Pulse" will appear next week.

Locked Heads in Labour.

To the Editor of The Lancet.

Sir,—The occurrence of locked heads is, I think, sufficiently rare in obstetric practice to call for a notice of the following case.

On June 5th, 1875, I was asked to attend Mrs. A——, aged thirty-three years, pregnant for the fifth time. On arrival I found the body of a dead child outside the vulva, and the head of another tightly packed in the pelvis. I soon ascertained that I could only overcome the difficulty by decapitation of the first child, and delivery of the second, and the head of the first. Dr. Tyndale Watson, of Tottenham, gave me his assistance, who, upon examination, concurred in my opinion. We procured the bass wire of a pianoforte, which, being a wrapped wire, made a very good écraseur, and the head of the first child was quickly taken off, and pushed out of the way. The second head was seized with forceps by Dr. Watson, and the child was born barely living. We failed to resuscitate it after an hour's perseverance. I removed the remaining head with forceps, the placenta with two cords coming away soon afterwards. The mother made an excellent recovery.

Your obedient servant,

West-green, Tottenham, Oct. 5th, 1875. J. Bunting, M.R.C.S.L.

The Scientific Congress of Gratz.

This is the time of the year for meetings of this kind. Those of Nantes and Brussels have been very successful, the latter being exclusively medical; but the meeting in the Austrian city of Grätz was of greater magnitude, for it comprised science in general, brought together savants from the whole of Germany, to the number of nearly two thousand, and was divided into a great number of sections. The members, including the fair sex accompanying them, were enthusiastically welcomed by the highest authorities of the land and by the learned of Austria. Indeed among the ladies was a female professor, named Dodel, whose presence was highly valued by the whole assembly. At the first general meeting, Sept. 18th, eloquent discourses were delivered by the most prominent men, among whom should be mentioned the Arctic explorer Weyprecht. Medical science has, as usual, a large share in the labours of this, the forty-eighth, Congress. Another Congress took place on the 14th of September at Carlsbad, exclusively intended for the members of the profession practising in watering-places.

A. R. C. L.—It would be unwise to let the boys return to school at present. There would be great danger of the rest being attacked.

Band Subscriptions.

To the Editor of The Lancet.

Sir,—The question as to whether medical officers "employed temporarily" with a corps, and not shown in the official monthly Army List as "attached," are obliged to pay band subscriptions or not, has again cropped up in this country. I may say that in most regiments the question seems to have been settled very fairly, and in accordance with the Queen's Regulations—viz., that they are liable to a monthly subscription to the mess, but *not* to the band. However, a correspondent, signing himself "Case in Point," writes as follows in the *Pioneer* of the 8th inst.:—"With reference to 'Surgeon's' letter in your issue of the 4th inst., a surgeon in the Bengal Presidency has just paid band subscription to a regiment while temporarily attached to a detachment of that regiment over a hundred miles from the head-quarters and band of the regiment. This was done by order of the general, confirmed by H.E. the Commander-in-Chief, pending reference to the Horse Guards on the subject." The writer should have said "temporarily *employed*" instead of "*attached*." We must carefully distinguish between the two terms, as the Queen's Regulations define them very clearly. For example, in sec. 7, par. 39 *a*, we read: "If their names appear in the Army List as attached to regiments, they will pay," &c.; and 39 *b*: "If not so attached, but employed temporarily," &c. This paragraph refers to *mess* subscription, which comes to about 10*s*. a quarter, and which no one objects to pay. It is to sec. 7, par. 52, referring to the band, that I wish to draw attention. It says: "The following contributions and subscriptions to the band fund are to be paid by regimental officers," &c. Now, a "*temporarily employed*" surgeon can in no sense be called a *regimental* officer, and therefore cannot be called on to pay band subscriptions. The common sense view of the question ought to be sufficient to decide it. A temporarily employed surgeon uses the mess for his own convenience, and should pay something towards the expenses; but the band is kept up "for the good of the regiment," so to speak, in which he can have but a temporary interest.

Yours truly,

India, Sept. 9th, 1875. Surgeon.

A Prehistoric Wooden Leg.

L'Union Médicale states that in an island in the Mississippi a human skeleton has been found supplied with a wooden leg. The latter was fixed to the trunk by leather straps and some bronze-looking metal, which had turned fossil. Thus it would appear that oak as well as metal were used in prehistoric times.

An Appeal.

To the Editor of The Lancet.

Sir,—Will you kindly allow me a corner in your journal to make an appeal to the charitable among your readers on behalf of the widow and family of a medical brother?

The gentleman referred to, after practising some time in South America, settled in the neighbourhood of Edinburgh, where he resided to the time of his death. This event took place somewhat suddenly several months ago, and he has left a widow and family of six children (the eldest but nine years of age) in very straitened circumstances. The widow is a native of Chili, and has no relatives of her own in this country. As there is no prospect of her being able to support herself and her family here, she is naturally very anxious to return to her own country and friends. It is with the object of assisting her to do this that the present appeal is made. It is not considered prudent to mention names; but reference is kindly permitted to Drs. Warburton Begbie and Joseph Bell, of this city; or to the Rev. J. Langwill, The Manse, Currie, near Edinburgh, the latter of whom, or the subscriber, will be most happy to receive contributions in aid of this charitable object.

I am &c.,

J. Jamieson, L.R.C.S. Ed.

52, Rankeillor-street, Edinburgh, Oct. 4th, 1875.

Enquirer.—The procedure is very unsatisfactory; but it is within the bounds of law. There is no specification of the maximum time that must elapse between a practitioner seeing a patient and filling up a death certificate. Our correspondent should send us a short letter for publication, detailing the discreditable connexion.

Medicus in Rure.—It would be more magnanimous not to make such a claim.

Gas-stoves.

To the Editor of The Lancet.

Sir,—Will you or some correspondent inform me which is the best form of *gas*-stove for warming bedrooms—whether that in which the pipe passes through pumice-stone, or that in which a reflector is used? Which is the best mode of cleansing water-cisterns?

Yours truly,

London, Oct. 1st, 1875. M. B.

Extreme Arctic Cold.

A French contemporary lately reproduced a paper read this year by Payer before the Geographical Society of Vienna "On the Influence of Arctic Cold." A few extracts from it may prove interesting. The author started on March 14th, 1874, on a sledge to make fresh observations on hitherto untrodden ice-fields. The cold on that day was 40° (Réaumur) below zero. After a time the spirit ration became as thick as oil, and had lost its stimulating properties. It was impossible to smoke. Cigars and tobacco were turned into ice. Pieces of metal which the travellers had with them had the same effect when touched as red-hot iron. Great cerebral disturbance took place, accompanied with extreme thirst, difficult to assuage. Every noise was transmitted a great distance. The senses of taste and smell were almost in abeyance. Mercury could be made into balls. The secretions were augmented, whilst perspiration entirely ceased. Some of the difficulties to be encountered by the members of our Arctic expedition may be imagined from this brief notice of the recital of Payer's experience. It may perhaps be necessary to state that Lieutenant Payer is an explorer of the highest veracity and honour.

Mr. G. Brenan is thanked for his offer, which, however, we are compelled to decline.

Case of Triplets.

To the Editor of The Lancet.

Sir,—I send you the following account of a case of labour that I attended, thinking it might possibly interest some of your readers.

At about half-past nine on Sunday morning I was called to attend a woman in labour. It was her second confinement, her eldest child being fifteen months old. On making an examination I found the breech presenting, and in a few minutes she was delivered of a living female child. On now tightening the umbilical bandage I found that there was more to come. When the uterus had recovered its repulsive power, and when the membranes were sufficiently low, I ruptured; the right hand and arm then came down, and I turned and delivered my patient of a second female child. On readjusting the bandage I found there was yet another; but I had to wait an hour and a half before the uterus recovered its contractile power. After a few sharp pains, the membranes being then sufficiently low, I again ruptured, and, as in the first case, found the breech presenting. By passing my index-finger round the upper part of the thigh, I delivered the woman of her third living daughter. The average weight of each child is 4 lb., and mother and children are doing well.

The case presented the following peculiarities:—In neither case did the head present. All were females. There was very little liquor amnii on rupturing the membranes of the first two; but with the last perhaps a gallon or more. The mother is light-complexioned and very delicate. I was with her about three hours, and after the labour was over I had the greatest difficulty in keeping her from sinking from the shock and exhaustion.

I am, Sir, yours sincerely,
Great Smith-street, S.W., September, 1875. G. F.

Nocturnal Medical Assistance.

This question has been mooted at Paris, and it has been stated that at St. Petersburg each district is divided into subdivisions, which latter are supplied with a nocturnal medical watch, where patients are treated gratuitously. The papers publish every morning the names of the doctors and pharmaceutists on duty. In Chili not only the doctors are mentioned, but likewise midwives. Every medical man is bound to take up the watch in his turn. Matters are carried so far in Valparaiso that an eminent physician who had refused to take his turn was expelled from the place.

Maunsell Memorial Fund.

The following additional subscriptions have been received on behalf of the above:—

Subscriptions will be received by Dr. Joseph Rogers, 33, Dean-street, Soho, London.

Ratepayers and Paupers.

To the Editor of The Lancet.

Sir,—Allow me to ask your readers for an explanation on the following subject. How is it that the ratepayers are burdened with burying the bodies of unclaimed paupers, when the medical schools throughout the kingdom are anxiously willing to buy them? On this point I can testify as to the accuracy of my statement, having been a surgeon to a workhouse and to an asylum. I am, Sir, yours faithfully,

Hanmer Dickson,
September, 1875. Late Resident Surgeon, Asylum, Bristol.

Isolation Indispensable.

It is satisfactory to learn that the recent outbreak of fever at Islington is now under control, and that the malady has assumed a mild form. But it is the reverse of reassuring to find that, notwithstanding all that has been proved and admitted with regard to the necessity of isolating cases of infectious or contagious disease, the parochial school buildings did not allow the authorities of Islington to take this obvious precaution. Nothing can excuse the neglect to provide adequate means of perfect isolation in all districts. It is a mere question of money, and the parsimony which refuses to discharge a public duty is deservedly punished by ultimate loss. The Local Government Board should do more than "inquire" into these cases. Unfortunately the Board is not armed with full powers of coercion. The national dread of "centralisation" produces grotesque consequences, and the feebleness of the Local Government Board is most conspicuous. Local authorities are meanwhile not one whit the less responsible to public opinion because they cannot be compelled to do their duty.

An Eleven Years' Subscriber.—A foreign degree cannot now be registered. We are not in a position to advise our correspondent on the subject.

The Influence of the Use of Wind Instruments on Chest Affections.

To the Editor of The Lancet.

Sir,—Being myself a cornet player, I read in your issue of Aug. 14th the remarks of Dr. Burq on the above subject with very great interest.

During the past five years I have taken charge of the bands of three regiments I have served with, and have, of course, had the sole treatment of the men when they have fallen sick. I cannot remember a single severe case of chest affection in a musician (in the cold season the sepoys are often attacked with pneumonia, which disease is more fatal to natives than it is to Europeans). The musicians in native bands are frequently undersized, both as regards height and chest capacity. It is a common thing for men who have been rejected for the ranks to learn some instrument, which they do very quickly, and then get enlisted for the band. There is one point I have noticed with both Europeans and natives, and that is, men who play wind instruments are generally to the front in athletic sports, particularly in running.

I began blowing with strong lungs, and feel they are now stronger; but do not consider myself able even to offer an opinion as to the effect likely to be produced on unhealthy lungs. If, as Dr. Burq contends, the blowing of wind instruments produces a healthy state of lung, then we have a mode of treatment which must prove very agreeable to most patients. I think there can be no doubt that heart disease is far from uncommon amongst those who play on wind instruments, and the most trying of all is the oboe.

I remain, Sir, your obedient servant,
India, September, 1875. Musician.

Dr. Bacon.—It is the same individual. It would be difficult to find two persons capable of such irrational nonsense.

M.D., L.R.C.P.—The practitioner is the best judge of such a question, especially in the case of old patients.

Treatment of Lymphatic Tumours.

To the Editor of The Lancet.

Sir,—I have just read with great interest in your journal of Sept. 4th Mr. Bradley's paper "On a New Mode of Treating certain Tumours of the Lymphatic Glands," and if the method will do what he promises, and is not attended by risks which can only be ascertained by enlarged experience, it will be a very valuable addition to our means of treating these obstinate affections. I am not quite sure, though, whether he is correct in calling it a *new* method, unless the using a new substance by an old way be a new method, in which case there might *possibly* be as many new methods as substances capable of being injected; or unless his experiments were made and conclusions arrived at before 1873; for if anyone will turn to page 457, vol. ii., of The Lancet for 1873, he will find an abstract of a paper by Dr. Luton, in which the same treatment of lymphatic tumours by injection is advocated, substituting iodic acid for iodine. Since reading this article on Luton's method, I have practised it in three cases, and with perfectly satisfactory results, my only doubt being as to whether the tumours might not have subsided spontaneously, though more slowly, if they had been left alone.

Mr. Bradley's paper, though, is a great deal more than merely the introduction of a new method; it is an epitome of the surgical treatment of almost all glandular enlargements of the neck connected with the lymphatic system, and, as regards private practice any way, some will doubt the propriety of the third rule. Yours obediently,
Blackpool, Sept. 28th, 1875. Wm. Hardman.

Mr. Led.—We must be excused from giving our correspondent any advice about cheap hair-dyes.

Mr. Bryant's address has been received, and will be published at an early date.

Mr. Jeremy Bentham's Remains.

To the Editor of The Lancet.

Sir,—Allow me to inform "A Correspondent" that the skeleton of Mr. Jeremy Bentham, dressed in a suit of his clothes, may be seen sitting in a glass-case in the anatomical museum of University College, London. Although the case is in a retired place away from public gaze, I believe there is no difficulty in obtaining permission to view the remains of the great jurist. It will be remembered that Mr. Bentham, who died in June, 1832, bequeathed his body to his physician and friend, Dr. Southwood Smith, for the purpose of dissection. Shortly after death Dr. Smith gave a lecture on the body in the School of Anatomy, Webb-street, Maze-pond. After this the skeleton was preserved, and eventually came into the possession of Sir John Bowring, who presented it to University College.

Your obedient servant,
October 4th, 1875. J. T.

The Grape Cure.

Wiesbaden, the well-known and lovely watering-place, has of late been, according to the views of gamblers, shorn of its greatest attractions. The roulette is gone; but some people have thought that a good opportunity had offered to organise in the autumn along the handsome colonnade every desirable comfort for the grape cure. When it is recollected that this mode of treatment has mostly to be carried out in dull and outlying villages, at a time of the year when fogs and damp are very common, it will be conceded that a gay city is far preferable. It is confidently stated that this novelty will be a great success in Wiesbaden.

J. W. B.—The powerful remedies mentioned should be taken only on the advice of a medical man.

Mr. Alfred T. Wilson.—An excellent work.

A Serious Matter.

To the Editor of The Lancet.

Sir,—In my letter published in The Lancet of July 24th, I offered to give the name of the gentleman who was attempting to pass the L.R.C.P. examination at Edinburgh by proxy to any of the examining boards of the United Kingdom who applied to me for it. I considered that some, at least, of the boards would have taken this precaution against being deceived by this man; but not so, for I have not been asked for his name by any one of them. I think this fact is worthy of note, but requires no comment to point out its significance. Your obedient servant,

A. Pearce Gould, B.S.

Gower-street, Bedford-square, October, 1875.

⁂ It seems the clear duty of the examining bodies to take up this matter. We are surprised that no attention has been paid to Mr. Gould's letter.—Ed. L.

M.D., (Manchester.)—MM. Deneffe and Van Wetter, of Belgium, have, we believe, testified to the harmlessness and efficacy of the intra-venous injection of chloral hydrate.

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from — Prof. Corfield, London; Prof. Humphry; Mr. Erichsen, London; Mr. Gordon Brown, London; Dr. Broadbent, London; Mr. Harrison, Liverpool; Dr. White; Mr. Pigou, London; Mr. Timothy, Barrow-in-Furness; Dr. Gill, London; Miss Solomon, London; Mr. Casson, Hull; Mr. English, Port Elizabeth; Dr. Speedy, Dublin; Mr. Budham; Mr. F. Smith, Weston-super-Mare; Mr. Brenan, Hastings; Mr. Robertson, London; Mr. Watson Dove, Wells; Mr. Miller, Launceston, Tasmania; Mr. Beck, Cambridge; Mr. Hermon, Leek; Dr. Renny, Stirling; Dr. Haviland, Northampton; Mr. King, Ware; Mr. Beatie, London; Dr. Rogers, London; Mr. O'Shaughnessy, Kilmalock; Mr. M'Creery, Great Missenden; Dr. Crowe, Leamington; Dr. Grindles, Normanton; Mr. Payne, London; Dr. Hulme, Wigston; Mr. Hatton, London; Dr. Broom, Sheffield; Mr. Gibson, Loughborough; Dr. Redwood, Rhymney; Mr. Harris, Hackney; Dr. Dickinson, Liverpool; Dr. J. A Clinical Lecture

ON

THE PULSE: ITS DIAGNOSTIC, PROGNOSTIC, AND THERAPEUTIC INDICATIONS.

Being Lecture V. delivered at St. Mary's Hospital in the Summer Session of 1875,

By W. H. BROADBENT, M.D., F.R.C.P.,
PHYSICIAN TO THE HOSPITAL.

Gentlemen,—I told you in my last lecture that there were three factors in the production of the pulse—namely, the heart, the small arteries by means of the muscular coats, and the large arteries by their elasticity. We considered chiefly the heart, on which, as I pointed out, depend the frequency, force, and rhythm of the pulse. I may here add that the indications afforded by the action of the heart are of importance chiefly in *acute* disease. But the action of the heart, and therefore the rate, rhythm, and force of the pulse is greatly influenced by the small arteries; on them, however, more especially depends the character of the pulse, which may be said to be determined by the peripheral resistance. I mentioned only one element in this peripheral resistance—the contraction or relaxation of the muscular walls of the minute arteries; but there is another element which must not be lost sight of, though the part which it plays is not definitely known—the degree of facility with which the blood traverses the capillary network.

On considering the results of relaxation and contraction of the arterioles on the pulse, we found that the following variations in character must necessarily accompany these opposite conditions. When we feel the pulse, if the arteries are relaxed the diameter of the vessel is increased and the pulse feels *large, quick* or *short,* and *soft,* the tension being low. With contracted arteries the converse obtains in each particular. The diameter is diminished and the pulse feels *small;* the blood passes through the vessels with greater difficulty and more slowly, and the pulse becomes *long;* the tension is high and gives it the character of *hardness.*

With regard to the effect produced on the pulse by the aorta and large arteries, I stated in my last lecture that they equalised the flow of the blood; they have, however, besides this, other and highly important effects, which are best shown by the sphygmograph, and to which I will now briefly call your attention.

The sphygmograph is invaluable as an exact means of observation, and has been a great means of educating us how to feel and properly appreciate the pulse—has, in fact, as I said, rediscovered for us the indications furnished by the pulse. It will never come into use in general practice, for it demands not only time and care at each application, but also a careful preliminary training. It is an instrument of precision and requires a skilled workman. The value of its revelations depends entirely on the intelligence which is brought to bear on its employment, and if carelessly used it can only lead to error. A good rifle is more sure to hit if the aim be good, but it is more sure to miss if the aim be bad. Completely different tracings may be obtained from the same pulse by variations in the pressure employed. The employment of the exact pressure which will best bring out the features of the pulse is a matter of skill, and, the amount of pressure required being an important item of knowledge, great uncertainty arises here. Moreover, not only is it in the operator that sources of error may arise; the instrument itself, by variations in its construction, may invalidate the result for all purposes of comparison. To interpret a tracing satisfactorily certain details respecting the sphygmograph producing it must be known, and much experience is required to render the tracings by different instruments comparable. Not only may there be inaccuracy in the determination of the force of the spring, but the size of the pad applied to the artery will make a difference in the amount of pressure required. The smaller the pad, the weaker must be the spring; and if a knife-edge be applied in place of a pad the results will be more delicate, and the pressure required to obtain a perfect tracing, or to compress the artery completely, will be still less.

I have some tracings here* (kindly furnished me by my friend and colleague, Dr. Mahomed, of whose skill and experience I am glad to avail myself), which I now pass round for your inspection; they afford examples of the normal form of pulse, of pulses of relaxed arteries with low tension, and of contracted arteries with high tension. In the normal pulse the first thing you notice is the line of ascent; this is sometimes sloping a little backwards, it terminates in a sharp apex, and then commences the line of descent. This portion of the pulse-trace has been called the *percussion* element. Sometimes, as in high tension, the line of descent is arrested immediately after its commencement, and the lever is kept up for a short period, or even again rises slightly. This shows that the artery remains full, the stream continuing. This is called the *tidal* wave. Lastly, you see, during the subsidence of the tidal wave, another elevation of the lever, which is especially well marked in pulses of low tension; this is caused by the *dicrotic* wave, and is due to the elastic recoil of the aorta.

The percussion element is somewhat exaggerated in these traces, from the fact that Dr. Mahomed has no spring over the writing lever; but it indicates the suddenness of the contraction, and as a means of recording this it is very valuable. The trace does not, however, exactly represent the movements of the artery, for when the percussion element is excessive, the writing lever is tossed up by the suddenness of the arterial expansion, and actually leaves the short intermediate lever which rests upon and follows exactly the movements of the spring which presses upon the pulse. The pulse has been described as consisting of three waves—the percussion, tidal, and dicrotic waves. The percussion and tidal are not, however, two waves, but two elements of the same wave. The distinction between these elements must be preserved, as each gives a character to the pulse; but the term "wave" is not applicable to the percussion element. This compound wave is entirely produced by the cardiac contraction, and is the chief wave of the pulse; it is that which in an ordinary way produces pulsation in the arteries, and it is only this portion of the pulse that we can usually feel. The cardiac systole produces pressure in all parts of the arterial system; this is not necessarily an onward movement of the blood, for if an artery be tied or compressed there is no onward movement at the point of obstruction, but there is still pulsation. There is, of course, onward motion of the blood in the artery when we feel the pulse; what we feel, however, and what the sphygmograph records, is not movement, but *increased pressure.*

But the entire force of the systole does not take effect in onward movement of the blood; part of it is expended in distending the aorta; and when systole ends the elastic walls of this vessel contract, and by their recoil produce another wave or increase of pressure in the artery—namely, that called the dicrotic pulse wave.

Dicrotism is a phenomenon of arterial relaxation and low tension. Under these circumstances the blood is passing freely and rapidly through the arteries; the heart, meeting with little resistance, contracts rapidly and suddenly; the aorta, like a spring in a position of rest, is exerting very little pressure on its contents, and yields readily to the sudden distending force, and the rebound, which itself meets with less resistance, is consequently greater. At the wrist what occurs is as follows: the artery, being relaxed, is completely flattened by the spring of the sphygmograph; then by the contraction of the heart it is suddenly filled, and as it is large and relaxed the movement is great, the lever is tossed up suddenly and then falls; in its fall it receives a slight momentary check by the distension caused by the tidal wave not passing off so suddenly as the percussion effect; and then comes the rebound of the aorta, producing the dicrotic wave at the wrist.

Dicrotism sufficiently marked to be of any importance can almost always be appreciated by the touch. For this purpose the three fingers must rest on the vessel in the lightest possible manner, and, attention being given, the dicrotic beat is felt like an echo of the principal wave. Dicrotism can be thus distinguished in most cases of severe pyrexia, in the early stage of typhus, through a great part of enteric fever, and very frequently after fatigue, bodily or mental.

---

* It is not necessary to reproduce them, as the characters of the sphygmographic tracing are well known.

Hyperdicrotism is said to be present when the dicrotic wave appears in the upstroke of the trace: the dicrotic wave is overtaken, so to speak, by the percussion of the next pulsation, the fall of the lever being intercepted before it has reached its lowest point. It is simply a phenomenon of excessive frequency of pulse, with relaxation of arterioles. When with extreme frequency there is extreme weakness of the heart's action, the trace becomes *monocrotous* and the pulse fluttering—a condition of fatal prognostic significance. Conversely, if the tension be high, the systole is prolonged because of the resistance in the aorta; the aorta, already tense, cannot yield much, it cannot, therefore, rebound. At the wrist the artery is small, and is not easily flattened. The percussion wave is consequently not so high; the tidal wave, on the other hand, is more sustained, and there is little or no dicrotism on account of the constant distension of the aorta.

Another effect of the elasticity of the aorta is the delay in the transmission of the primary wave of pressure to the wrist. If a system of rigid tubes be taken to represent the arteries, with fenestræ covered by membrane introduced into the system of tubing, one near the heart, the other near the termination of the tubing, and two sphygmographic levers be placed over these membrane-covered openings, the two levers will be seen to rise simultaneously at each contraction; whereas, if the same observation be made with elastic tubing, a considerable interval will elapse between the movements of the two levers: the greater the distance they are apart, the longer will be the interval between their respective movements. This experiment explains the cause of the delay in the pulse at the wrist, which, as you know, is not perfectly synchronous with that in the carotids.

The effect of loss of elasticity in the aorta is seen in the senile pulse, which is characterised by a long tidal wave and a diminution in dicrotism; but, although the pulse is long, it is not hard, but is readily compressed. This character distinguishes it from the pulse of high tension.

Relaxation of the arterioles is induced physiologically by external warmth, exercise, fatigue, &c.; pathologically, by pyrexia &c.; experimentally, by various agents—nitrite of amyl, alcohol, Calabar bean, &c.;—contraction, by cold, renal disease, gout, lead-poisoning, digitalis, &c. But this is not the place for the discussion of such causes. I must, however, give the characters of the pulse resulting from a combination of different modes of action of the heart and different conditions of the minute arteries, enumerating the principal states of system in which each form of pulse is met with. I exclude here heart disease, as the pulse of the different valvular and other diseases of the heart will form a separate study on some future occasion.

The action of the heart being frequent and powerful, and the minute arteries being relaxed, the pulse will of course be *frequent* and *strong*, but *large, soft, short,* and *dicrotous.* When well marked this is the full and bounding pulse of medical writers, but the degree varies greatly. The pulse will have these characters during and just after exercise, especially when there is perspiration; in most pyrexias; in the early stage of most fevers and of acute rheumatism; in pneumonia.

If the heart is weak, but beating rapidly, while the arteries are relaxed, the pulse will be *frequent, weak, soft* and *short, dicrotous,* or perhaps *hyperdicrotous,* or, in an extreme case, *fluttering* and scarcely perceptible. You will observe that I do not say large, for a certain amount of *vis a tergo* is required for this. The pulse described is found in states of debility, more especially when febrile; in the later stages of fevers, in the typhoid state so-called; it is the usual pulse of the moribund.

When with frequent and forcible action of the heart the arteries are contracted, we have the *frequent, small, incompressible, long* pulse. It is met with during rigors, in the early period of acute gout, in acute renal dropsy, in many cases of scarlatina (constituting a difference between scarlet fever and most other fevers), in peritonitis and enteritis, in pleurisy also, and in meningitis.

When the heart's action is weak and the arteries contracted, the pulse becomes exceedingly small, and is often spoken of as "wiry" or "thready," or the former epithet is employed when with a very small artery there is some strength. This pulse is present in its most pronounced form in general peritonitis with collapse, but I have found it in the last stage of phthisis, and in pulmonary gangrene.

It is not my intention, however, to discuss the state of the pulse in acute disease; I wish rather to dwell in greater detail on the state of the arteries in the absence of acute disease; for the study of these conditions has afforded me some of the most valuable knowledge acquired in the course of years of observation and experience; more especially is this true of the recognition of the condition of tension and the causes of its variation.

(To be concluded.)

An Address
ON
MEDICAL STUDY AND EXAMINATIONS.

Delivered at the Liverpool School of Medicine,

BY PROFESSOR HUMPHRY, F.R.S.

[THE Medical School at Liverpool has undergone considerable alteration and enlargement. A new anatomical and pathological museum has been built, physiological and chemical laboratories have been added, and the dissecting-room has been much enlarged.

At the opening of the session on Oct. 2nd the chair was taken by Professor Humphry, of Cambridge. There was a large attendance of medical men and other residents in the town, as well as of medical students. The introductory address was delivered by Dr. Dickinson, who gave a summary of the history of medicine. Before distributing the medals and prizes Professor Humphry, having complimented Dr. Dickinson on the able and interesting manner in which he had made the leading figures of olden times to pass before them, and shown the part which each had taken in forwarding the great science of medicine, and had presented their examples to those who were to enter upon the same career, spoke as follows.]

It is now our pleasant duty to turn from the good and great of the past to the good and hopeful of the present, and to confer the tokens of honour and reward upon those who were most successful in the good fight of last session's work. I say upon those who were most successful, for let it be borne in mind that it was a contest in which all were more or less successful; none were losers; all were winners, forasmuch as all came out of that contest better men than they went into it. True, it was not possible for each one to boast that he was able

Æἰὲν ἀριστεὺειν καὶ ὕπειροκον ἐμμεναι ἀλλων—

("To aim at highest honours, and surpass
His comrades all");—

but it had been possible for each one to do what was far better and more important than to surpass his comrades all—viz., to surpass himself. It was especially a contest in which

"'Tis better to have fought and lost
Than never to have fought at all."

Indeed, it was in some respects better to have fought and lost, provided the student had fought well, than to have fought and won; for he who had fought and lost had, at any rate, the advantage of being able to measure his own strength more advantageously than he who had won could do; and he would also have learned a lesson of humility, inasmuch as he would have found that there were others better than himself, and he would derive the stimulus of finding that further effort was necessary to win in the race of life. I would therefore seriously advise all who are commencing the session's work to determine to enter these lists, not for the purpose of beating others so much as for the higher and better purpose of beating themselves—not with the idea of winning the prizes commonly so called, but with the intention of winning the much more important prize of self-improvement. Everyone who tills his mental ground well, who digs deep and sows good seed, though he may fail to reach the treasure which he possibly has more immediately in view, will be certain to gather the more valuable treasure of a good and productive harvest, and will go away with joy bearing his sheaves with him. If it be a truth, as it undoubtedly is, and one of those great truths which are too little appreciated, that virtue is its own reward, so is it no less a truth that good honest work, work of all kinds, and especially good mental work, is its own reward; indeed, the best and highest reward that accrues to it is that which is inseparable from it, which grows of necessity out of it, and which results partly from the satisfaction of increased knowledge gained and of the consciousness of increased power and opportunity for usefulness. For there can be no question that the love of knowledge is one of the distinguishing features of man, one which is graven deeply in his character, and which is common to all mankind. No savage, no human being, however low and degraded, is altogether without it. Nay, it would seem from the biblical record to have been regarded as constituting a weak element in man's nature, and as presenting a side in his character upon which the tempter might most surely and fatally assail him; and this is represented, not as a feature in the character of man only, but as being perhaps even more marked in woman. Nor are we to understand that this refers to that low kind of love of knowledge called inquisitiveness or curiosity; but that it was the desire for an acquaintance with the higher things that concern our destiny, for the knowledge of good and evil, which furnished the opportunity to loosen man's resolves and to shatter his obedience. However that may be, of this I am certain, from much observation of men and manners, that nothing contributes more assuredly to steady, quiet happiness in life than a love of knowledge and the means, which may almost always be found, of gratifying it. This inherent love of knowledge we should take as a cardinal fact in considering how best to conduct education. We should take it for granted that in every one of our pupils this important and hopeful feature exists; and the great problem in education is, how to carry on efficient teaching without weakening this feature—how to give instruction sufficient to meet the growing needs of civilisation without damping and extinguishing this spark which is so essential to give warmth and life to the whole. I believe it is to be done in one way, and one way only: and that is, by associating ideas with the facts taught; by taking care not simply to communicate facts, but to communicate with them their relations, purposes, and surroundings, their being's use and end; for these constitute the life and power of facts, these give them their interest, and give to those who acquire them the power to use them. Without these adjuncts the learned in facts is like a builder encompassed by masses of material but unable to employ them because he is ignorant of their properties and relations. True the builder cannot work without the materials; neither can he construct without a knowledge of the materials, however abundant they may be. The most successful teachers have ever been those who enlisted the interest of their pupils by giving life to their subjects: in other words, who enlivened the details of their descriptions by the association of ideas and views; who not only taught facts, but taught with them what really constitutes the knowledge of the facts, and this knowledge gave pleasure and satisfaction and power to the hearers. It is this kind of knowledge which is power; and rarely will students be found careless and inattentive to it. When the teacher observes that his pupils are dull, reluctant listeners, he will do well to consider whether the fault does not, in part at least, lie in his method of teaching, in the absence of that kind of information which gives interest to the subject and forces the student to take interest in it; and when the student drags heavily along his path, and fails to find objects of interest to excite his attention and exercise his thoughts, he may depend upon it that the deficiency is in the direction or alertness of his mental vision. There are flowers and fruit enough along the way if he can but take the trouble to perceive and gather them. One of the great difficulties in carrying out this kind of teaching and learning is undoubtedly to be attributed, at the present time, to the examinations. Here let me not be misunderstood. I do not undervalue examinations. I have already advised you to go in for the competitive examinations in your school; and I believe that examinations form an important, indeed an essential, element in education. They, together with the preparation for them, tend to clear the mental atmosphere, and give precision, strength, and availability to knowledge in a way that can be effected by no other means. At the same time, like most other good things, they are liable to be mingled with some alloy; and that alloy is the evil known to be engendered under the system which is implied by the expressive and comprehensive little word "cram." Now cram is the filling or stuffing the mind with facts undigested—a *rudis indigestaque moles*,—without their being shaped and sorted and appropriated, and accompanied with that kind of knowledge which, as I have just said, constitutes the life and power of the facts and gives them their interest. Hence the study becomes dreary, dull, and repulsive. How inexpressibly lamentable is it that such a study as that of medicine should, by any possibility, have terms of this sort applied to it;—a study in which the best and most interesting features of physical science are concentrated upon the elucidation of the highest and most interesting of physical objects, and that not only in its ordinary and natural state, but in its abnormal and morbid conditions. There can be no question that the highest of all the physical studies is the study of the aberrant or abnormal conditions of the human body considered in relation to physiology on the one hand, and to pathology and treatment on the other; unless it be that which may, indeed, be regarded as a division of the same subject, and which, in a growing civilisation, is the most important division—that, namely, which relates to the prevention of disease. That such a study should become dull and repulsive is scarcely conceivable, and would seem to require a prodigious amount of bad teaching and bad study and bad examining to make it so. Yet, alas! we know that this is too much the case—that too many men learn no more of it than they are compelled to do, and learn that little heartlessly, grudgingly, and unwillingly. That this is so is, to my mind, the serious and discouraging feature which now confronts us in medical education, and indeed in all education. How to prevent or diminish it is the great educational problem of the age; and for the solution of this problem we must look first of all to the improvement of the examinations. Examinations are a rapidly increasing force in this country. They are becoming the masters of education. The students will learn, and the teachers must teach, with reference to them. Such, therefore, as are the examinations, such will, of necessity, be the teachers, and such will be the students. The improvement in the style and character of education must begin with the examinations; and the great improvement required in them is that to which I have already alluded—namely, the making them tests, not simply of facts acquired, but also of the knowledge of the facts and of the power to wield them. We want, not simply a knowledge of practical facts, but (which is a very different thing) a practical knowledge of facts. I am well aware of the great difficulty of conducting examinations so as to effect this, and to give a stimulus in the right direction to teaching and study. Herein is shown the ability of the examiner as well as the thorough knowledge of his subject. What I say on this matter is the result of much experience in examinations, passive, active, and neuter. In the passive sense I underwent an unusual amount of examination in my early medical career, and, though I recognised their good influence, I used heartily to long for the time when I should be absolved from their tyranny and be at liberty to range freely in the pleasant pastures of medical study. Actively, I have had my share in conducting examinations, and I live in a place where education and examinations enter largely into our thoughts and duty, where, in short, they form the staple article of business; and I have always been impressed with the great difficulty of conducting examinations well, and have been by no means satisfied with my own efforts to carry out my desires. As a neuter, I have, in the capacity of a member of the General Medical Council, had the opportunity of visiting and reporting on medical examinations in each of the three divisions of the empire; and though I am glad to testify that the examinations which I had the honour to visit were on the whole well conducted, still I was impressed with the difficulty of so conducting them as to exercise a high influence on education, and to give the required stimulus to teachers and students—the stimulus to enable and induce them to teach and study in that higher manner which constitutes real education, and which carries both interest and power with it. I think the tendency, in anatomy especially, is to lay rather too much stress upon minutiæ of detail, and to regard too little the teleological bearings. This, perhaps, is partly to be attributed to the dissociation of physiological from anatomical teaching, which has, I think, tended to exert an evil and depressing influence on the latter. I have always been thankful that when I commenced the study of anatomy the influence of John and Charles Bell had not altogether paled before that of their more exact but less enlivening successors. Whatever view may be entertained on such a point as this, I feel that it is now more than ever necessary to watch examiners and examinations narrowly, and to enlist the highest ability and wisdom in fashioning this, which is the very corner-stone of the educational edifice. The importance of this subject must be my excuse for dilating upon it; but time presses, and I will return to the more immediate business of the day. Some of you are about to enter into practice or are practitioners already. It is a trite piece of advice to you that you should remain students still; but I can give you no better. Foster carefully the flame of the love of knowledge in yourselves by feeding it with good fuel. It will contribute to your happiness more than almost any other thing. It will tide you over the many vexations and trials and disappointments incidental to professional life, and carry you above them in a level of quiet composure. The varied studies of medical men—such as botany, chemistry, physiology, &c.—give them the advantage over other men that they are more likely to have acquired a taste for some branch of science or reading which they can fall back upon as a resource in times of leisure; and I always remark that those are the happiest in whom this is the case. Though it is true that the disturbances and uncertainties appertaining to professional life are great distractions from the pursuit of any settled course of reading, yet these very uncertainties, attended with frequent intervals of unoccupied time, render it peculiarly important that there should be some favourite study to resort to which may prevent the desultoriness of habit and thought which the irregularities of our daily life have a special tendency to promote. Of all our studies, pathology is the one which I would particularly recommend as advantageous from a professional point of view, both on account of the interest which attaches to it and the vantage-ground which it affords. Nothing can give greater assurance and solidarity in the diagnosis and treatment of disease than a good knowledge of the characters of the disease. Work at it microscopically. Read the standard treatises on it. Work carefully over the good and well-selected specimens in the pathological museum in this school before you leave it. Do the same with any other museum that may lie in your path. Do not despise the information to be obtained from specimens because they are in bottles. There is a vast deal to be learned from them. An hour or two daily may be more profitably spent in examining these specimens in bottles and reading the histories associated with them than perhaps in any other way. This is a source of knowledge second only to the examination of the bodies of those whose cases you have watched during life. In no direction is so large an amount of knowledge allowed to run to waste as in pathology, whether we regard the neglect of post-mortem examinations or the neglect of opportunities afforded by pathological collections. They are the weapons which death offers us to turn against himself, and we too much fail to take advantage of them. I am not, however, so anxious to suggest the particular line of study as to urge upon you to make some subject—some branch of literature, philosophy, or natural or medical science—your resource in the hours of leisure from active and engrossing professional occupation.

To you who are entering upon the session's work in the school I can do no better than endorse what you have heard from Dr. Dickinson. Your work is to be your pleasure, and will be so if you are going the right way to work. Let not the pass-examinations be too much in your thoughts. They are meant to be a terror to evil-doers, and not to the good; and in the preparation for competitive examinations, if your first object is to improve yourselves, they can be no trouble to you, and you cannot meet with disappointment. You have great advantages here. Your school is equipped with the appliances and means of practical study in the most approved manner as few other schools can boast, and remember that the credit and success of the school depend upon your good use of them.

After all, it is signally true of knowledge as of all other treasures, that the life of a man consisteth, not in the abundance of the things which he possesses, but in the motive which guides him in the use of them—the polar star around which his thoughts and actions revolve. What that polar star should be there is no need for me to tell you. Your own consciences will prove infallible pointers to it.

CASE OF MENINGOCELE ASSOCIATED WITH CERVICAL SPINA BIFIDA, CURED BY ASPIRATION.

By JAMES F. WEST, F.R.C.S.,
SENIOR SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

The occurrence of meningocele is not common, but less frequently do we meet with cases of this kind where there was not only a bony deficiency behind the foramen magnum, with protrusion of the membranes of the brain, but also, concomitantly, absence of the lateral arches and spinous processes of nearly the whole of the cervical vertebræ. Aspiration of the tumour on two occasions had the effect of causing its diminution to a great extent, and ultimately led to a closing of the aperture of connexion between the inside of the skull and the cavity in the interior of the meningocele.

The child lived eighteen months after the two operations, its death being caused by chronic hydrocephalus. Whether the hydrocephalus, which certainly did not appear to exist at birth, was caused or aggravated by the closure of the communication between the skull and the meningocele, it is of course impossible to say. At any rate hydrocephalic fluid began to accumulate in the ventricles very rapidly after the second tapping; it was probably in consequence of there being no outlet for the secretion at the back of the skull, as there formerly had been, that one so soon began to notice the great increase in the size of the head, due to the expansion and separation of the cranial bones, and the bulging of the membranes through the fontanelles. The *modus operandi* of the cure of the meningocele was, as I believe, a deposit of fibrous material, the result of inflammation at the neck of the sac, which occluded the opening into the skull. This was proved by the fact that at the post-mortem examination, after I had absolutely cut away the tumour altogether, none of the cerebro-spinal fluid escaped from the aperture. Further than this, the sac of the meningocele, from which I had once during life drawn off four ounces of fluid, was found at the time of the child's death to be so contracted that it would barely contain a couple of peas.

Very possibly the hydrocephalus, from which the child died at the age of twenty months, had its commencement prior to the operation, but that it was intensified by the paracentesis is more than probable. If, as Morgagni has observed in spina bifida attended with hydrocephalus, the enlargement of the head has been known to undergo a considerable diminution after the casual rupture of the tumour of the spine,* one can readily understand how an opposite condition, such as the removal of the sac of a meningocele or spina bifida, may tend to the increase of the hydrocephalic secretion within the skull, and to the consequent enlargement of the head.

Aspiration was, I believe, a perfectly justifiable proceeding, inasmuch as it was clear that there was neither cerebral nor cerebro-spinal material within the sac of the meningocele. Had there been reason for suspecting the presence of either a portion of the brain or spinal cord in the meningocele, I should not have thought of any operative procedure.

It is very likely that I might with safety have removed the tumour *en masse* with the écraseur after the second tapping, but as the child was evidently gradually sinking from chronic hydrocephalus, I could see no advantage in resorting to any further operation.

On May 17th, 1872, Mrs. X——, a delicate fair lady, aged twenty-five, was delivered of a female child after a natural labour. The mother, who had been weakly from her birth, was of a highly nervous temperament, and had a peculiar habit of rolling up her eyes while speaking, so that only the conjunctivæ could be seen. She had been confined once previously (Feb., 1870) of a healthy child, and in May, 1871, had suffered from a serious miscarriage at the fourth month, the placenta being retained and the consequent hæmorrhage having weakened her greatly.

---

* De Sed. et Caus. Morb., epist. 7, art. 9.

Family history.—She has three sisters, who are all delicate, and two brothers, who are said to be hale strong men. Her father looks well, but her mother is a fair, delicate-looking woman, and has had much illness. Her husband is a man of high mental but weak physical organisation, who has a winter cough and occasional hæmoptysis; his only brother has also suffered from phthisical symptoms.

The child, whose history I now proceed to narrate, was rather small; its neck was much shorter than natural, and the occiput seemed close to the shoulders. Behind the foramen magnum in the middle line was an opening into which the point of the forefinger could easily be introduced, and pendant from the back of the neck, and evidently proceeding from the opening in the skull, was a tumour, the size of a small orange; the swelling was fluctuating, translucent, and appeared to contain clear fluid only, and no solid contents; it became larger and more turgid when the child cried, but was small, soft, and flaccid when the child was asleep, and at no time was there any impulse when the hand was applied over it. The child's legs and arms were very diminutive; the thumbs were turned inwards over the palms, and the feet inverted so that they would probably in time have become varoid; the fontanelles were open to their usual extent, but no hydrocephalus was obvious at the date of birth. I diagnosed the case as a meningocele complicated with cervical spina bifida, and that opinion was shared by my friend and colleague, Mr. Furneaux Jordan, who saw the patient with me on June 21st, 1872. As there was no brain-substance, constituting encephalocele, within the sac, an operation to evacuate the contents of the tumour was considered justifiable; and, it having been consented to by the parents, to whom the risk was fully explained, I punctured with a small aspirating trocar on June 26th, and drew off two ounces of clear, straw-coloured fluid, which I judged to be cerebro-spinal. When the fluid contents were evacuated, one could clearly make out that not only was there a large opening into the skull, but that also all, or nearly all, of the laminæ and spinous processes of the cervical vertebræ were wanting. Collodion and a pad of lint were applied at the point of aspiration.

No bad symptoms followed the operation, but the tumour filled up again very soon, though its contents seemed less fluid and translucent.

On July 5th I again aspirated the tumour, and evacuated four ounces of yellowish, opalescent fluid. Great febrile excitement followed this second operation, and for two days the child was in considerable danger. The fluid contents did not again accumulate, and gradually the tumour diminished in bulk and increased in firmness, until it felt somewhat like a small fatty tumour, which retained the same size and appearance when the child cried and under all other circumstances.

Soon after the child was born the head began to enlarge, and the fontanelles to be very open.

Aug. 7th, 1872.—Mr. Wm. Adams, of the Great Northern Hospital, saw the patient with me, and the question of removing the tumour with the knife or écraseur was discussed, but as the hydrocephalus was on the increase, and the child's condition was very feeble, we decided that it was not likely to be of any permanent benefit to the child, and therefore that we could not recommend the operation to the parents.

Iron, cod-liver oil, and wheat phosphates were in turn used, with occasional alteratives of grey powder and rhubarb. Locally, spirit lotions and then gentle pressure were employed, but in spite of all treatment the head gradually enlarged, as will be seen by the following table, which shows the measurement of the circumference, and also the antero-posterior measurement of the head, from the root of the nose to the top of the cervical tumour.

1872.	Circumference.	Antero-posterior measurement.
Sept. 20th	17⅝ in.	13 in.
„ 29th	18⅛ in.	13 in.
Oct. 5th	18½ in.	13¼ in.
Oct. 10th	18¾ in.	13½ in.
„ 19th	19 in.	13½ in.
„ 22nd	19⅛ in.	13⅝ in.
„ 26th	19⅜ in.	14 in.
Nov. 6th	19¼ in.	14 in.
„ 27th	19¾ in.	14 in.
1873.		
Feb. 9th	21⅛ in.	16 in.
March 1st	21 in.	15½ in.
„ 6th	21 in.	16 in.
„ 28th	22 in.	16¾ in.
April 29th	21⅝ in.	16½ in.
May 13th	22⅜ in.	16 in.

During the succeeding six months the head increased but little; the frontal suture united, but the anterior fontanelle bulged widely. The child never had convulsions, but gradually got weaker, and passed away quietly on January 22nd, 1874.

I made a post-mortem examination, with the assistance of my dresser, Mr. Whitby, on the following day. The body was dreadfully emaciated: length 26½ inches; circumference of thorax, 14 inches. The hands were firmly clenched, with the thumbs directed across the palms. Circumference of head, 22¾ inches; antero-posterior measurement from meningocele to superciliary ridge, 17½ inches. The fold of the neck was quite lost at the back, and there was a tumour, about the size of a pigeon's egg or a small walnut, springing from just below the occipital protuberance in the middle line. There were circular patches of ulceration extending down to the cranial bones, in the right frontal, left parietal, and occipital regions, which had evidently been caused by pressure on those points. The tumour was first excised; no fluid escaped when the child was laid on its back, except a little blood from the aperture in the occipital region of the skull. The scalp being removed, the sagittal suture was found ossified, but the coronal and lambdoidal sutures were entirely membranous. On the membranes being punctured, only a few drops of blood oozed out; but on the lateral ventricles being opened, about two quarts of a pale clear serum escaped. The skull-cap, which was so thin that it could in most places be cut with a scalpel, being removed, the longitudinal sinus was found to be of a very large size and full of black blood. The internal surface of the base of the skull measured 6 in. by 5⅝ in. The lateral ventricles were so expanded that the cerebral substance enclosing them was only from a quarter to half an inch in thickness. The cerebrum itself was pale, soft, and diffluent; the cerebellum was moderately healthy, but there was a little fluid beneath the pia mater on the left side.

Condition of parts through which the meningocele escaped.—An opening, measuring 2 in. in length by 1 in. in width, extended from the foramen magnum backwards almost to the occipital protuberance. The posterior arches and spinous processes of the six upper cervical vertebræ were entirely wanting, and the spinous process of the seventh was deficient. The dura mater extended from the interior of the skull into the opening; but no portion of the cerebrum, cerebellum, or medulla spinalis was contained in the sac of the meningocele. The meningocele itself was as large as a walnut, was covered with fine, thin, light-coloured hair, and on section was found to consist of thickened skin and cellular and fatty tissue, with a small cavity in the interior, large enough to hold one or two peas. There was no communication between this small cavity and the interior of the brain, for none of the hydrocephalic secretion flowed out when the tumour was cut off and the child placed on its back, so as to allow the fluid if possible to gravitate towards the aperture at the base of the tumour.

Birmingham.

PHARMACEUTICAL SOCIETY OF IRELAND. — At a meeting of the Council of this Society, held on the 6th inst., four examiners were appointed to examine in the following subjects:—Latin, English, and Arithmetic: Dr. E. W. Collins. Materia Medica and Botany: Dr. W. G. Smith. Pharmaceutical and General Chemistry: Mr. H. Draper. Practical Pharmacy: Mr. R. Montgomery. Two of the examiners, Drs. Smith and Collins are, we understand, sons of members of the Council, the former being the son of the Vice-president of the Council, Dr. Aquilla Smith.

NOTES OF A CASE OF TINEA TONSURANS.

By J. THEOPHILUS BECK, B.A., M.R.C.S. Eng. &c.,
SURGEON TO THE WESLEYAN HIGH SCHOOL, CAMBRIDGE.

One of the pupils of the above school was submitted to me for examination and report as to the contagiousness or non-contagiousness of an affection of the scalp from which he was suffering. The boy had been sent to school with an assurance from the medical attendant of his family that no fear of contagion existed; and he supported this opinion by the fact that he had seen three cases of the same kind that had progressed to *entire* loss of hair, the hair, however, after a time growing again, and that other members of the respective families of these patients had not contracted the disease. A request was received from the parents of the lad that, if the patches of baldness extended, so as to become unsightly, he might be furnished with a wig, and his hair shaved off.

On examination, I found the patient a weakly lad, anæmic, and with defective appetite. There was a history furnished with him of three or four attacks of rheumatic fever, and on examining him I found a systolic mitral bruit. The rheumatism was attributed to defective asssimilation.

In consequence probably of his repeated illnesses, he was somewhat behind the other boys of his age in intellectual acquirements. He was exceedingly anxious to learn, and was a well-disposed lad, and all these circumstances rendered it desirable, if possible, to keep him at school.

I found on examination that the hair of the head generally was black, somewhat coarse and profuse in quantity, extending low on neck and forehead, fine dark hairs reaching to the eyebrows. There were ten or twelve bald patches, varying in size from a shilling to that of a halfcrown piece. The partings extending from one patch to the other were wider than natural. Some of these patches were white, but most of them appeared to have a thin brownish-yellow film, and had growing on them a few thin pale hairs, in marked contrast to the general quality of the hair. No complaint of itching or uneasiness. Some of the hairs extracted from the bald patches and their immediate neighbourhood, and submitted to microscopical examination by Dr. Wilson, demonstrator of anatomy, and myself, were found to be infested with the mycelium and spores of the Tricophyton tonsurans.

I considered that I had a case of tinea tonsurans, and gave the following opinion: that, although the fear of contagion was not so great as in other forms of tinea, yet that unrestrained intercourse with the other pupils was not free from risk. I therefore recommended a separate bedroom and entire isolation during the first week or two of treatment.

I was anxious, if possible, to save my patient from the annoyance and discomfort of losing his hair and wearing a wig—a matter of no small moment to a boy exposed to the witticisms and practical jokes of his schoolfellows. I therefore attempted, in the first place, to establish a line of demarcation between the healthy and unhealthy parts by extracting the hairs on, and a quarter of an inch around, the bald batches, and the same width on each side of the partings. This was a most tedious undertaking, and tasked alike the patience of the surgeon and the endurance of the patient. To give the boy credit, he bore it manfully and uncomplainingly, cheered by the hope of retaining his natural wig. After a few days the whole of the diseased patches were completely isolated. At the same time the hair was washed with a lotion of sulphurous acid and glycerine, and oil of cade and glycerine was applied to and around the patches by means of a stiff toothbrush. Glycerine was ordered in these lotions, with a view to prevent the dissemination of the spores of the fungus through the atmosphere. I then ordered the tincture of iodine to be applied night and morning for a fortnight, after which an ointment of bichloride of mercury was used. No fresh patches appeared after the commencement of the treatment, and by the end of the term I considered my patient cured, and contented myself with recommending a stimulating wash of ammonia and cantharides to be used during vacation to hasten growth of new hair.

On his return to school I had the satisfaction of finding that the cure was permanent, and that, instead of my patient having been reduced to a state of complete baldness, there was a growth of strong black healthy hair on the lately diseased patches.

I may add that my patient took syrup of iodide of iron and cod-liver oil while he was under treatment.

Cambridge.

CASE OF ANEURISM OF THE ARCH OF THE AORTA SIMULATING INTRA-THORACIC TUMOUR.

By FREDERICK ROBINSON, M.D., F.R.C.P.,
SCOTS FUSILIER GUARDS.

I thus venture to designate a case which, while illustrating the difficulty which besets an accurate diagnosis between aneurism of the arch of the aorta and morbid growths or deposits in the anterior mediastinum, presents some exceptional features of interest and instruction in a clinical point of view.

William F——, aged forty-one, an unmarried soldier of sixteen years' service, all passed on home duty, was admitted into the Regimental Hospital on the 24th May. He was known to be a man of intemperate habits, much addicted to drink. From the circumstance of his being a tailor by trade, and as such employed in the workshop with short intermissions during the whole of his military career, he had escaped that close observation as to health and habits which men on duty in the ranks are subjected to by medical officers and the military executive.

The occupation of the patient and mode of life are points to be borne in mind, inasmuch as the usual marked compression of the heart and arterial trunks (as well as of the lungs[*]), arising from the very defective make of soldiers' tunics, had in this case, it may reasonably be inferred, nothing to do with the origin of the malady. More probably habitual intemperance, as Dr. Peacock observed in this class of disease, by causing degeneration of arterial tissue, may have engendered the complaint. Possibly also syphilis contributed to this result, as the patient was under treatment in the year 1866, for a period of thirty-nine days, with the primary disease followed by secondary symptoms. Mercury and iodide of potassium were the remedies employed. This was the only admission into hospital of any consequence during the man's lengthened period of service, and there is no ground for believing that the constitution was left impaired by a disease which originally was not of a severe form,[†] and proved readily amenable to treatment.

The following were the symptoms on the morning of the 24th May:—Uneasiness referred to the top of the sternum; a fixed pain within the chest in this locality, not of severe character, nor extending down either arm or pectoral region in paroxysms; and dysphagia, so far as to make the passage of solid food uncomfortable but not impracticable. He prefers therefore liquid nutriment, which he swallows without any difficulty or limit as to quantity. Ordinarily there is little perceptible dyspnœa when quiescent, but if the patient move about or cough—as he does almost invariably when called upon to answer a question—the breathing is somewhat raucous. This condition subsides again, and he is able to respire easily and without distending the nostrils. There has been orthopnœa for a month past, obliging him to have his head raised a good deal in bed, and preventing rest on either side. The cough is not troublesome when he is perfectly still, but the least movement brings it on. It is rather loud in character, may be termed "tracheal," but is certainly not "brassy" nor high-pitched. No aphonia. The attacks of cough are usually followed by expectoration of thick mucus, like that seen in the after-stage of bronchitis. Has never had hæmoptysis. The man's aspect does not indicate much suffering, and is not suggestive of malignant disease. He is of sanguineo-lymphatic temperament, of healthy countenance, free from puffiness, and when he coughs the face becomes red without actual lividity. No difference in the pupils. The veins of the neck are distended on the left side. The right temporal artery cannot be distinctly felt. Firm pressure on the trachea causes slight pain. Nothing abnormal in the appearance of the chest, which is well formed, and, in common with the rest of the body, tolerably muscular.

---

[*] The evil consequences of tight collars and waists in causing heart affections or kindred disease have been sufficiently well known and commented upon by army surgeons. I am not aware that their influence in generating phthisis has elicited the like notice and condemnation, possibly because the results are less immediate and obvious. To myself, on grounds that with the present generally received views as to the origin of tubercle it is superfluous to enter into, such obstacle in the due performance of the function of the lungs has appeared to play a very important part in the causation of a disease lamentably frequent in the Foot Guards.

[†] Whether the syphilis was a hard chancre the records of the case do not show. The contrary is inferred, and also that some slight skin affection resulted.

On percussion, there is clearly-defined, "board-like" dulness over the upper half of the sternum, taking in an area which may be covered by the palm of a man's hand. This space extends more to the right side, and there includes fully an inch of the sternal ends of the first three ribs. No impulse felt, nor sound of any kind audible. Heart's sounds clear and regular, but feeble. Respiration in the right lung anteriorly indistinct; in the left lung throughout somewhat weak. Posteriorly on the right side there is dulness on percussion, from the inferior angle of the scapula downwards. Loud bronchial breathing in the supra-spinous space. Lower down the respiratory murmur is weak, with some loose crepitation. No pain is felt in the upper part of the spine, nor soreness on pressure there. The pulse is the same at both wrists, feeble, regular, 80.* The extremities are cold, and the surface of the body covered with damp perspiration. There are no enlarged glands in the axillæ or elsewhere.

The patient distinctly says that his complaint came on gradually, was not preceded by any strain or injury, and that its duration has not been longer than a month. As regards the latter point, his statement must be taken with some reservation, as he might wish to avoid censure for concealment of illness during a lengthened period. No gastric disturbance.

The symptoms pointed manifestly either to aneurism of the arch of the aorta or some morbid growth springing from or independent of the lung; and, after weighing all the symptoms, it appeared to me that the preponderance of evidence was in favour of the latter class of affection, notwithstanding its comparative infrequency. Hence it was diagnosed.

The patient was ordered a stimulating draught of ammonia and ether every second hour, together with strong liquid nutriment, and a moderate quantity of wine. As he complained of want of sleep for the last few nights, he was ordered in the evening, his pulse having improved, a sedative draught of tincture of henbane and camphor mixture. He passed a better night, and would have slept well were it not that the cough awoke him several times. His breathing was tranquil and not at all noisy on the morning of the 25th; but, as usual when he answered questions, coughing came on. A pellet of thick mucus was brought up at the end of each seizure. The coldness and dampness of the skin remained the same, and the pulse was as weak as on the morning of admission. He passed a very restless, sleepless night on the 25th. His intellect was disordered, he talked incoherently, and endeavoured to get out of bed several times. This excited condition came on during the after-part of the day and in the evening. The visiting medical officer, bearing in view the patient's past mode of life, considered such symptoms rather indicative of commencing delirium tremens. An opiate took no effect at the time; but on the morning of the 26th he was composed and rational—in fact, his condition was the same as at the like hour on the previous day. In the afternoon he was again restless; cough not more frequent than ordinary; faculties clear. About 10 P.M. he turned faint, asked for a glass of water, and, before he was able to drink any, fell forward and expired. He was sitting up in bed at the time.

Autopsy, fourteen hours after death.—Body muscular, well proportioned and nourished; no abnormal appearances of any kind. Intercostal and pectoral muscles red and firm. A thick layer of fat covered the sternum. On raising this bone it was found at the upper part to be closely adherent to a structure which resembled to the eye and touch a tumour, occupying the anterior mediastinum. It was yellowish-white in colour, oval and flattened in form, and imparted to the fingers the feeling of a somewhat lobulated fatty tumour. It was a little overlapped by the lungs, and the part visible was about the size of a closed fist turned upwards. There were about fourteen ounces of dark-red serum in the right cavity of the chest, and the inferior margin of the lung, adjacent to the pericardium, was blood-stained on the surface. The lower half of the lung (right) rather compressed against the spine.

On laying open the supposed tumour, about a teaspoonful of bloody serum escaped, and it was then apparent that the structure was an aneurism undergoing spontaneous cure, and far advanced in such process of reparation. It was of the class designated "false," the wall being formed of an agglomerated mass of enlarged bronchial glands, dense cellular tissue, and fat. The sac was in some places three-quarters of an inch thick. Filling it completely lay a large ball of decolourised laminated fibrine, firm as a piece of muscle. This weighed nearly thirteen ounces. The whole aneurism, when removed, was about the size of a small cocoa-nut, flat on the surface beneath the sternum, and convex elsewhere. Further dissection showed that it sprang from the arch of the aorta at its centre. The aperture was a slit through which a sixpenny piece could easily pass, and its margin was smooth and rounded. The surface of the aorta throughout was studded with patches of atheroma in an early stage, there being no calcareous deposit anywhere. Just above and behind the aortic valves a true aneurismal dilatation also existed—a pouch capable of holding a filbert. The pericardium was in a state of extreme tension, and on making a small puncture, a jet of dark bloody serum was ejected. The entire quantity could not be ascertained, but it was considerable. The heart then exposed was rather larger than normal, loaded with fat at its base, the surface pale, and greatly corrugated. The organ presented altogether a blanched, sodden appearance, such as might arise from its lengthened suspension in fluid. The inner structure of the viscus was firm, red, and tolerably healthy, as were the valves.

On careful examination, a small ulcerated opening, capable of admitting a probe, was found in the depending portion of the large aneurismal sac, near its junction with the aorta. This opening communicated with the pericardium, about an inch below the root of the aorta. The right lung floated when placed in water. It was rather congested at its base, and, when cut into, the bronchi showed evidences of chronic inflammatory action. The apex was puckered, shrunken, and solidified. On laying it open, cretaceous masses and fibrous bands showed that tubercular disease had existed, and that nature had effected a perfect cure. The other lung was quite healthy. Masses of fat, and glands much hypertrophied, surrounded the roots of these organs. The epiglottis was enlarged and thickened. The liver was a good deal enlarged and fatty. Both kidneys were increased in bulk, congested, and presented indications of incipient Bright's disease.

Observations.—In this case, perhaps, it may be conceded that the diagnosis, although, strictly speaking, inaccurate, was in some measure borne out by the physical and general symptoms, as well as by the condition of the contents of the thorax seen *in situ;* but that, rather from the comparative infrequency of thoracic growths weighed against aneurismal than any distinctive signs pointing to the latter affection, a more correct inference might have been drawn as to the true nature of the disease. The period during which the man remained under observation was short—but three days; and he was very reticent as to the past.

A point of interest lies in the immediate cause of death. We find Nature interrupted in her process of reparation when very far advanced; a small chink of communication with the pericardium opened out, and a gradual draining of serum established. My own conclusion is that this oozing commenced immediately before the patient's admission, and that the consequent exhaustion and alarm led him to seek relief at the hospital. Life would appear to have been extinguished by a mechanical process—the cessation of function by pressure of fluid and consequent paralysis of the heart.

A question now presents itself as to the origin of effusion into the right cavity of the chest. The state of the corresponding lung and absence of pleuritic deposits negatived any conclusion that the fluid depended on either source, while it differed from that ordinarily met with after lesion of those structures. It corresponded, however, exactly in character with the contents of the pericardium, and my opinion is that a condition of exosmosis obtained, and that the over-distended pericardium for a time thus relieved itself into the cavity of the chest. The portion of lung in contiguity with the heart was stained with blood on the surface, and over it probably the liquid flowed. A careful examination failed to detect any other aperture through the aneurismal sac by which its contents could have passed.

---

* A sphygmograph was not at hand, and the opportunity of obtaining a tracing of the pulse was lost.

This case illustrates well the fact, noticed by Dr. Sibson in his very instructive tabulated records of Aneurism of the Thoracic Aorta, that such disease of the vessel at the centre of the arch causes less suffering to the patient than affections of the ascending and descending portions of the artery. The difficulty in diagnosis, too, must be proportionately enhanced. The system, it would seem, can accommodate itself there to the presence of a growth of large size, and with comparatively small discomfort to the patient, provided the body be well nourished. I assume that this condition helped to lessen the man's distress, the aneurism being protected by fat on all sides from pressure.

I have looked over the Transactions of the Pathological Society, and cannot find a case similar in all its bearings, clinical and pathological, to the present. In none were the characteristic symptoms of aneurism of the thoracic aorta so obscure or absent altogether.

Claverton-terrace, St. George's-road, S.W.

NITRITE OF AMYL IN NERVOUS CEPHALALGIA.

By R. A. DOUGLAS-LITHGOW, L.R.C.P., &c.

Some six years ago I had my attention first directed to nitrite of amyl, and as this therapeutic agent is at present receiving great attention from the profession, I wish to make known one of its effects which I have found almost specific; and I do so more especially as I am not aware that the action of nitrite of amyl in nervous headache has been recorded recently. As will be seen, I lay no claim to the discovery myself. I think it was in 1869, whilst reading a number of the *Edinburgh Medical Journal*, I observed a remark made by the late Sir J. Y. Simpson, in the report of one of the meetings of the Edinburgh Obstetrical Society. He said he had found the inhalation of two drops of the nitrite give immediate relief in cases of nervous cephalalgia, however severe. From that time to this I have been in the habit of so using it, and, where due care was taken in the selection of cases, I have never known it fail to produce entire and almost immediate relief. In several instances I have had to increase or repeat the dose, but, as a general rule, two drops have been sufficient.

I place two drops on the palm of the patient's hand, and quickly diffusing these with my finger over the palmar surface, I tell her to cover her mouth and nose with her hand, and to inspire deeply and quietly. No time should be lost after the nitrite is dropped on the hand, as it evaporates rapidly. The patient should be seated while inhaling, as the peculiar effects of the nitrite are produced almost instantaneously, and may occasionally alarm a very nervous or hysterical female. Fortunately these symptoms last a very short time—generally less than two or three minutes,—and with their cessation the pain almost invariably ceases. Two drops may be given as a draught in water, instead of by inhalation, but I have found the latter mode much more satisfactory.

Dr. B. W. Richardson, to whom the profession owes almost everything concerning the true physiological action of this peculiar agent, says it is one of the most powerful relaxants of vascular tension we possess, and, bearing this in view, we can easily account for many of its physiological effects. I do not, however, propose to discuss these here, but I may just mention that, in addition to the "flushing of the face" which invariably results after the administration of nitrite of amyl, patients generally complain of great throbbing in the temples, "fluttering of the heart," and a feeling of breathlessness, as if they were "dying away." Some describe a sensation of "tingling from head to foot," and several have experienced pains in the limbs analogous to cramp, while in other cases every object seems to have acquired a bright yellow hue, such as sometimes results from the use of santonine. These severer symptoms, however, are by no means common.

Used as I have just recommended, I don't think there is the slightest risk in its administration; but, owing to the temporary palpitation of the heart produced in most patients, care should be taken in administering it in cases of organic cardiac disease, &c. Should any excitement or other alarming symptom occur, cold affusion to the head, face, and chest, with a free supply of fresh air, are the proper means to use, but I have never had occasion to do so. The nitrite (which is cheap) should be procured from reliable makers only, and, as an economic suggestion, I recommend anyone using it to preserve it in a stoppered glass bottle, having an additional glass cap-cover.

North Brink, Wisbeach.

REMOVAL OF A BULLET FROM THE HEAD SEVEN MONTHS AFTER ITS RECEPTION.

By ROSSLEWIN MORGAN, M.D.,
STAFF-SURGEON, ARMY MEDICAL DEPARTMENT.

I was consulted on the 12th of June, 1875, by a Chinese coolie, named Cheng Aboy, aged twenty-five years, who had a bullet firmly imbedded in the frontal bone, about three-quarters of an inch below the hair and midway between the coronal suture and a straight line drawn across the superciliary ridges and nasal notch, and about a quarter of an inch to half an inch to the left of the mesial line. The bullet was received during the Shanghae riots, in a fight between the Chinese and Malays, in December, 1874, seven months before he sought medical aid. It took an oblique direction, and was evidently a ricochet. When extracted it was triangular in shape, the base directed downwards and to the right side, the apex upwards and to the left. Its length was three-quarters of an inch, breadth half an inch, depth about half an inch, weight one ounce and three-fifths. Its external surface which was in contact with the integument was rough and rounded, its inner surface which was in contact with either the brain or its membranes, or possibly with a false membrane, was flat, rough, and coated with the clay which was used as a plug for it; its apex and inferior margin were imbedded beneath the os frontis; its base was partially free; it was covered over by the skin except a small spot in the centre, from which a thin unhealthy discharge issued.

I first tried to move it by a silver probe, but without effect; I then dissected up a circular portion of the skin, which I slit through with scissors in three directions, and being thus enabled to reach its base with an ordinary artery forceps (a bullet forceps being inapplicable), with a long-continued steady pull succeeded in extracting it. During the operation he became faint, but was revived by a little weak brandy-and-water.

The wound was dressed with a pledget of lint soaked in carbolic oil (one part to forty), which was retained *in situ* by a bandage; had a dose of castor oil, and a cold lotion constantly applied to the head.—5 P.M.: Has rather feverish skin; hot and dry tongue, coated; pulse quick and rather full; oil had not acted.

June 13th.—Febrile symptoms abated; tongue slightly coated, but soft; pulse 93; slight pain in back of head and neck; there is a hole in his forehead more than half an inch deep, over which the skin is contracting; no discharge; lint coated with healthy pus. Carbolic oil dressing continued, and cold lotion to head; ordered an ounce of castor oil, as the previous dose did not act; gets his usual diet—viz., rice and vegetables with some curry.

14th.—Interior of wound healthy-looking; has had no headache or other urgent symptoms; tongue clean; pulse regular; bowels acted freely; wound dressed as before; lotion continued.

15th.—Removed some clay from the wound, which was cleaned out with a sponge and tepid water, and dressed from the bottom as before. General health pretty good.

16th.—Wound covered with florid healthy granulations, secreting laudable pus. Health continues good.

17th.—Removed a little clay from the wound, which is progressing favourably. Dressed as before.

19th.—Cavity of the wound filling in by granulations from the bottom. Health good.

24th.—Improving.

28th.—Improving. Wound dressed as before.

July 3rd.—Cavity of the wound filling in rapidly. Same treatment continued.

11th.—Continues to improve.

20th.—Cavity of the wound almost filled in; and the man, who has continued to enjoy good health since a few days after the extraction of the bullet, has resumed his ordinary occupation, and is quite out of danger. The integument will never completely cover over the wound. A silver plate, carefully adjusted, is now all he requires.

UNIVERSITY COLLEGE HOSPITAL.

ANEURISM OF LEFT FEMORAL ARTERY IN HUNTER'S CANAL; LIGATURE OF FEMORAL ARTERY; CURE.

(Under the care of Mr. CHRISTOPHER HEATH.)

FOR the following notes we are indebted to Mr. J. W. Hunt.

W. G——, aged thirty-six, was for some years a surgeon in the navy. About a month before admission he had noticed an abnormal pulsation in the left popliteal space, but it was not till January 28th that he discovered certain signs of an aneurism. Up to this time there had been no pain in the leg and no œdema. On Jan. 31st he was seen by Mr. Erichsen, who recommended digital compression, which was commenced on the same day, and continued, with intervals, for the six following days. The periods of compression during the seven days varied from six to twenty-six and a half hours, the average length of time for each day being about fourteen hours.

On Feb. 7th the patient was admitted into the hospital, under the care of Mr. Heath. He was a strong, healthy-looking, well-nourished man. He had previously suffered from scarlet, typhus, typhoid, intermittent, and yellow fevers; the latter being accompanied with albuminuria, which had never entirely left him. There was no history of syphilis. Patient lay in bed with his leg bent at an angle less than 90°. A distinct pulsation was visible in the lower two-thirds of the left thigh, most intense at a point about seven inches above the upper border of the patella. Above this point the impulse was in a forward, and below it in a backward direction. Pulsation was expansile over an area the limit of which could not be exactly defined, but which measured approximately 4½ inches from above down, and 7¾ inches from side to side. Pressure on the femoral artery above caused an entire cessation of the pulsation. No distinct tumour could be felt. There was slight throbbing felt in the site of the aneurism. There was no œdema, and no discolouration of skin over the swelling. The only cause to which the patient could ascribe the aneurism was a severe fall about forty days before admission.

At 11 o'clock (shortly after admission) a tourniquet was applied at Scarpa's triangle, and continued till 10.15 the next morning, when, no improvement being perceptible, the tourniquet was laid aside, and extreme flexion was tried. Ordered five grains of iodide of potassium every six hours. Extreme flexion was discontinued on the morning of the 9th of February, the patient having complained of great pain in the situation of the aneurism. This pain was partly alleviated by subcutaneous injections of morphia. By this treatment the aneurism was much reduced in size, and the pulsation rendered very much less tumultuous. On the 9th, at 10.30 A.M., digital compression, sufficient to arrest entirely the flow of blood, was commenced, and continued for twelve hours. Temperature 98·8°; pulse 108. After the discontinuance of compression the tumour was certainly harder, though the limits were not diminished. On the 10th extreme flexion was again resorted to, and continued till the following morning, when digital compression was resumed and kept up for eleven hours and three-quarters, the patient suffering as much pain as before. No change was observable in the aneurism. On the afternoon of the 12th the tourniquet was reapplied; but the patient was unable to bear it more than eight hours. On the 13th and 15th digital compression was again resorted to, the leg being placed in the position of extreme flexion in the intervals, but with no good effect; and on the 17th Mr. Heath decided to ligature the artery. The patient having been anæsthetised by nitrous-oxide gas, followed by ether, Mr. Heath tied the artery in the usual way, with a strong catgut ligature, pulsation being immediately arrested in the tumour. The wound was washed out with a carbolic-acid lotion, and the edges brought together by four silver sutures, an interval of about one inch being left below for drainage. The part was covered over with cotton-wool, and the leg bandaged in flannel and fixed by sand-bags in a flexed position. At 5 P.M. the temperature of the left foot (taken between the toes) was 103·5°, and of the right 107·5° (?); at midnight that of the left was 93·5°, and of the right 97·8°.

Feb. 18th.—Pulse 108; temperature 100·8° F. Patient complains of much pain in the thigh. No pulsation to be felt in the tumour. Temperature of the two legs about equal.

19th.—This afternoon the wound was dressed for the first time. There was some offensive discharge from the lower part, and the edges were inflamed. One of the sutures was removed, and the wound dressed as before. Temperature 102·2°; pulse 124. Temperature of right foot 99·8°, of left 102·4°.

20th.—Patient complains of a great deal of pain. Expression anxious; face pale, cheeks flushed; tongue covered with thick yellow fur. Pulse rapid and weak; temperature 100°. Patient vomited a little. The discharge is purulent and offensive. There is a blush for one to two inches all round the wound, with distinct sinuous and raised margins. Two or three glands in the groin are enlarged. No pain in the back.

22nd.—Two sutures were removed yesterday, and the wound poulticed; the last suture was removed this morning. The edges of the wound are glued together with pale granulations, and are separated about half an inch. Here and there pus has escaped from the deeper parts. The blush is still red, and has extended to the middle line of the thigh behind. The thigh is swollen and tender. Pulsation has not returned since the operation. The edges of the wound were brought together with strips of plaster, and simple cold-water dressing was applied. The blush was washed with nitrate of silver, twenty grains to an ounce. The healing of the wound was retarded for some time by a burrowing of matter deeply amongst the muscles at the outer part of the thigh, which was ultimately overcome by a careful application of pad and bandage.

24th.—Patient has much improved. Temperature 98·6°; pulse 96. Blush not extended. The wound still discharges a good deal. No pulsation to be felt either in the aneurism or in the posterior tibial artery.

From this time the patient continued to improve, though slowly. The blush gradually disappeared, and the discharge grew less, the wound granulating up from below. The wound was dressed with an oakum pad.

March 11th.—The wound is reduced to a linear granulating sore, except at the upper part, where a small amount of pus can be squeezed out. The tumour is hardly to be felt.

17th.—There is still a slight discharge, but the wound is healing up rapidly. No sign of the aneurism is visible to the sight, but a slight swelling can be made out by the touch. There has been no return of the pulsation, either in the aneurism or in the posterior tibial artery. The patient left the hospital to-day.

One of the most interesting features of this case consisted in the rapid development and very indefinite outline of the aneurism; in fact, no distinct edge of the tumour could at any time be felt. The results of the various methods of palliative treatment adopted were at first promising, but, as frequently occurs, did not prove permanent, and had to yield to the ligature, which eventually proved successful.

GUY'S HOSPITAL.

CHLORAL AS A LOCAL APPLICATION FOR ULCERS.

(Under the care of Mr. R. CLEMENT LUCAS.)

ON visiting the wards with Mr. Lucas on Thursday, the 7th inst., we saw several patients on whom a solution of hydrate of chloral had been used as a local application to ulcers, and the results appeared to be sufficiently satisfactory to be worthy of record. Mr. Lucas commenced the use of chloral among his out-patients in August last, for cases of sloughing wounds and fetid ulcers, and, being pleased with the result, he has since given it a somewhat extensive trial in the wards. The effect of the local application of chloral appears to be that of a powerful stimulant and disinfectant; it has no soothing or sedative effect upon the part to which it is applied, but, on the contrary, gives rise to considerable pain, which lasts some time; nor does it, even when used over a very extensive surface, ever become absorbed in sufficient quantity to act as an hypnotic. Whether it is taken up into the circulation or not matters little, since the quantity used as a local application is so small compared with the dose administered as an internal remedy, that were the whole of the drug applied to find its way into the blood, the quantity absorbed would still be very much less than that of an ordinary sleeping-draught. Its local application is, therefore, eminently safe and free from the dangers which sometimes follow the use of opium lotion or carbolic lotions long continued. Mr. Lucas has used solutions of various strengths, that which he has found most useful being a solution of four grains of hydrate of chloral in an ounce of water. The application of a lotion of this strength is, as we have just stated, often attended with considerable smarting, which may last a quarter of an hour, but the smarting becomes less at each subsequent application. In cases where the patients have complained much of the smarting, the lotion has been diluted to the proportion of three or two grains to the ounce. The treatment of foul sloughing ulcers by means of chloral lotion has been attended with great success, the surface of the sore quickly cleansing and assuming a healthy appearance, whilst the subsequent healing has advanced with a rapidity in some cases quite astonishing.

In Lydia ward we saw a stout, florid woman, aged fifty, who had suffered from varicose veins for twenty years, and from ulcers for ten years. The ulcers for which she was admitted on Sept. 8th had been open for four years. At the time of her admission there were two irregularly oval ulcers occupying the front and outer side of the left leg. The anterior one was nearly seven inches in length, by three inches and a half in breadth; the second, situated behind this, was two inches and a half in length, by three-quarters of an inch in breadth. The surfaces of the sores were deeply excavated, and sloughing in parts, whilst the edges were thick, raised, and everted. Under the use of chloral lotion the ulcers quickly became sweet and clean, and the cuticle spread over them with very great rapidity, even while the surfaces of the sores were still considerably below the level of the surrounding skin. The smaller ulcer was completely healed within a fortnight, and at the time we saw the patient all that remained of the large one was a small fusiform patch of healthy granulations, about half an inch in breadth and two inches in length, upon which a blue line of cuticle was rapidly encroaching.

In the same ward there were several other cases of ulcers of less severity that had been treated in the same manner, which presented an equally favourable appearance, and also a case of suppurating cyst of the tongue, for which a gargle of chloral hydrate (two grains to the ounce, sweetened with syrup) had been prescribed as a disinfectant.

In Lazarus ward there is a patient who has suffered from varicose ulcers for ten years. He is a corn-porter, fifty-four years of age, and is accustomed, when at work, to drink five or six pints of beer a day, besides indulging to intoxication at least once in every week. When admitted, his legs were much swollen and inflamed, and the ulcers deeply excavated, sloughing on the surface, and reeking with offensive odours. There was an ulcer on the inner side of the left calf, two inches and a half in length by one inch and three-quarters in breadth; the edges were thick and everted; at the upper part there were high granulations, and below a sloughing surface. On the right leg there were two elongated and irregular ulcers: one on the outer side, five inches in length by two inches in breadth; and one on the inner side, four and a half inches in length and from half an inch to an inch in breadth. These ulcers were deeply excavated, and in a foul and putrid condition. After the application of chloral lotion for a few days, the sores presented a clean and healthy appearance, all putrescence and bad odour had vanished, and cuticle began rapidly to spread over their surfaces. On the 7th inst., about three weeks after admission, the ulcer on the left leg was reduced to one inch by half an inch, and was a healthy healing sore. The large ulcer on the outer side of the right leg had healed, with the exception of two small portions, one at the lower part and one in the middle; and the ulcer on the inner side of the same leg was healthy and healing, and reduced to three inches in length by half an inch in breadth.

We also saw a boy in the Accident ward who had met with a severe injury in front of the knee, causing extensive sloughing of the integuments in front of the joint. In this case chloral lotion had been used from the first, and had acted favourably in cleansing the wound.

WARNEFORD HOSPITAL.

CASE OF ARTIFICIAL RESPIRATION IN PARALYSIS OF RESPIRATORY CENTRES.

(Under the care of Dr. HOMER.)

SOME remarks were recently published in this journal on Artificial Respiration in Paralysis of the Medulla Oblongata. The following case, for the notes of which we are indebted to Mr. Geo. W. Crowe, M.B., house-surgeon, bears upon the same subject.

George M——, aged sixteen years, bandsman in the militia, was admitted on June 17th, 1875. Had been ill one month. Had been a strong lad until May 16th, 1875. On that day he marched with the band about two miles, but he complained of headache and sickness, and was sent home. Next morning he felt quite well again, marched with the band about three miles, played all day until 4.30 P.M., when he again felt so ill that he was sent home, supported by two men. He was kept in bed for one week, when he was sent to the Militia Hospital, and remained there until the date of his admission to the Warneford Hospital.

On admission, he was very weak, semi-conscious, but answered questions when roused. The body was much emaciated, and the belly retracted. Temperature 99·5°; pulse 86; respiration 18; pupils normal; urine healthy. He moaned a good deal, and complained of severe pain in back of head and neck. This was much relieved by ice-bags. He became quite conscious on the fourth day after admission, and said he did not remember coming to the hospital. Pain in the head much better. After three days the pain in the head returned, and the patient complained of pain also in the back of the eyes. He again became partially unconscious, with slight delirium at night. Got out of bed several times in the absence of the nurse. He became quite conscious again in three or four days, but again had a relapse after a few days. He continued in this state, with periodical intervals of consciousness, until July 25th. The bowels were very costive, and vomiting was a constant symptom throughout.

On the 25th of July Mr. Crowe was hastily summoned at 2.45 P.M. The nurse said that she had left the ward for a few minutes, leaving the patient rather better than usual, but on her return he seemed much worse, and was moaning a good deal, and crying as if in severe pain. The patient was found with a flushed face, and quite unconscious. The veins of the forehead were much distended, and the pupils contracted to the size of a pin's head. The pulse was full, rapid, and regular; the breathing very quiet and slow. In about a minute all respiration ceased, and the face soon became quite livid. The heart continued to beat strongly. Dr. Wilson, medical officer of health for Warwickshire, happened to be present at the time, and agreed in the decision to try artificial respiration pending the arrival of Dr. Homer. Dr. Wilson kindly assisted in maintaining artificial respiration, and in a few moments the lividity began to disappear, and in a minute the face had quite regained its normal hue. In about five minutes the pupils suddenly dilated widely, but still continued insensible to light. The artificial respiration was continued without intermission for two hours and a half, and in the meantime Dr. Homer had arrived and ordered a turpentine enema. This, however, was not retained, owing to relaxation of the sphincter ani. At this time it was noticed that there was well-marked priapism. After two and a half hours the artificial respiration was temporarily discontinued, and in two minutes the pulse had risen in frequency from 120 to 140 beats per minute. In five minutes the heart's action had become intermittent and the face intensely livid. Artificial respiration was now resumed. (During this interval it was proved by several tests that there was no attempt at natural respiration.) In one minute the lividity had quite disappeared, and the pulse fallen to 120, with no intermission. At 5.30 P.M. artificial respiration was again discontinued, and not resumed for seven minutes. The same sequence of events occurred, except that the pulse rose to 150, and there was a loud systolic bruit at the apex of the heart. At 6.20 artificial respiration was again discontinued. The pulse at this time was 116, slightly weaker than before, but still pretty strong and regular. The temperature was 96°. After seven minutes artificial respiration was resumed, and kept up for an hour. It was discontinued at 7.30, but recommenced in five minutes, as the heart's action had become very intermittent. A 7.50 it was again discontinued, and not resumed for ten minutes. In five minutes the heart's action became intermittent; it then became regular again for about a minute, and again intermittent. The beats rose in frequency till the end of the fifth minute, when they began to get slower, and at the end of the tenth minute had fallen to 48. The face became almost black, and the veins of the neck were much distended. Artificial respiration was now resumed, and the lividity again disappeared, but more slowly than on the previous occasions, as the admission of air to the lungs was impeded by accumulation of mucus in the air-passages. At 8.20 P.M., five hours and thirty-five minutes after artificial respiration had been commenced, it was determined to finally discontinue it. In three minutes the pulse fell to 60, the heart's action gradually becoming weaker, with systolic bruit, loudest at the apex. In ten minutes the heart's action was sluggish and irregular, and there were only 20 beats per minute. The heart-sounds continued audible for fifteen minutes, but after this interval no sound could be heard.

Autopsy, forty-three hours after death.—Only the head was allowed to be examined by the parents. The legs showed signs of rickets. A portion of the inner table of the skull, about the size of a shilling, was deficient, near the coronal suture. The membranes showed nothing abnormal. A small amount of fluid escaped on removing the skull-cap. The vessels were not much distended. The ventricles were all very much dilated with a straw-coloured fluid, and there was a little pus in each of the posterior cornua. The lining membrane of the ventricles showed gelatinous degeneration. The medulla and cerebellum were softer than usual, and there was a small patch of tubercle on the latter where in contact with the medulla.

Remarks.—There are several points of interest in the above case. First, that life can be prolonged for a considerable time by means of artificial respiration. In this case the patient was kept alive for five and a half hours, when in the natural order of events he would have died in a few minutes, and no doubt the artificial respiration could have been successfully maintained for a considerably longer period had not the case been considered quite hopeless. Again, this case shows that the blood can be perfectly reoxygenated by means of artificial respiration after a total absence of all respiration for ten minutes. And, thirdly, though the rule laid down is, that in cases of suffocation or non-admission of air to the lungs from other causes, the ventricular contractions cease before the expiration of five minutes, yet, in the above case, the last ventricular contraction was fully fifteen minutes after all respiration had ceased.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

This Society met for the first time after the recess on the 12th inst., when the chair was taken by the President, Sir James Paget. The attendance of Fellows and visitors was unusually large, attracted, doubtless, by the paper of the evening, which occupied upwards of an hour in delivery. The subject of the paper was the Pathology of Chorea, and it will be seen that Dr. Dickinson does not accept the theory of embolism, and that he describes widespread changes—chiefly of hyperæmic nature—in the nerve centres similar to those which he has met with in diabetes. The meeting was prolonged for half an hour, which allowed of the delivery of excellent speeches by Drs. Broadbent, West, and Hughlings Jackson. At the commencement of the proceedings, the President laid upon the table the new volume of the Society's Transactions. We observe that there is already a very long list of papers to be read in the coming session.

A paper by Dr. W. H. Dickinson on the "Pathology of Chorea" was read. At the outset the author remarked upon the need of accumulated observations in the present state of the pathology of the nervous system, before it would be possible to know the progress of any disease from its origin to its termination. He then proceeded to describe the morbid appearances found in seven fatal cases of chorea. The cases were related, as nearly as could be judged, in the order of their acuteness, those being placed first in which death ensued earliest.—Case 1. A girl aged ten years, had acute rheumatism one month before; systolic murmur at apex; no palpitation, but pain in left chest and spine. The attack of chorea lasted two days, terminating somewhat suddenly, death being preceded by acute pain in lumbar region. There was found thickening of edge of mitral valve, with vegetation on its auricular border. Intense injection, both arterial and venous, in brain and cord, most marked in the corpora striata, the arbor vitæ of the cerebellum, and in the dorsal region of the cord. Traces of perivascular erosion widely distributed, and the central canal of the cord was greatly dilated (measuring one-seventh of an inch in diameter in the lumbar region), and distended by débris of blood and by serous exudation. — Case 2. Girl aged ten years — third attack, the first of which, four years previously, had been very severe. The present attack lasted twenty-one days, the temperature reached 104·5°, and there was a faint systolic murmur. The mitral valve was beaded. In the nervous centres there was similar evidence of congestion, both arterial and venous, especially in the corpora striata, with the addition of superficial hæmorrhages, and exudation around the arteries of the corpora striata. In the cord, besides injection, there were numerous periarterial erosions in the dorsal and lumbar regions, especially in the grey matter.—Case 3. A boy aged seven; death on the twenty-fourth day. Vegetations on mitral valve. Injection of vessels of brain of every class, most about optic thalami; some extrusion of corpuscles. Injection of cord, and hæmorrhage into grey matter of dorsal and lumbar regions, symmetrically with regard to the two sides.—Case 4. A girl aged eight; chorea following fright received three days before; no cardiac murmur; death in a typhoid condition fifty-seven days after the fright. Engorgement of veins of brain, chiefly on surface and in substance of corpora striata. Injection and erosion of the cord, with large hæmorrhage (visible to naked eye) in the anterior cornu in the cervical region, and smaller hæmorrhages elsewhere.—Case 5. Duration fourteen days. Venous injection of brain, especially of corpora striata, wherein were also periarterial exudations. Arteries in convolutions near Sylvian fissure, surrounded by blood-crystals and débris. Injection and scattered erosions of cord. "Sclerosis" of grey matter in dorsal and cervical regions, placed with bilateral symmetry.—Case 6. Female, aged fifty-four; since last attack, thirteen days; two preceding attacks, the last a year ago. Recent injections, such as in other cases, of bodies at floor of lateral ventricles and of cord. Older changes, periarterial degenerations, and scattered spots of "sclerosis" in *substantia perforata*, and convolutions at beginning of left Sylvian fissure.—Case 7. Duration four years. Spots of "sclerosis" numerously set in *substantia perforata*, and grey matter of corpora striata, symmetrically with regard to the two sides. In cord, large exudations into the grey matter and fissures, chiefly in the cervical region. In speaking of so-called "sclerosis," the author pointed out that the term was misleading, since there was no induration, the change consisting in small round or oval translucent spots, about one-hundredth part of an inch in diameter. Having given the above summary of fatal cases, he stated that it was enough to show that the changes were remarkably constant in kind and place. In *kind* the changes were all (allowing sclerosis to be so) directly connected with vascular disturbance. The injection was general to vessels of every kind, but most marked in the arteries; when the sources of exudation or of hæmorrhage could be determined, they were always arterial; the degenerations were usually periarterial, and the spots of sclerosis similarly placed. The first visible change would seem to be injection or distension of the arteries, this being succeeded by extrusion of their contents, to the irritation or injury of the surrounding tissues. In *place* the changes affected both brain and cord; the cord perhaps the most severely. Whether in brain or cord, the changes on the two sides were generally symmetrical, both being often affected at the same spot in the same manner, and nearly to the same extent; and in instances where no symmetry was apparent, a tendency to it could be traced, as in the existence of vascular distension on one side corresponding to hæmorrhage on the other. The parts of the brain most usually attacked lay between the base and the floor of the lateral ventricles in the track of the middle cerebral arteries—the substantia perforata, the corpora striata, and the beginning of the Sylvian fissures. In the cord the changes attained their maximum in the posterior and lateral parts of the grey matter and in the upper portions of the cord. Regarding arterial repletion as the origin of the pathological changes, the source of this vascular state was discussed. The embolic theory was shown to be inconsistent with the character and distribution of the morbid appearances, in that in no instance were decolorised plugs found in the arteries, and the symmetrical distribution of the changes was strongly opposed to embolism. To elucidate some of the points in question, the clinical history of the disease was adduced as represented by a tabulation of 22 fatal cases, all examined after death, and 70 cases under observation during life only. The prominent fact brought out by these cases was the frequency of mitral endocarditis in connexion with the disease. This existed in 17 of the 22 fatal cases, while there was stethoscopic evidence of it in 40 of the 70 non-fatal cases. It was thus shown that endocarditis was associated with chorea independently of the frequent origin of the chorea in rheumatism, and when the nervous disturbance could be definitely traced to mental causes. Thus, while in rheumatic cases endocarditis often preceded the chorea, it was equally evident that chorea in other circumstances preceded and caused the endocarditis. This duplex relation between the nervous and the cardiac disorder was discussed, with the conclusion that chorea was not in any way, either embolically or otherwise, a result of endocarditis, though often associated with it as having a common origin in rheumatism; while endocarditis was continually a result of chorea, set up possibly by the muscular irregularity of the heart and the mitral regurgitations thereby occasioned. In conclusion, chorea was regarded as depending upon a widely-spread hyperæmia of the nervous centres, not due to any mechanical mischance, but produced by causes mainly of two kinds, one being the rheumatic condition, the other comprising various forms of irritation—mental and reflex—belonging especially to the nervous system. Given the irritant, mental, reflex, or rheumatic, the course of the disease had been sufficiently traced in hyperæmia and its results. The spots of perivascular change were widely scattered through that large region which lies inferiorly to the cerebral convolutions, between the corpora striata and the lower part of the cord, the district of the motor and sensory as distinguished from the mental functions. The result, chiefly in muscular excitement rather than in paralysis or loss of sensation, was associated with the character of the lesions which were points of irritation rather than planes of sections, and calculated not so much to cut off as unnaturally to excite nervous function. In looking at the nature of the lesions, proceeding, as they do, from vascular distension to perivascular change, it was not possible but to connect them with those of a large group of nervous disorders, prominently with those of diabetes. In diabetes the changes are of similar origin and character, though usually seen at a later stage, and attended with more excavation. They are, however, somewhat differently disposed in the two disorders; in both they are widely distributed, in diabetes the stress falling upon the brain, in chorea upon the cord. Every period of life has its own region of nervous susceptibility: in childhood the motor; in adolescence the emotional; in advancing years the mental, and, coevally or nearly so, that part of the nervous mechanism which instigates glycosuria. Much the same mental impression may make a child choreic, a girl hysterical, or a man diabetic; and thus, both in external origin and in the nature, though probably not in the site, of the organic changes, we see resemblances and alliances between nervous disorders which in their symptoms betray little similarity.

Dr. Broadbent said that, whereas Dr. Dickinson would define the pathology of chorea as a generally distributed hyperæmia of the nervous centres, and especially of the cord, yet he (the speaker) would rather localise it in the corpora striata. No mention had been made in the paper of derangement of sensation, which is often diminished to a considerable degree in hemichorea, and probably much lowered in the general form, since the patients often endured the formation of bedsores without apparent suffering. Then, in bad cases of chorea, there was often violent delirium, and this with a low temperature, and, in some cases, aphasia. All these variations showed a variability in the site of the hyperæmic condition. Hemichorea, which is perfectly parallel to hemiplegia, cannot be supposed to depend upon changes limited to one-half of the cord; moreover, the anæsthesia in these cases was on the *same* side as the chorea, and not on the opposite side, as it would be were the origin of the disease spinal. There was no increased reflex excitability in chorea. Then there were cases of hemichorea followed by hemiplegia. Dr. Dickinson's cases themselves showed that there was frequently a limitation of the most marked changes to particular regions. As regards the embolic theory, Dr. Dickinson seemed to have overlooked the fact that the embolism is capillary, and he (the speaker) remembered one fatal case of rheumatic chorea with delirium in which there was plugging of minute vessels of brain with decolorised clots. Too much stress had been laid upon the irregularity of the heart, which he thought was rather secondary to irregularity of respiratory action, and he could not see how such irregularity could give rise to endocarditis.—Dr. West, after eulogising the labours of Dr. Dickinson, thought that at present we were not in a position to establish, from pathological observation alone, the nature of a disease in which the mortality was so small as 1 per cent. He himself had only seen four autopsies. The conditions described were not peculiar to chorea; much the same changes were found in trismus of new-born infants; and, on the other hand, there were cases of chorea in which such appearances have not been observed. He questioned whether chorea could be fairly considered as rheumatic independent of the cardiac disease, and he would rather connect the chorea with the endocarditis than with rheumatism. Rivière had drawn attention to the fact that whereas in Geneva rheumatism was frequent, chorea was rare. The very frequent association of endocarditis with rheumatism must be borne in mind. Occasionally, too, chorea is followed by rheumatism. Then, even in slight cases of chorea, there was sometimes long-continued mental enfeeblement long after the cessation of the choreic movements.—Dr. Hughlings Jackson said that although doubtless

Dr. Dickinson's able paper would draw away many from the view that embolism was the cause of chorea, he himself still maintained that view. In two cases he had found emboli in the small arteries, but it was right to add that he was aware of two other cases in which no such lesion was found. Dr. Bastian had found plugging of small arteries (which he attributes to thrombosis) in the corpus striatum in three cases. He thought that the pathology of chorea was still an open question, and was glad to find Dr. West expressed the same opinion. But there were many arguments in favour of embolism. Thus it is the very process which could cause that unstable or excitable condition of the nervous system present in the disease. There were constant nervous discharges, showing that the nervous tissue was intact, and even more active than in health. Now embolism, it is known, leads to a hyperæmia, so that more blood was supplied to the nerve-cells. Thus, "red softening" was due to embolism, and the appearances of red softening could be produced by the injection of tobacco seeds into the carotid, as had been done by Prevost and Cotard. This increased vascularity could be well seen in retinal embolism, so that the process of embolism would lead to changes similar to those described by Dr. Dickinson. Passing to the question of *fright*, Dr. Jackson said it must be considered as an exciting cause in a subject already predisposed. Surely the great frequency with which chorea was associated with rheumatism and endocarditis favoured the view of embolism, just as it would in a case of hemiplegia occurring in a young adult without loss of consciousness. Chorea in adults was frequently met with in pregnancy, a condition favourable to thrombosis. The clinical objection raised by Jaccoud and Anstie, that *left* hemichorea was more frequent than *right*, was not a serious one, since other observers had reversed this relative frequency. The prompt recovery from chorea had been advanced as against the embolic view; but did not patients with severe hemiplegia, depending on widespread lesion in the brain, often recover promptly and almost completely? This recovery he had before explained on the "principle of compensation," which had been recently invoked by Carville and Duret to explain the absence of paralysis after removal of certain motor centres in the brain, and Charcot had used the same explanation in a case of recovery from hemiplegia. The resemblance of hemichorea to hemiplegia was very great, both in the order in which the various parts were affected and in which they recovered, and there was defect in talking (aphasia) in right-sided chorea. That the face was affected first negatived the seat of origin being in the cord. He would, however, state a few of the facts that had been advanced in opposition to the views he held. Dogs are liable to chorea, and several independent observers have noticed that if the spinal cord be divided *above* the choreal limb of a dog the movements still persist. But it must be remembered that in the dog it was probable the centres of voluntary movement extended lower down than in man. The changes described by Dr. Dickinson were not inconsistent with the theory of embolism. In chorea the seat of the lesion was probably in the corpus striatum—the chosen spot for embolism.—Dr. Dickinson briefly replied, pointing out that there were certain spots both in the brain and cord which were specially and constantly affected; that the symmetrical distribution of these was a strong argument against the embolic view. He also affirmed that he had examined the vessels in a recent state, and had failed to find any minute emboli; and these, if present, should by reason of their minuteness be widely diffused. Further, chorea will occur independently of heart affection.

CLINICAL SOCIETY OF LONDON.

This Society met on the 8th inst., Sir W. Jenner, K.C.B., President, in the chair. At the commencement of the proceedings the President laid upon the table a copy of the Society's Transactions, vol. viii. The papers read were not productive of much discussion; they included a lucid description of a New Form of Iridectomy by Mr. B. Carter, the Notes of a Case of Idiopathic Tetanus by Dr. Southey, and contributions to Antiseptic Surgery from the hands of Mr. Callender and Mr. Pick.

The first paper read was by Mr. Brudenell Carter upon the "Operation of Iridectomy as performed for Optical Purposes." Mr. Carter said that he had brought several patients for exhibition to the members of the Society, in whom he had performed an operation for admitting light into the eye in cases of leucoma, central opacity of the lens, &c., where the ordinary operation, as performed for the relief of tension, is unsuitable, because of its leaving too large a gap, and thus admitting a superabundance of light to the retina, and also because of its leading to spherical aberration by uncovering the margin of the lens. Even when a very small portion of the iris is excised the artificial pupil is still too large for good vision. The principle, then, of the modified operation is to make an incision outside the corneal margin, and to incise the iris from within outwards, leaving the outer rim of the iris intact. In that way a **V**-shaped pupil is formed. At the International Ophthalmological Congress held in London in 1872, Mr. Bowman advocated a similar operation, which he performs by introducing a small knife, shaped like a spatula, sharpened on one edge, through a puncture made by a broad needle opposite the intended pupil; then, turning the edge forwards, he incises the pupillary edge of the iris, cutting against the cornea. A small incision into the posterior surface of the cornea might be made, but is unimportant; there is, however, great risk of cutting the capsule of the lens. Bowman's operation has been modified by M. Wecker, who calls it "iridotomy," in which he uses a pair of scissors furnished with forceps-handles and blades like Bowman's knife. Introducing the scissors into the anterior chamber as in Bowman's operation, M. Wecker passes the scissors across the pupil, then slightly opening them, so as to enclose the iris between the blades, the pupillary edge and circular fibres are divided, and the scissors withdrawn. But the risk of injury to the lens is greater in this operation than in Bowman's. Mr. Carter has, therefore, adopted a further modification, by which this risk is obviated. Using Wecker's scissors, he makes a small incision in the sclero-corneal junction as far back as possible, and *on the same side* as the intended pupil. The closed scissors are then introduced as far as the pupillary margin, and the iris rising up (as it always does in iridectomy) is caught, by a turn of the instrument, between the scissors-blades, and a very minute portion, of a triangular shape, excised. Mr. Carter stated that he had now performed the operation on thirty eyes (two single and fourteen double operations). To avoid injury to the lens, the ends of the scissors are directed towards the cornea. In one or two of the earlier cases there was slight tendency to prolapse of the iris; and at first he used fine iris-forceps to remove the excised portion, but latterly he has removed this with the scissors. The advantages of this operation consist in (1) a single instrument being used for the excision after the preliminary puncture; (2) the iris being incised *in situ*, and therefore not seized or bruised in any way; (3) there being no difficulty in regulating the breadth of the piece removed, and therefore the size of the new pupil. As an operation for the relief of tension it is valueless. The paper was illustrated by diagrams.—In answer to Mr. Norton, Mr. Carter said that the cases selected were not those necessarily with any retinal affection, but they were all severe cases.—Mr. Spencer Watson thought that there would be less disfigurement if the direction of the pupil passed upwards and inwards, and not downwards as in the diagram.—Sir W. Jenner pointed out that the object of the paper was rather to show the mode of operating than the situation of the pupil; a statement which was confirmed by Mr. Carter, who said that the pupil might be made in other situations if necessary.

Dr. Southey then read notes of a "Case of Idiopathic Tetanus." The patient, a railway ticket-collector, twenty years of age, began to suffer on June 16th with pains in limbs, stiffness in back, and inability to open the mouth. Two days previously he had got wet through. On the 17th he had an attack of opisthotonos, which recurred two or three times a day up to the 28th, when he was admitted into the hospital. He had been taking chloral and stimulants. He was a well-nourished, muscular man, and when admitted had a slight risus sardonicus; could only open the jaws by an eighth of an inch; the neck muscles were stiff, those of abdomen flaccid. He could not move arms nor legs, and had much aching pain in back and calves of legs. General hyperæsthesia. Mere exposure of surface to air provoked opisthotonic spasm. Temperature 100° F.; pulse 120. Was ordered calomel and opium, and a draught containing a drachm of bromide of potassium with ten grains of chloral, to be taken every three hours; no stimulants. There was constipation, a large amount of phosphates in urine, but no albuminuria. On the next day (29th) the temperature was 99·2°, and pulse 94. He had five attacks of opisthotonos between 3 P.M. and 8 P.M., each spasm lasting about five minutes, accompanied by profuse sweating. He was then prescribed two drachms of succus conii with half a drachm of the bromide every three hours, and his bowels were opened by enemata. The attacks remitted till 8 A.M. next day, when they recurred with violence, and were accompanied by much pain. On this day he was swathed in flannels and poppy fomentations, which were ill borne, and were replaced by a tepid bath every night. Improvement dated from July 2nd, and on the 8th he was quite recovered. Dr. Southey remarked that the opisthotonos was as severe as in traumatic tetanus. The decline of the disease was, like the invasion, gradual, the muscles of the neck, which were the first to be affected, being also the first to assume the normal state. The bowels first began to act on the remission of the symptoms, and this Dr. Southey thought was of importance, the return of peristalsis being regarded as one of the earliest evidences of the declension of the disease. When admitted the patient was restless and excited, evidently suffering from the effects of chloral and alcohol. He improved under the bromide and conium, and Dr. Southey referred to the action of the salt upon frogs, producing cutaneous anæsthesia. Wood records sixteen cases of tetanus treated by bromide of potassium, of which nine were traumatic and recovered; while of the seven idiopathic two only were fatal. The conium, too, is known to diminish or destroy the conducting power of the motor nerves, so that both drugs probably combined to restore the normal state.—Sir WM. JENNER pointed out that the date at which the drug was first commenced—viz., the twelfth day of the disease—was late, and near the termination of ordinary cases, which was stated by Dr. Southey to be fourteen days, although some cases were fatal in the third week. Sir William also pointed out that the quantity of succus conii given was small in comparison to the large doses used by Dr. J. Harley with impunity.—Dr. CAYLEY mentioned a case of severe spasmodic torticollis which had been recently under his care, in whom two ounces of the ordinary hospital preparation of the succus produced no effect; and to produce the full effects of the drug, two ounces given in increasing doses up to two ounces and a half of the succus specially prepared were requisite.—Dr. JULIAN EVANS stated that Ambrose Paré records a case of tetanus successfully treated by a warm bath, in which the patient was kept for fourteen days.—Dr. BURNEY YEO thought that the author had done scarcely sufficient justice to the value of purgatives, which might be of value in the same way as counter irritation was useful; and he recalled a case in which hypodermic injection of chloral was employed, with the result that the spasms were cured as the seats of injection suppurated and multiplied. The patient, a boy, had his body covered with scars.—Sir W. JENNER said that here, again, it was of the utmost importance to know the date at which the remedial measures began to take effect, as the apparent benefit following them might be really due to the natural course of the disease; and Dr. YEO said that he hoped to bring the case before the Society.—Dr. SOUTHEY, in reply, said that the temperature was never very high, which showed it to be a mild case. Although he had tried it with bromide of potassium, he would feel sceptical as to the efficacy of any single mode of treatment in every case. He certainly did not think purgation of value, and thought that the great object was to keep the skin from exposure to cold and external irritants; and if the bromide does indeed diminish the irritability of the spinal cord, the *rationale* of its use was manifest.

A short paper, communicated by Mr. CALLENDER, was then read by the Secretary. It was entitled "Experiences with Salicylic Acid." The author had tested the value of this antiseptic in many cases of surgical wounds and injury, and a variety of preparations had been employed, the most frequent of which was an aqueous solution (one in fifty) with phosphate of soda, a solution in olive oil (one in fifty), and an ointment. A preparation of the acid with mastic and spirits of wine was also used. A brief outline of seven cases was given. (1) Free incision for disease about the hip; wound washed out with salicylic acid in spirit, and on the eleventh day dressed with the ointment on Japanese paper. A vesicular eruption followed. (2) Caries of metatarsal bone of great toe; washed out with the acid. Caused considerable local irritation. (3) A wound which, dressed with the acid, took long in healing, and surrounding skin became seat of vesicular eruption. (4) Similar to (1), the effect of the acid being to produce some constitutional disturbance as well as local irritation. It was replaced by carbolised oil. (5) Excision of elbow; wound washed out and dressed with acid. (6) Lacerated wound of forearm; first treated with carbolic acid, and then with salicylic. (7) Operation for relief of neuralgia. These latter cases healed fairly well. Mr. Callender concludes that salicylic acid is of value because it is free from odour, because wounds heal under its influence and usually without local pain; but that it acts as an irritant and gives rise to constitutional disturbance when the solution used is over 2 per cent. in strength. It gives rise to more discharge than carbolic acid does, and repair of wounds is not so rapid under its use. It is then inferior to other antiseptic agents now employed.—Sir W. JENNER related the case of a lady who had an extensive burn, which was dressed with salicylic acid. Soon afterwards a scarlatinoid rash appeared, and faded on the dressing being left off, but returned when this was renewed. At the same time there was much constitutional disturbance. The acid was effectual in destroying the fetor.

Mr. PICK read notes of a "Case of Extensive Wound of the Knee-joint, treated antiseptically." The patient, a sawyer aged eighteen, wounded his left knee with a saw, dividing the patella longitudinally and grooving the end of the femur. The halves of the patella separated widely, exposing the joint. The wound was sponged out with carbolic acid, and, the edges being brought together with catgut suture, the wound was injected with carbolic lotion (1 in 40). Several layers of carbolised lac plaster were applied, and the limb supported in a cradle. There was some febrile reaction, and on the third day the dressings were renewed under the carbolic spray. There was little or hardly any discharge. There was effusion into the knee-joint, which subsided rapidly. Progress was slow, somewhat delayed by burrowing of pus behind the leg. The discharge was very free and copious, but always inodorous. The patient was discharged in July, 1872, about four months after the accident, anchylosis having taken place. He was seen in May of the present year; there was firm bony anchylosis. Mr. Pick remarked upon the usual statement that compound fracture of the patella offered no resource but amputation; but Mr. Poland had given a more encouraging opinion. Certainly in the present case the man was better off with a stiff joint than an artificial leg, and, besides, he had not run the risks of amputation, which were greater than those of conservation. Mr. Pick concluded by pointing out the value of Lister's antiseptic method in such cases, and expressed his full confidence in it.

The hour for adjournment having arrived, the discussion on the papers of Messrs. Callender and Pick was postponed until the next meeting.

THE MEDICAL SOCIETY OF LONDON.—The Fothergillian Gold Medal, value twenty guineas, is offered annually for a dissertation on some subject connected with Medical Science, for which the learned of all countries are invited to become candidates. The subject selected for competition in March, 1876, is on "Cataract and its Treatment"; for March, 1877, on "Pyæmia." Essays, which must be in the English or Latin language, and not in the handwriting of the author, must be delivered to the Registrar, at the Society's house, on or before Nov. 1st preceding. With the dissertation must be delivered a sealed packet, having a motto or device on the outside, and within the author's name and designation. The same motto or device must be inscribed on the dissertation. The successful essay becomes the property of the Society.

Reviews and Notices of Books.

Cyclopædia of the Practice of Medicine. By Dr. H. VON ZIEMSSEN. Vol. X: Diseases of the Female Sexual Organs. London: Sampson Low and Co.

THE physiology of the organs of generation in the female is still an obscure subject. From the time when the law of spontaneous discharge of ova was enunciated and established, and when the formation of the decidua vera from the mucous membrane of the uterus was proved by observation in histology, to within the last three or four years, little or no progress had been made in this branch of science. During the same period, the advances made in the pathology of the organs were few and small; indeed, with the exception of those made in our knowledge of the formation of ovarian cysts, they have been almost entirely limited to morbid histology. On the other hand, observations made at the bedside in the diseases of the sexual organs have multiplied rapidly. Workers have been numerous, and the number of facts gathered together under this head is very great, far in excess of the number of those in the corresponding branches of physiology and pathology. For this reason the views held on various subjects in connexion with the diseases peculiar to women are very different and even opposing, and this diversity of opinion will continue to prevail until further researches into the physiology and pathology of the organs shall have elucidated many points which are now the subject of mere conjecture. For the same reason it is not possible, in the present state of our knowledge, to give a full and systematic account of the disorders of the female organs of generation except from a clinical standpoint.

The work before us opens with a chapter on "Gynæcological Examination," which is one of the best written on the subject. The value of the various means of exploration are well given, especially that of the sound, the bimanual method, and examination through the rectum. The use of the sound has been properly limited, and accurately defined, and the bimanual method has had assigned to it the prominent place it demands.

Malformations of the vagina and of the uterus are treated of in a full and clear manner, and this part of the work leaves nothing to be desired.

Flexions are treated of briefly, though the author assigns to them a very important position in the disorders of the female organs of generation, for he goes the length of treating such displacements even when they present no symptoms. The etiology of anteflexion is summed up as follows:—"Anteflexion occurs in multiparæ as a congenital excess of a physiological state; it also occurs in women who have borne children when, in a normal or relaxed state of its tissues, the uterus is exposed to any great and repeated increase of the abdominal pressure." Reposition of the displaced uterus should be done by the hands alone, but should this be found impossible, the use of an "intra-uterine pessary" is recommended. This is a stem with a knob at one end. The stem introduced into the uterus converts the flexion into a version; the knob is then, in retroflexion, pushed back towards the sacrum so as to carry the fundus upwards. This is similar to Sims's method, with the exception that the hand is used as a handle. It has the further advantage in the hands of Schroeder, who favours the use of stems in the treatment of flexion, that the instrument used for reposition serves as a pessary; for, having reduced the malposition, he leaves the stem in the uterus, and maintains it there by pledgets of lint. He regards the above method as "very efficient," and "not particularly dangerous." At the same time he admits that a relatively small part of flexions can be so treated, but adds that the displacement, as such, in the majority of cases, does not admit of permanent cure.

Our author adopts Waldeyer's view of cancer, regarding it as an epithelial growth of local and not constitutional origin, the varieties of the neoplasm depending on the different proportions of epithelial and connective tissues entering into its composition. He points out the difficulty of recognising cancer in its earlier stages, as well as the fact that the disease is generally in an advanced condition—frequently ulcerated—before medical advice is sought; consequently that the period for attempting a radical cure has passed, as a rule, before the diagnosis is made. When, however, the affection is recognised in its earlier stages, an attempt should be made to remove it entirely. This should be done by the galvanic cautery or the wire écraseur, but never by the chain écraseur, inasmuch as the latter is liable to drag into its grasp too much of the neighbouring tissues, and thus lay open the peritoneum. When the above instruments are inapplicable, the sharp scoop should be used, after the manner of Simon. The knife and scissors should be avoided, as the patients cannot bear the loss of blood which accompanies operations performed by these instruments. After the removal of the growth the actual cautery or some caustic should be freely applied. Of the latter, Shroeder favours an alcoholic solution of bromine, which he believes has a specially destructive action on the "epithelial nests."

The views of Shroeder on hæmatocele are more or less known in England. He says: "True hæmatocele is produced by a free hæmorrhage into the cavity of the abdomen only when the blood is derived from some spot deeply situated, and when the hæmorrhage is slowly continued or repeated at intervals." The pathology of this affection, as well as that of many other uterine diseases, is still doubtful. We do not think there is any advantage in limiting the term in this manner, inasmuch as it expresses symptoms only, and not a disease. Besides, there are other conditions not included in the definition which give rise to similar symptoms, and clinically it is impossible to distinguish them.

The clinical part of the work is not so full as we would wish or expected. The pathological part is much more satisfactory. The author has throughout the work confined himself to stating his own views, not even hinting at the existence of others. In a work of such pretensions as Ziemssen's Dictionary of Medicine we cannot help regarding this as a very great drawback, for any work pretending to treat fully of the diseases peculiar to women must, in the present state of our knowledge, not only state the views held by the author, but discuss others; for, as we remarked above, diversity of opinion must, in the present state of pathology and physiology, prevail on many important matters in connexion with the diseases of the female generative organs, and the views of any particular author alone can represent the subject but very imperfectly. Further, the work lacks in details. We know that the success of a physician greatly depends on minutiæ; especially is this the case in operations and their after-treatment. In this work these helps to success are, in our opinion, passed over much too lightly. The treatise is written from a pathological standpoint, and the clinical part has consequently suffered.

The work of the translators has been, on the whole, well done. The greater part has been rendered into good and readable English. Some parts of it, however, are disfigured by too literal a rendering of the original, and by the introduction of newly and unnecessarily coined words, which, it is hoped, will not become current. We rise from the perusal of the work with a feeling that works recently issued from the English press still hold the highest position as treatises on the Diseases of Women.

The Student's Guide to Osteology. By W. W. Wagstaffe, B.A., F.R.C.S. London: J. and A. Churchill. 1875.

The appearance of this volume is most opportune, and it should be in the hands of every first-year's student. The study of osteology, being the first that is encountered by the medical student, is too often made wearisome and uninteresting by the dry and bare descriptions of the bones in many of our anatomical text-books. Mr. Wagstaffe has most successfully combated this tendency to degenerate into bare enumeration of the named parts of a bone, of their muscles, and so forth. The plan of the work is a model of systematic arrangement. At the head of each description are placed the French and German synonyms of the bone about to be described, and the description that follows deals in order with the situation of the bone, its shape, the enumeration of its various parts, its articulations, its development, mechanism, and structure, terminating with a summary of the chief points of importance to be remembered about the bone. Many practical details are introduced, while at the end of the work a section is devoted to "bony landmarks," a most valuable addition to the book. One of the most striking features consists in the section on the mechanism and structure of the bone under review, which certainly adds greatly to the interest of the description, aided as it is by well-executed diagrams. Selecting at random one of these descriptions, which may be taken as an example of what is to be found in other parts of the work, we find under the Tibia the following account of its mechanism:—

"We observe, with regard to the tibia, that it has to support the weight of the body entirely, and hence is constructed mainly for strength. We notice that each end is pyramidal, the upper pyramid being inverted. Each of these is porous, while the intervening column is composed of a dense hard shell, and is prismatic in shape. The bone is curved for greater elasticity, and is moulded in a spiral form, which also adds to its power of resistance. The curve is seen at the junction of the middle and lower thirds, and it is here that the bone bends in rickets, and when the tie-rod or fibula is deficient, it is here that the tibia gives way. Diseases, also, such as nodes and necrosis, more often attack this than any other part of the bone."—p. 111.

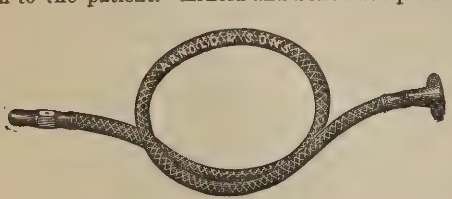
Then follows an account of the internal structure of the tibia, showing the arrangement of the fibres of the cancellous tissue in the ends of the bone. In his directions for "placing" a bone, we notice that although Mr. Wagstaffe generally gives directions as to holding the bone in its position in the body, he always refers to some part of the bone as pointing to or from the side to which it belongs. We are a little sceptical as to whether this is the best way of teaching here, although it is certainly shorter than the other method—namely, a recapitulation of three of the surfaces.

The illustrations are most numerous and exceedingly well done. Every bone is fully figured in the plates, with which the work abounds, and the attachments of muscles are marked by red lines—the origins by continuous, and the insertions by interrupted lines. We cordially recommend the book to all teachers and students, who will alike find it to be a valuable guide.

New Inventions.

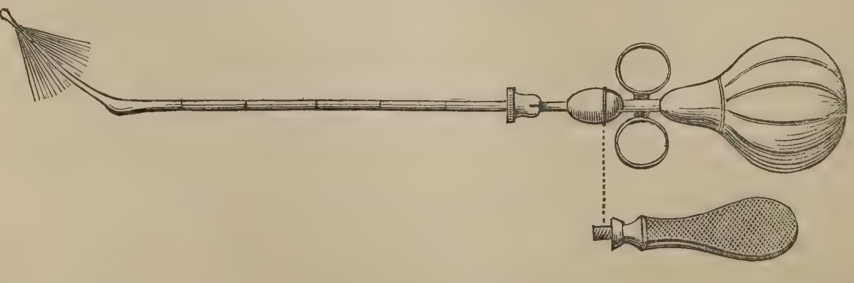
A FLEXIBLE CLINICAL STETHOSCOPE.

Every practitioner has occasion to feel often the need of a longer instrument than the ordinary stethoscope, and one which by its flexibility permits him to vary his position with relation to the patient. Arnold and Sons have produced a flexible stethoscope which meets this want. (See figure.) Its novelty consists not so much in its length and flexibleness as in its ear-piece, which is made of well-polished vulcanite, and is so shaped as to fit the meatus of the ear. Moreover, the ear-piece has a small perforation on one of its sides, which is intended to prevent the air from impinging unpleasantly upon the membrane of the tympanum when the chest-piece is moved or first applied. On commencing to listen the perforation is to be closed with the finger. We are not clear that the instrument conducts sound better than the ordinary stethoscope, but its utility in certain circumstances of frequent occurrence is obvious.



NEW COMBINED SOUND AND SYRINGE FOR UTERINE PURPOSES.

A combination of uterine sound and syringe is a desideratum which has been found in use most convenient. The instrument of which we give an engraving can be used as an ordinary uterine sound; but when, as in many cases, it is desirable to introduce fluids into the cavity of the uterus, the combination will be found extremely convenient, inasmuch as the douche can be effected without the necessity of removing the sound. The sound is hollow, and has a bulbous extremity to facilitate introduction; it is perforated diagonally, so that the fluid flows in the reverse direction and douches the entire extent of the uterine cavity. The instrument is very neatly constructed by Messrs. Salt and Son.



THE LANCET.

LONDON: SATURDAY, OCTOBER 16, 1875.

THERE is, perhaps, no question of practice or of theory that has received more consideration and attention alike from practical surgeons and medical theorists than that of antiseptic surgery; and there is certainly none that has received more varied or more conflicting answers. Almost everyone pretends to have given the subject a more or less full and careful consideration; but there are few who have entered upon the inquiry with a mind so perfectly free from bias that they could see things as they really were. It has been, and unfortunately still is, too common for those who undertake the investigation of the principles or the practice of so-called antiseptic surgery to assume at once, unconsciously it sometimes may be, the character of partisans. This person has faith in the theory on which the antiseptic system of dressing is based, and he ascribes all success to its adoption, and every failure he charges to the neglect of some detail; another may believe the theory, but fails to perceive any practical benefit from its application; others, again, while they are willing to concede that the practical advantages of the particular mode of dressing are great, reject the germ theory as not proven, and attribute the good results that are said to follow this mode of treatment to cleanliness or care, or, in fact, to anything but the special and peculiar nature of the dressings. There is yet another, and perhaps a larger, class of persons who, failing in the practice, have not been careful to discuss the theory. Many of the most successful surgeons of the present day have, after a trial more or less prolonged of Mr. LISTER's plan, gradually given it up, and resorted to the older and well-established modes of practice on which experience has taught them that they may exclusively rely. How is it that the evidence of the special value of antiseptic surgery, which is, apparently, easily obtainable, is so conflicting? The answer is not far to seek. Mr. LISTER and his disciples are themselves to blame for much of the obscurity that overshadows this question, inasmuch as they have never yet openly and fairly met the challenges that have been thrown out to them to produce the statistical results of their practice for, say, five or six years past. From time to time isolated cases, or isolated sets of cases, very successful as far as they went, have been published in our columns and elsewhere; but a few cases here and there prove nothing, and may at any time be matched by similar cases equally successful in which the antiseptic mode of treatment had not been used. It has been very pertinently remarked that if the special merits of Mr. LISTER's plan were really as great as they are alleged to be, they should at the expiration of eight or ten years have declared themselves with overwhelming force and certainty. If the antiseptic system were really all that it is claimed to be, not the shadow of a doubt of its immense superiority over every other system should now exist. But the reverse is the case. Notwithstanding the very able papers on the recent improvement in the details of antiseptic surgery which Mr. LISTER lately published in our columns, followed as they were by the demonstrations at Edinburgh at the meetings of the British Medical Association, there is less antiseptic surgery practised in the metropolitan hospitals than ever there was. There are even rival systems, apparently equally successful, which are founded on principles quite at variance with those on which Mr. LISTER's method is based. Mr. LISTER does not exclude the air, but he attempts to exclude, or rather to destroy, all the organic particles which with his mental eye he sees darkening the air and infecting everything with rottenness and putrefaction. Dr. HUMPHRY, of Cambridge, on the other hand, has been very successful with his system of open treatment of wounds; and Professor SPENCE—Mr. LISTER's colleague at Edinburgh—has had most enviable results in spite of persistently rejecting the antiseptic plan of treatment. Mr. CALLENDER, of St. Bartholomew's Hospital, has obtained brilliant results by means of cleanliness alone. It is, therefore, nothing to the point that Mr. LISTER and his disciples should make sweeping statements respecting the general merits of their plan of treatment. To convince the profession as a body they must descend to particulars, and show by means of statistics what their average results are. Unless this be done, and the benefits of the system demonstrated in a manner altogether beyond dispute, it is useless to expect that medical practitioners, whether attached to hospitals or engaged in private practice, will discard the older and simpler modes of dressing wounds in order to adopt a plan that is extremely complicated, expensive, irksome, and laborious.

On the other hand, in estimating the value of a particular mode of practice, we should not be too exacting and reject all evidence that is not absolutely unequivocal. The general impressions of men who have had large opportunities for observation are worth something, and there are surgeons of eminence who have alleged that by means of Mr. LISTER's method they have obtained much better and more uniform results than they secured before they adopted it. Those who recently witnessed the demonstrations of Mr. LISTER and some of his colleagues could not have failed to be struck by the large number of serious cases that were doing well; but there were cases in the same wards that were doing as badly under the antiseptic treatment as they could be expected to do under any other plan of treatment. On the whole it may be doubted whether the average condition of the cases in the Edinburgh Infirmary at the time to which we refer was better than that of similar cases in many of the metropolitan hospitals. Oddly enough, there is at least one metropolitan hospital where one surgeon follows strictly and exclusively Mr. LISTER's plan and the other surgeons as persistently reject it. Here, one would think, there is some ground on which to stand and view impartially the merits of the two modes of practice. What is the result? After the experience of several years, not to put too fine a point on the matter, it is found that the success of the antiseptic system is certainly not greater than that of the ordinary methods, and it is stated to be actually less.

It is worthy of remark that the results obtained under the antiseptic system have progressively improved with every advance made in the mode of carrying out the details of the practice. The more thoroughly wounds are protected from the actual contact of carbolic acid, the more rapidly do they heal; and when we reflect on the serious imperfections of the early dressings compared with the minute refinements of the later methods, it is difficult to imagine how the results of that time could have been compared with those obtained by the ordinary means. Yet even those early attempts at antiseptic dressings were lauded as triumphs of modern surgery.

There is, however, another important department of practical surgery in which the antiseptic system is said to exercise a considerable influence. Mr. LISTER and his disciples allege that by regularly carrying out the principles of antiseptic surgery, pyæmia, erysipelas, and all the evils of hospitalism may be reduced to a minimum, if not altogether prevented. Testimony in confirmation of this statement has not been wanting either in this country or on the Continent. But even here the opinion of surgeons is not unanimous. THIERSCH, who is an ardent advocate of antiseptic surgery, has stated that, according to his experience, the frequency of erysipelas is not diminished by the employment of carbolic-acid dressings, and the same observer has now almost entirely discarded carbolic acid for the new antiseptic, salicylic acid, recently discovered by Professor KOLBE.

Until Mr. LISTER and his disciples can prove that the results of the antiseptic system are sufficient to compensate for the extra expenditure of money, time, and labour, it is certain that the minute details of antiseptic surgery will only be practised by enthusiasts who have time enough to devote to them. Whereas, if it can be demonstrated that the antiseptic system is immeasurably superior to the other modes of treatment, it will be the bounden duty of every conscientious medical practitioner to give it at least a fair trial. At a future time we shall consider some of the more recent developments of antiseptic surgery.

◆

THE examination in the University of Cambridge last week, in so much of State Medicine as is comprised in the functions of officers of health, leads us to consider the degree of recognition which has been accorded to the great branch of Medicine which contemplates the prevention and obviation of disease rather than its cure. The University of Cambridge is entitled to much praise for the earnestness and liberality with which it has instituted this examination. Other universities have made arrangements for granting qualifications in State Medicine. But the arrangements are conceived in a less liberal and practical spirit than is displayed by the University of Cambridge. The University of Edinburgh has established a science degree in the Department of Public Health; but the candidates for it must be graduates in Medicine of a British university, or of such foreign or colonial universities as may be recognised by the University Court. Candidates who have not passed an *annus medicus* in the University of Edinburgh must, before presenting themselves for examination, have attended as matriculated students in the University at least two courses of instruction bearing on the subjects of examination. The University of Dublin has instituted a qualification in State Medicine; but candidates must be graduates of one of three favoured Universities—to wit, Dublin, Oxford, or Cambridge. The Universities of Oxford and Cambridge only give their certificates in Sanitary Medicine to their own graduates. In a larger and more liberal spirit than these excluding conditions imply, the Cambridge University has established an examination to which all registered medical men who have attained the age of twenty-four are admissible. It is gratifying to find that such liberal conditions seem to be appreciated, and that no less than twenty-eight candidates responded to the offer of the University; of these, twenty-six actually presented themselves for examination, of whom eighteen held degrees from British universities, and eleven were medical officers of health. The candidates came from various parts of the empire, including Scotland, Jersey, and the principal provincial towns. At least two were connected with the Medical Department of the Army. When we add that this number included several practitioners of acknowledged standing, of whom we may mention Dr. CARPENTER, of Croydon, we have said enough to show that the University is supplying a real want. The questions put to the candidates at this examination are before us, and seem to us to be thoroughly searching and practical. They contemplate fitness strictly for the duties of medical officers of health. They do not include such subjects as forensic medicine and the analysis of food, &c. Perhaps they do not embrace so much of the principles of physics and chemistry as the candidates were led to expect, but they cover the whole field of practical hygiene. Not the least valuable part of the ordeal to which candidates were subjected consisted in their being sent as Health Inspectors to different parts of the town entirely unknown to them, with instructions to make a Sanitary Report on them.

Speaking of the recognition of sanitary medicine, it occurs to us that there is one body which has not done what it might have been expected to do. We mean the Royal College of Physicians of London. Last year it got great and deserved honour for bringing under the notice of the Government, which may be said to have come in on sanitary principles, the lamentable condition of the houses of the poor, combining everything likely to depress and injure the health of the inmates. Nevertheless, in its recognition of sanitary medicine it has been rather backward. It has among its Fellows men of the highest rank in this branch of medical work—such as Dr. PARKES, Dr. GEO. BUCHANAN, and Dr. BALLARD,—to whom it might well entrust the duty of speaking in the name of the College. Year after year passes by, and the duty of delivering the stated courses of lectures in the College is assigned to various Fellows. But hitherto the Fellows who devote themselves to sanitary medicine have been overlooked. Probably this has been quite undesigned on the part of the College authorities. We submit that they could not do better in appointing lecturers than to select one or other of their Fellows who would speak with authority on the subject of State Medicine. Such an appointment would be as beneficial to the public as it would be creditable to the College. There is still a lamentable jealousy of medical men in State departments, notwithstanding the constant demonstration of the evils which accrue to communities from neglect of the simplest truths in sanitary science. The very Acts of Parliament passed in stinted admission of those truths are rendered comparatively useless by the reluctant way in which medical advice is taken as to their application. Meanwhile epidemics stalk unchecked through the land. Last week over a hundred deaths occurred in London from scarlatina. Under such circumstances, the College of Physicians should give its most honoured chair to one of those Fellows who could speak to the profession and the public authoritatively on the preventable causes of disease. Such a course may fairly be expected from a body which claims to represent British medicine, and it cannot be long deferred without suggesting the criticism that the College does not fully realise the drift and scope of modern medicine. The Apothecaries' Society, in this respect, is in advance of the more pretentious institution in Pall Mall. It invited a distinguished sanitarian to discourse on *State Medicine* within its walls. Let us hope that the College of Physicians will lose no time in doing likewise.

◆

THE Address delivered by Dr. RICHARDSON, as President of the Health Section of the Social Science Congress, on Monday last, is remarkable for the felicity with which he discourses on a trite but vital topic. With a view to epitomise and illustrate the main features of a sanitary ideal, the lecturer conceived and described an imaginary city so constructed and controlled as to secure the conditions most favourable to a low death-rate, an almost complete immunity from disease, and a state of social happiness approaching the highest degree of perfection compatible with the natural laws of human life. The treatment of this time- and word-worn theme was startling and suggestive. A population, numbering 100,000, was distributed in 20,000 houses over 4000 acres. Three wide main streets ran east and west. Beneath each was a subway, with railroad for heavy traffic. The cross and minor streets were wide and the houses low, so as to secure sunlight and general ventilation. Trees and shrubs were judiciously planted at the sides of the public ways. Gardens filled the interspaces between the backs of houses. Public buildings of all descriptions were isolated and surrounded by ornamental grounds. The streets were paved with wood set in asphalte—noiseless, cleanly, durable. No tramways were permitted, the underground railways sufficing for the traffic. The pavements were everywhere ten feet wide, and of white or light-grey stone; slightly inclined to the roadway, which was so inclined as to drain towards the margins of the pavements, but there were no "gutters." The surface was easily cleansed by washing the dirt into the subways, through side openings under the footpaths; and the model city had neither cellars nor kitchens underground. The houses were built of glazed bricks, so that no absorption of water took place, and ventilation was secured by transverse perforations. Fresh air, admitted at pleasure through openings in the outer walls, circulated freely through the tubular brickwork, being heated, when necessary, by passing around the fireplaces. Mouldy and poisonous wall-papers were entirely obviated by the decorative effect of the glazed bricks, coloured and arranged internally according to taste. The ceilings were turned with light arches of thin brickwork; the chimneys collected in central shafts, connected with a gas furnace to destroy the free carbon. The roofs, only very slightly arched, were covered with asphalte or flat tiles, protected with iron palisades and turned into flower gardens. The kitchens and offices were immediately under the roofs. On the second or middle storey of every house was a bath-room, properly provided. The bedrooms were the objects of special care—well lighted, spacious, and thoroughly ventilated, 1200 cubic feet of air being allowed for each sleeper, and all "unnecessary articles of furniture and of dress rigorously excluded; old clothes, old shoes, and other offensive articles of the same order never being permitted to have residence there." The houses were warmed by special air-chambers, behind the open fires—which were retained for the appearance of comfort. The sewers of houses ran along the floors of the subways, and were built of brick. They emptied into cross main sewers, and were trapped for each house. The waterclosets were situated in the middle and basement floors. A continuous water-supply rendered flushing easy and safe—that is, safe as regards the danger of poisoning the drinking-water. There were no public-houses in Dr. RICHARDSON's ideal city, the use of strong drink being unknown. The people had become total abstainers, and they did not smoke. "Pipe and glass," says the lecturer, "cigar and sherry-cobbler, like the Siamese twins, who could only live connected, have both died in our model city. Tobacco, by far the most innocent partner of the firm, lived, as it perhaps deserved to do, a little the longest; but it passed away, and the tobacconist's counter, like the dram counter, has disappeared." The habits generally of the resident population befit the commodious city in which they are so beneficently located. They carry on their industrial pursuits with cleanliness, and without noise or nuisance. The factories are either outside the town or perfectly innocuous. The slaughter-houses are a quarter of a mile from the city, and under minute supervision. The Jewish system of inspection has been adopted, with the improvement that the inspector is a man of science. Nor are the sufferings of the animals slaughtered disregarded; they are, in fact, entirely obviated. The victim is passed through a narcotic chamber, and becomes oblivious of his fate. The slaughter-houses are drained into the sewers, and purity and cleanliness rigorously enforced. Of course the water-supply is absolutely pure and filtered for drinking purposes. The dead are interred in a cemetery designed and conducted on scientific principles, with a view to ensure rapid decomposition.

The sanitary results likely to be achieved, by the application of science to the preservation of health and the removal of every preventable cause of disease, Dr. RICHARDSON conceives to be the extinction of infantile diseases, such as fevers, convulsions, diarrhœa, croup, marasmus, and dysentery. Typhus and typhoid fevers and cholera would be only accidental interlopers, instantly excluded; small-pox would be under control; diseases of low specific type would be unknown; those which commonly arise from cold and damp would be practically interdicted; deaths from privation and the evil consequences of drink would cease; parasitic maladies would be extinct; and, in a word, the larger and nearly all the *produced* maladies to which gregarious human nature is exposed would be eliminated from the catalogue of social sorrows. A mortality of only 8 per 1000 would be the highest in the first generation living under these sanitary conditions and a scientific *régime.* In this picture of the imagination Dr. RICHARDSON has blended together the principal reforms which experience has shown to be desirable, and added some of his own devising. The disuse of stimulants and tobacco, with which the dwellers in Hygeiopolis are credited, is a crotchet it would have been better to leave out of the calculation. It is not yet regarded as an indispensable factor in the sum of health, and its introduction rather weakens than intensifies the force of the lesson it is desired to teach. It is only fair to Dr. RICHARDSON to notice that he does not, as many of our contemporaries suppose, give to "abstinence" the importance of an integral part of his scheme. He simply states the fact, and expressly guards the supposition that it was enforced. We repeat, it would have been judicious to omit it altogether. There are also defects of detail in the sketch, doubtless due to the necessity of touching the main points only, and even those lightly. For example, the lecturer does not explain how the dirt of the streets is to be "washed away every day through side openings into the subways and *conveyed with the sewage* to a destination apart from the city," without incurring the danger of a frequent or continual escape of poisonous gases from the sewers. The "side openings" suggested must surely allow vapours and effluvia to pass out of the sewers if they admit of the dirt being swept or washed in. The sewers are trapped towards the houses, but they cannot be trapped effectually in the streets if the dust of the roadways and pavements is introduced daily. Again, it is disconcerting to find that, while Dr. RICHARDSON is careful to place the slaughter-houses a quarter of a mile outside Hygeiopolis, he allows them to "drain into the sewers of the city." The needless introduction of putrefying animal matters into the sewers of a populated district would scarcely be a measure of hygiene! It was inevitable that many points of lesser moment should be overlooked in a sketch of the nature indicated. Nevertheless, we believe the ideal will serve a useful purpose. The conception may be Utopian, but, as Dr. RICHARDSON observes, Utopia is only another word for time, and it is well to have an object or standard of excellence towards which to work. The outline—so far as it deals with principles of construction; with provisions for the supply of pure water, good and wholesome food, pure gas, and an uncontaminated atmosphere; with measures and appliances for the care and isolation of the sick, for the protection of linen and clothes in public laundries and workshops let out on hire, for the avoidance of nuisances, for the relief of distress without pauperising the poor or removing them from the class of bread-winners, and for the cure of some of the worst evils incident to life in crowded cities,—is a contribution of great value to the cause of sanitary reform. It gathers into focus the scattered rays of light which have from time to time been cast on a subject of vital and daily growing interest; and the eloquent address of which it forms the summary is one which eminently deserves the thoughtful perusal of all classes, and of none more earnestly than the profession whose highest glory consists in showing the world how to prevent—while itself labouring for the cure of—disease.

◆

OUR weekly contemporaries have something to say on the recent "Introductories." The *Saturday Review,* in a thoughtful article, indited in a spirit of fairness, discusses the general condition of medical education, and the opening addresses, with frankness and moderation. The conclusion reached is, on the whole, favourable to the prestige of the profession and its teachers, and satisfactory as regards the status of pupils, the opportunities of study and usefulness they enjoy, and their social and general prospects. The *Examiner* is neither so cordial nor so complimentary. It takes up the position of a candid friend, and, in the most friendly fashion possible, it contrives to offer some of the least agreeable remarks and criticisms we remember to have fallen from friend or foe. It confesses that "the professional tone of medical men has distinctly risen in our own time, and by dint of more stringent supervision the doors of the profession have been closed upon ignorance and quackery." Even more significant is the admission that "no professional credentials are more trustworthy than those of the young doctor. By the fact of his qualifications we can be more certainly assured of his possessing a minimum of capacity and knowledge than we can be in the case either of a clergyman or a lawyer." After so consolatory an observation, it is at once surprising and disheartening to be told that, whereas "nothing can be more meagre than the professional training of a clergyman or a lawyer, yet, regarded as a liberal profession, Medicine is notoriously inferior to the Church and the Bar." There is a weak point in our contemporary's argument, for he acknowledges that Medicine "has as its basis the whole region of physical science, with its magnificent discoveries and its inspiring methods." The sum of the matter is simply this: the profession is liberal; it has within it "the elements of a liberal education," but, confessedly, the indispensable need of preliminary education has not in times past been adequately recognised or enforced. We scarcely think the education of medical men is inferior to that of members of the clerical or legal professions. But we have no wish to seek excuse for our own shortcomings in the faults and failures of other professions with which the medical may be arbitrarily compared. We believe there has been an unnatural estrangement of Medicine from the older universities. As the *Examiner* puts it, "the old universities have grievously neglected their duty towards an important profession." Thus far we are with our censor; but he goes a length wholly unwarranted when he asserts that "the London medical system" is "a mistake." The system adopted at our medical schools may not be perfect. It would doubtless be better if it were more collegiate, and if the discipline and social training of a resident university could be combined with the special advantages of a technical school. But the concluding sentence of the *Examiner's* article is the bitterest of all: "Probably no profession or trade in the world makes so little use of its best opportunities." We are prepared to accept any reasonable amount of censure in a spirit of meekness and teachability; but this parting shot is a little wild. It is true we may be too much engaged with the practical aspect of our profsesion. The general tone of recent addresses, unfortunately, gives some colour to this remark; but Medicine has been lately engaged in a struggle for social and a political recognition which is not yet secured. When the absorbing questions raised by the creation of a system of State Medicine are settled, if anything more can be done to raise the status of the student seeking admission to the scientific profession of medicine, consistently with a due regard to the exigencies of the technical pursuit—such special requirements as are found to limit the choice of recruits for the scientific corps in all services,—our lay contemporaries may rest assured no pains will be spared to attain that object; for the end to be gained is not less dear to the profession than to its critics, friendly or supercilious.

Annotations.

"Ne quid nimis."

THE ROYAL COLLEGE OF SURGEONS.

AT a special meeting of the Council of the Royal College of Surgeons, held on Wednesday last, Mr. Erichsen was elected a member of the Court of Examiners in the vacancy occasioned by the resignation of Mr. Henry Hancock, and Mr. Le Gros Clark and Mr. Savory were re-elected to the Court. This election, as we pointed out last week, is a triumph in several respects. It shows that the College has at last been roused to participate to some extent in the spirit and enterprise of the times. In the general satisfaction that will be felt at Mr. Erichsen's election to the Board of Examiners, it must not be forgotten that this election involves a principle of the first importance to the profession. Mr. Erichsen has accepted an examinership on the distinct understanding that the examiners in surgery and surgical pathology will henceforth be distinct and separate from those in anatomy and physiology. It may therefore be confidently expected that the alteration will at once be made. The arrangement has, we believe, already met with the approval of most of the examiners, some of whom will be heartily glad to be freed from the responsibility of examining in anatomy and surgery. It is for this that we have so long contended.

STRYCHNIA AS A "PICK-ME-UP."

BEFORE the Norwood case drops out of memory, it may be desirable to point the moral of the dismal tragedy. The use of strychnia (the active principle of nux vomica) as a restorative is, it is to be feared, by no means uncommon. It probably forms an ingredient in many of the mischievous compounds known as "pick-me-ups," and is taken and administered by unprofessional persons with a recklessness perfectly astonishing when it is remembered that the drug is one of the most potent and dangerous poisons in use as medicine. Harm has been done by the lay-reading of such passages as the following, which we quote from Pereira's "Materia Medica," a book, like all valuable works of its class, intended for the use of medical readers exclusively, but which, falling into unskilled hands, and being consulted, as many weak-minded persons consult a "Domestic Medicine"—much as they repair to a cookery-book,—may be infinitely harmful and perilous:—"I have seen nux vomica very serviceable in shaking or tremor of the muscles produced by habitual intoxication. A gentleman thus affected, who had for several weeks lost the power of writing, reacquired it under the use of this medicine." Acting upon a statement of this kind, chemists and laymen have dared to play with the drug, and the consequence has been a perpetual risk of misadventure like that which recently occurred at Norwood. There is not the slightest reason to suppose the poor inebriated fool who poisoned a woman the other day cherished a thought of committing murder. He simply played with a weapon he had not the power to use, and being more than commonly foolish on a particular occasion, poisoned the person he meant to cure. The lesson to be learnt from the incident is that the use of drugs by people not acquainted, first with their nature and properties, and then with the nature and functions of the organism it is designed to treat, is *always* perilous. The practice of handing about prescriptions and recommending medicines which have been found serviceable in a particular case to other persons *supposed* to be suffering from the same malady, but to whom the "valuable remedy" may prove so much poison, is fraught with extreme danger, and ought to be deprecated quite as strongly and generally as the not more childish practice of playing with fire. If the moral of the "Norwood mystery" is understood and appreciated, a calamitous episode may serve to illustrate, and perhaps put a stop to, a pernicious and reckless custom, which has often been denounced, but unhappily in vain.

ENCOURAGEMENT TO PUPILS.

THE art of administering encouragement, and offering a suitable incentive, to young gentlemen commencing the study of medicine, is not, it would seem, generally understood. Mr. Richard Davy, of Westminster Hospital, may claim to be the originator of a new system. It will require time to show how far the method is successful, but there can be no question as to its novel character, and unlikeness to the modes employed elsewhere. Mr. Davy cannot be accused of obtruding his discovery on public attention; on the contrary, he produced it under protest. The occasion was the delivery of an "Introductory" on the 1st inst., and Mr. Davy "disapproves *in toto* of introductory addresses." He conformed to the custom at the request of the Medical Committee of the school he adorns, but was quite sure "students and teachers would infinitely prefer one day's pheasant-shooting to hearing or giving an introductory." Looking to the sequel we cannot but commend the preference. "As a surgeon," Mr. Davy was considerate enough to promise he would "cut down this sermon from one hour to fifteen minutes," and he expressed a belief that his successor "might still further reduce the volume of these fruitless harangues." Mr. Davy is too modest. We should not be surprised to hear that his recent address at Westminster had borne fruit of a kind which the astute lecturer would much appreciate, and led to the abandonment of introductories at Westminster "*in toto.*" The general views entertained by Mr. Davy on the subject of medical education are interesting and remarkable. He does not attach much importance to "elaborate teaching." A "self-reliant young man," Mr. Davy thinks, will find "his own efforts suffice to pull him through." "University residence and discipline" are, in Mr. Davy's opinion, to be "strongly insisted on," because the training implied begets "a healthy tone and life-long friendships," and young men are saved from making the acquaintance of "some interestingly repulsive specimens of shark (*squalidæ*), known as London landladies." On these high grounds, Mr. Davy concludes that if he had to "repass" his time he would "commence a course of study by graduating as a Master of Arts at Oxford or Cambridge." He is convinced that "it is by no means waste of time so to do, and much inconvenience of preliminary examinations is got over." Mr. Davy is quite right. If every student of medicine would only commence his studies by becoming a Master of Arts, he would escape preliminary examinations; and if he got himself dubbed "Doctor of Medicine" before he began, he would find professional examinations also "got over," and generally avoid a world of "inconvenience." But why take this trouble to enter a profession which offers only the allurements Mr. Davy is able to hold out? "Hospital physicians and surgeons," says Mr. Davy, "are for the most part unpaid." This is really very extraordinary, considering that nearly all the appointments are purely honorary. Medical officers under the Poor Law and in the services are treated worse than they are paid, "and young practitioners are not paid at all." Probably this last circumstance may be explained upon the same hypothesis that accounts for the predicament in which young and briefless barristers are apt to find themselves. Mr. Davy personally has been fortunate. "For seven years' hard work at the St. Marylebone Dispensary" he "received one guinea." We regret that the lecturer did not explain how he became possessed of the coin in question. Was it for honorary work, or does it represent the balance of his receipts over his expenditure? Mr. Davy also, it seems, knows "a very distinguished London assistant-physician" whose "salary (!) equalled that earned by the man who put the skid on the 'bus wheels at Holborn-hill." Holborn-hill is not now extant, and we do not remember to have heard the salary of the man who put the skid on 'bus wheels there when the hill was still in existence. Nor have we any idea how much a very distinguished London assistant-physician usually receives as *salary*. It is too bad of Mr. Davy to excite curiosity on so many points and leave it unsatisfied. The picture Mr. Davy paints of his profession generally is so lugubrious that perhaps we ought not to be surprised at the terms in which his lecture closes. "In conclusion, let me firmly assure you that your prospects in life are most disheartening. Your toil and ambition may be equally great, but your pay and dignity will be equally small. You have to deal with an ignorant and proud people." The moral Mr. Davy deduces from this deplorable state of things is, that a young gentleman intending to enter the profession ought "to resign at once any and every thought of becoming a medical man unless he possessed three qualifications. First, independence; second, an aptitude for, and love of, the profession; third, the readiness to pay a heavy premium in this world for his prospects of reward in the next." The application of the insurance principle to the encouragement of young medical students is a stroke of genius in which the efforts of Mr. Richard Davy happily culminate. If the students at Westminster were not encouraged by this stirring address, possibly it will be wise not to repeat the effort for their improvement when the opportunity next comes round. We are of opinion that introductories may be made useful, but we doubt whether the course pursued at Westminster is the most promising.

MEDICAL OFFICERS OF HEALTH AND INFECTIOUS DISEASES.

At the close of a somewhat discursive discussion, following the reading of a paper in the Health Section at the recent Social Science Congress, a resolution was passed recommending that the Council of the Association should consider the desirability of securing by legislative enactment that all cases of infectious diseases should be reported to the local medical officer of health. This resolution simply calls attention to what is now felt by medical officers of health to be one of the principal drawbacks to their usefulness. Until they receive early intimation of all cases of infectious diseases, they certainly are in a great measure powerless to control the mortality from epidemics. The question, however, which has to be solved is, who is to be bound by legislative enactment to report these cases to the medical officer of health? The resolution above mentioned in its original form recommended that medical men attending cases of infectious disease should be made responsible for reporting them to the medical officer of health, but this proposition was strongly opposed and was subsequently withdrawn, on the ground that it would be unfair to the medical profession, at the same time that it would not secure the reporting of those numerous cases which are not attended by any medical man. In cases of infectious diseases among cattle, the owners are bound under penalty to report the fact to the police, and it certainly seems anomalous that precautions pronounced by Parliament to be necessary for the safety of our cattle are not enjoined for the protection of human life. It appears to us that the occupiers of a house in which a case of infectious disease occurs, and relatives residing with the patient, might fairly be made responsible for transmitting this important and necessary information to the local medical officer of health.

THE PRINCE OF WALES'S TOUR IN INDIA.

The Prince of Wales has started for his Indian tour, bearing away with him the best wishes of everyone in this country. Apart from sentiments of loyalty, which undoubtedly permeate all classes, and the political and social interests connected with one in his exalted position, the Prince of Wales exhibits many qualities and tastes which make him popular with Englishmen, because they share them. They can sympathise with his keen enjoyment of sport, his appreciation of the pleasures of change and travel, and they recognise a sense of spirit and broadmindedness in his desire to visit the vast and distant territories united together under British rule. It is natural that there should be a certain amount of solicitude as to the Prince's safety, and it is equally natural that a certain number of gloomy people should shake their heads, because gloomy persons are to be found everywhere, and they would have no *raison d'être* if they failed to perceive some cloud or other in every prospect. It is said, however, that life assurance offices do not altogether like the Prince of Wales's expedition to India. For our parts, we fail to perceive any adequate grounds for believing that the Prince will incur, as far as his health is concerned, any greater risks in visiting India than in remaining at home. The climate of India at the time the Prince will visit that country is as healthy as, if not healthier than, England, and we may be quite certain that those of his suite who are possessed of an intimate knowledge of that country and its diseases will neglect no precaution in guarding his health and in so shaping his journey as to avoid exposure to malarious localities and other places where any sources of danger may be apprehended. Dr. Fayrer, for example, in addition to the knowledge which he has derived from a long residence in India and an intimate practical acquaintance with the diseases incidental to a tropical climate, will unquestionably have at his command all the latest and most reliable information as to the sanitary condition of every portion of country included in the Prince's proposed route. We trust that neither matters of policy nor pleasure will tempt the Prince to prolong his visit, however, beyond what is considered the healthy season, but that his departure will be timed so as to avoid the risk and discomfort of the Red Sea in the homeward voyage.

Meanwhile, his Royal Highness was more fortunate in the weather he experienced in crossing the English Channel than those of his suite who preceded him on Saturday, for they had every opportunity of practically testing the effect and relative value of the alleged factors in causing sea-sickness. Whether the lateral rolling or the up-and-down pitching movement, in which the abdominal viscera fail to accommodate their position to the precipitate descent of the rest of the body with the pitching of the ship, or whether the combination of all these movements, be most efficacious in causing sea-sickness, they should now be able to determine, if any of those who happened to suffer in this respect had mental power enough left under the circumstances—which we much doubt—to analyse their sensations.

MEDICINE IN THE "DAILY TELEGRAPH."

PUBLIC OPINION on medical subjects is always largely influenced by the lay press, which often fulfils a useful office in interpreting to the outside world the steps which mark to us the advance of our sciences. But it is important that no over-hasty generalisation, fraught it may be with uncalculated danger, receives the stamp of current circulation by its adoption in columns which are regarded by their readers as an unimpeachable authority, and great care should be taken to encourage as far as possible a wiser tone of thought on many subjects than at present prevails. We regret to have observed some neglect of these precautions in the leading columns of one of our daily contemporaries. The tone of two recent articles on medical subjects in the *Telegraph* has been to encourage some serious errors. A notice not long ago, accepting as unquestionable the alleged success of the hypophosphites in the treatment of phthisis, placed a remedy of most doubtful value before the public in a very misleading manner, and encouraged, by its tone and statements, that demand for specific remedies which at the present day finds little encouragement in scientific facts. A similar encouragement to popular error is to be found in a still more recent article on the subject of anæsthetics, in which the writer, in the *Telegraph's* most florid style, calls for the discovery of a "perfect anodyne which, without peril or after evils, would give us absolute control of this Devil of pain." On the moral significance of the expression we do not comment, but would remark that neither past experience nor present analogy gives us any reason to suppose that any anæsthetic will be discovered the use of which will be devoid of risk. No known facts suggest the probability that we shall ever be able to throw at will the nervous system into such a condition as to be insensible to the strong stimulus to which it is naturally so keenly sensitive, except by exposure to influences which will entail danger of permanent injury. Neither by anodyne nor anæsthetic can suffering be abolished with perfect impunity, and, in proportion to the interference with nervous function is, and always will be, the risk of immediate or ultimate damage. Our contemporary would have done more wisely in pointing out this clear teaching than in encouraging hopes which past experience and present knowledge alike forbid.

THE MODERN PHYSIOLOGICAL SCHOOL.

DURING the late Medical Congress of Brussels, M. Marey gave a conference at a clubhouse, kindly accorded for the occasion, for the purpose of exhibiting the various mechanical contrivances with which he gives mathematical precision to physiological research. The Professor will certainly be instrumental in reviving, with improved machinery, the ancient school of iatro-mathematicians. As regards this revival, M. Marey observed that, until within a recent period, every investigator built up a physiology of his own, arbitrarily assigning certain functions to individual organs. Now, however, modern physiologists chiefly rely upon the aid afforded by exact methods and accurate apparatus borrowed from physics and mechanics.

The audience were much struck and interested by the experiments brought before them illustrating chronography—viz., the measurement of motion through time and space. The apparatus, which we cannot describe here (see *l'Union Méd.*, Oct. 9th, 1875), is self-registering. Then came ingeniously constructed myographs, pneumographs, and cardiographs. An instrument by which the rapidity of the circulation of the blood can be accurately determined was subsequently shown, as well as one intended to register temperatures. If medical men will add to this some method of accurately curing disease, there will hardly be anything left to invent. As to the ear, an important aid has just been proposed by Dr. Weber Liel. This physician showed, at the Congress of Gräz, a very cleverly contrived ear microscope, which, with the ordinary sunlight, not only shows the membrana tympani enlarged fifteen diameters, but the normal and pathological movements of its different sections. These latter phenomena are made manifest by connecting the membrane with an india-rubber tube and a box, in which organ-pipes have been adapted. The sounds of the latter will indicate the force of the movements. Advantage is also taken of the reflected light afforded by starch dropped on the membrane.

FUNERAL REFORM.

THERE is one very remarkable custom in this country which remains unaffected by the changes of time. It is our funerals. Connected with these there is a thriving class who manage to survive all attacks on their order—undertakers. So imperious and tyrannical is fashion that few people have the strength of mind and character to deviate one hair's breadth from the usual course in the matter of a funeral. There is no need to warn undertakers of the danger attaching to a condition "when all men shall speak well of you," for they are a long way from having attained that perilous position. Still, if people abuse, they are all compelled to use them. Poets, satirists, and novelists have depicted "the mockery of woe" of our modern funerals, and laid bare its cruel shams; but, somehow or other, the world is content to go on with practices which are revolting to common sense and opposed to Christian sentiment. There are a good many sensible people in the world who would gladly welcome the cremation, the "earth to earth," or any other system which would rid society of the very ugly, dismal, and expensive mockeries connected with funerals as they are conducted in this country. At the late Church Congress in the Potteries several influential members of the clergy and others discussed this subject of "funeral reform," and it is certainly time that something was practically done by way of abolishing a host of things which are a grievous burden to needy but respectable people, and a source of worry and annoyance to all. The reform must proceed from above downwards—from the upper, aristocratic, and educated classes, before it can reach the lower and less educated. To say nothing of the present system of funerals being opposed to the spirit of Christianity, and utterly unworthy of people professing to be sincere believers in its tenets, much of it is unmeaning. As the Rev. Dr. Collis urged, would any man of common sense explain what "was the use of mutes, except that in funerals, as in grammar, they invariably suggested the accompaniment of liquids. What was the use of pages, except that they suggested pages of the ledger which they would have to pay for? Why should the horses be made such guys of? What did particular plumes mean? Why were certain of these carried by a page on a triangular tray? Would anyone say why these funerals were so dismal?" The present ugly custom extends from the house to the grave, and back again. Scarves, streamers, weepers, hatbands and gloves, mutes and mourning coaches, are the concomitants of a funeral in the present day; and sometimes these are provided from a feeling of ostentation, sometimes out of a sense of respect and affectionate regard for the dead, and in order that the deceased shall have a funeral equivalent to his rank or position in society; and, very generally, because the survivors at such a time have not the strength of mind or moral courage to withstand the dictatorial suggestions of the undertaker. Medical men and clergymen have the opportunity of estimating the effects of all this in many instances in impoverishing the family at the very time, perhaps, when there is most need for economy. Then the practice of supplying refreshments at the house from which the funeral starts is, in the case of the upper classes, an unnecessary and unfeeling infliction on the household, and in the case of the lower it is sometimes even demoralising in its tendency. Who has not seen, too, the returning hearse pulled up before a public-house, whilst the men in sombre garments were refreshing the inner man? It is not unnatural, of course, but it is an unpleasant sight. What is wanted is that all who view these matters as we do should set the example of having funerals conducted with the utmost economy and simplicity consistent with decency.

ADDITIONAL REMUNERATION TO REGISTRARS OF BIRTHS AND DEATHS.

UNDER Section 31 of the Births and Deaths Registration Act, 1874, an additional remuneration was granted to registrars of births and deaths, which it is estimated will cost the country about £10,000 a year, and be equivalent to an annual gratuity of £4 10*s.* to each of the 2194 registrars who make as many as eighty entries of births and deaths during a year. There are, however, a considerable number of registrars in thinly populated parts of the country, whose districts, although of very large area, yield far less than eighty entries in a year. Section 29 of the original and principal Registration Act (6 and 7 William IV.) sanctioned the payment by the guardians out of the rates to the registrars of two shillings and sixpence for each of the entries of births and deaths made in every year; the remaining entries being paid for at the rate of one shilling an entry. By the recent Registration Act every registrar is entitled to half-a-crown for the first twenty entries made in each quarter, instead of for only the first twenty in each year. This, as we have stated, is in the majority of cases equal to a gratuity of £4 10*s.* per annum. In order, however, that this additional remuneration should not form a further charge upon the local rates, it is provided that the amount paid by the guardians to the registrars on this account may be repaid to them annually out of a Parliamentary grant for the purpose. This repayment will only, however, relate to three quarters of the year, as the extra payment for the first twenty entries in the first quarter of each year was by the original Act defrayed out of the rates.

SURFACE DRAINAGE.

THE medical officer of health at Beverley (Dr. Stephenson), in his latest report, draws attention prominently to a matter of widespread interest. Considerable portions of a district under his inspection he found "depending only on surface drainages, and, owing to the town system of drainage being insufficient, they cannot easily have their condition improved." The common results of this defect in a district are apparent when the rainfall becomes excessive: the drains overflow, and the water comes back into the houses, carrying with it the impurities lying on the surface and much of the foul matter which has entered the drain. Before the main-drainage system of the metropolis was commenced—in the old days when the Fleet Ditch, covered in and converted into a temporary sewer, did duty as a general waste conduit, it was calculated that regurgitation from the sewers to the drains, and from the latter to the house-conveniences, always happened after twenty minutes' continuous rain. Unfortunately, surface-drainage still exists, as the only system of sanitation in too many districts. All appliances and schemes aimed to purify districts labouring under this radical defect must prove abortive. In short, it is no use patching up a system so defective. Summary reconstruction under the new powers provided by the Public Health Act is the only remedy.

OUTBREAK OF ENTERIC FEVER ON BOARD THE "CORNWALL" SCHOOL-SHIP.

WE learn that in addition to the twenty cases of fever admitted into the Seamen's Hospital last week, there are seventeen cases in the sick ward on board the *Cornwall.* This makes the number of boys attacked with fever thirty-seven, the total number on board being about two hundred. We understand that an inquiry into the causes which led to the outbreak will be undertaken by the Port Sanitary Authority. The strongest suspicion attaches itself to the drinking-water; and a rigid inquiry will no doubt be instituted as to the means that had been taken to prevent this from becoming polluted with any chance specifically contaminated excretory matters. This outbreak furnishes another illustration how careful ship-captains and ship-owners ought to be with respect to the character of the water shipped on board their vessels. No water ought to be shipped unless it is taken from a source sanctioned by the Port Sanitary Authority, and all supplies taken from the river or from river-side wells ought to be prohibited entirely. We are pleased to be able to state that all the cases in the present outbreak are now progressing favourably towards recovery.

THE HARVEIAN SOCIETY.

THIS Society, following the example of the Medical Society, has just instituted a course of lectures to be delivered annually. The first of the Harveian lecturers is Dr. Sibson, who has chosen for his subject one which, it will be remembered, he took up in the Lumleian Lectures at the College of Physicians two years ago—viz., "On Bright's Disease and its Treatment, considered mainly in relation with arterial tension from blood-contamination." The lectures are appointed for December 2nd and 16th.

NEW PRETEXT FOR DELAY.

WE regret to find Liverpool in the van of obstructives opposing or delaying the application of the Artisans' Dwellings Act. It is with even greater concern we find the local press shifting the blame to the shoulders of the local medical officer. They allege that Dr. Trench has recommended the corporation not to demolish some buildings he has declared fit only to be demolished, *until* they have ascertained "how far capital is likely to be placed at their disposal for building up where they have pulled down!" This is nothing more or less than creating a new pretext for delay. We take it that a medical officer has nothing whatever to do with the financial question. The question whether the Government will be able to lend funds for the schemes it sanctions is not in any sense medical. We cannot believe a medical officer has hesitated to discharge his obvious duty to the cause of public health lest he should inconvenience the local corporation or the Local Government Board, or, perhaps, even the Treasury. The aspect of affairs in Liverpool and the tone of the local press are, however, bewildering, and require explanation. The laborious inactivity of Liverpool contrasts most unfavourably with the energy displayed by the authorities of Birmingham, as detailed by our own correspondent in another column.

THE NEWCASTLE GUARDIANS AND THE VACCINATION LAWS.

IT is gratifying to notice that the Newcastle Board of Guardians, though instigated to talk nonsense about liberty by a communication from the guardians of the Keighley Union, refused to pass the following resolution by a majority of sixteen to nine:—"In cases where persons refuse to have their children vaccinated on conscientious grounds, and when the persons so refusing have already been fined for the same offence, this Board directs that no further action should be taken against such persons." The liberty to have small-pox, and thereby to convey small-pox to others, is a liberty that we are better without. The mortality caused by small-pox among unvaccinated children is 50 per cent. By vaccination it is reduced to less than 7 per cent. The people of Newcastle are, we hope, too sensible to show opposition to a law that has so immensely saved life.

HEALTH OF MILE-END.

IT must be conceded that the metropolitan medical officers of health are carrying out their responsible functions under the Sanitary Acts with great tact and ability. The official reports compiled by these gentlemen, which we receive from time to time, contain ample evidence of assiduity, and of a careful surveillance over the health of their respective districts. The report of the sanitary condition of Mile-end for the year ending March, 1875, has just been issued by Dr. M. Corner. Like many of his colleagues, Dr. Corner has been hampered in his work by the difficulty created last year regarding the supply of district registrars' returns. The deprivation of these returns has hindered him from collating such complete statistical information as he would desire to embody in a health report. We trust this matter, which has for some time been the *bête noire* of vestries and their medical officers, will now be definitely arranged. The Registrar-General evidently cannot recede from the position he has taken up with regard to the subject. We find that the hamlet of Mile-end maintains its reputation for salubrity. A high birth-rate and a low mortality prevailed during the past year. No special manifestation of zymotic disease occurred in the period. There appears to be some amount of overcrowding in the district, which will doubtless soon be remedied by the application of the Artisans' Dwellings Act. The Adulteration Act is working satisfactorily. Of the numerous samples of food &c. examined during the year by Dr. Corner, very few were found to be adulterated.

THE ACADEMY OF MEDICINE.

A GOOD example has been set and material assistance rendered to the progress of scientific medicine in France by the legacies recently left to the Académie de Médecine by MM. Desportes and Demarquay. The former has left 30,000 francs, the interest of which is to supply an annual prize for the best memoir on a therapeutical subject to be chosen by the Académie. M. Demarquay has left to the Académie the sum of 100,000 francs towards the erection of a building for its use worthy of the position the Académie has obtained. In case the cost of erection of such a building is defrayed by the Government, the interest of the legacy is to be devoted to the establishment of an annual prize, the subject of which is to be decided by the Académie. M. Demarquay has also left a legacy to the "Association Générale de Médecine de France."

THE Royal National Lifeboat Institution has already this year been instrumental by its lifeboats and other means in saving 574 lives from shipwreck on the British coasts. There is little flourish of trumpets in the way this noble institution performs its work. Men are rescued every week from untimely ends through its comprehensive machinery, while the public shows very little acknowledgment of its efforts—indeed, takes small interest in its existence. At a meeting held last week, under the presidency of Mr. Chapman, an account of recent proceedings of the Society was given, when it appeared that sums amounting in all to £5220 had been given to the various lifeboat establishments. We are sorry to observe that the receipts look very small in comparison with this sum.

BY the munificence of Miss Clugston, an estate named Broomhill, with its noble mansion, situated at Kirkintilloch, has been purchased for £14,000, and was opened last week as a Hospital for Incurables. A large number of distinguished visitors were present at the inauguration, and amongst them the Earl of Shaftesbury, who uttered some weighty words on the need of such institutions and on some of the points which require to be observed for their successful management. In a subsequent speech the earl referred in highly laudatory terms to the energetic and praiseworthy efforts of the sanitary authorities of Glasgow, which had resulted in so conspicuous an improvement of their town.

DR. WHITMORE, medical officer of health for Marylebone, in a report just issued, expresses an opinion that the time has now arrived when the serious attention of the Government should be given to the consideration of such further amendments in our present Sanitary Acts as will provide for the compulsory isolation of all persons suffering from infectious diseases. A legal enactment for the separation of infected patients would without doubt be instrumental in diminishing disease, but the difficulties in the application of such a law must not be underrated; we fear it would take a long time to accustom the public to its operation.

AT the Social Science Congress, Dr. Fussell, medical officer of health for East Sussex, read a paper in the Health Section on "the best means for rendering English watering-places more efficient for obviating the dangers arising from the occasional introduction of infectious diseases, and for determining the annual rate of mortality in such districts." Dr. Fussell insists that it should be made punishable to remove a patient within six weeks from the commencement of a contagious disorder without a certificate from the practitioner in attendance or from the sanitary officer.

A MEETING of the Pharmaceutical Society was held last week, under the presidency of Mr. Hills, on the occasion of the commencement of a new session in the educational department. Professors Bentley, Redwood, and Attfield testified to the great progress made during the past summer in the subjects of Chemistry, Materia Medica, and Botany—branches of study over which these gentlemen most ably preside. Mr. Ekin, of Bath, in the course of the evening, delivered an excellent address, in which the functions of pharmacists were very clearly defined.

AT the Poor-law Conference, held at Southport, a resolution has been passed to the effect, that inasmuch as provision is made in connexion with all modern workhouses for chronic and harmless lunatics, with the sanction of the Local Government Board and under the supervision of the Commissioners in Lunacy, the Government grant of 4s. a head now paid in respect of pauper lunatics in asylums ought to be extended to such unions.

Dr. Griffith, medical officer of health for Sheffield, has issued his second annual report of the sanitary condition of the borough. The report is compiled with evident care, and contains some interesting information, statistical and otherwise. Scarlatina was fatally prevalent in the town last year, 671 deaths being registered from this cause alone, and there is reason to fear a continued increase of the disease. The number of deaths returned as uncertified seems very large—572. Infantile mortality reached a high figure, 2045 infants having died under one year of age out of a total return of 10,857 births. Dr. Griffith deplores the need of mortuaries and of accommodation for patients with infectious diseases in the town.

In London, last week, 1397 deaths were registered, including 21 from measles, 110 from scarlet fever, 15 from diphtheria, 47 from whooping-cough, 29 from different forms of fever, and 105 from diarrhœa. No death from small-pox was registered. Different forms of violence caused 39 deaths in the period. A death from chloroform while the patient was undergoing operation occurred at the Seamen's Hospital. The Asylum District Fever and Small-pox Hospitals at Homerton and Stockwell contained 314 patients on the 9th inst., of which number one only was a case of small-pox.

At a meeting of the Metropolitan Asylums Board, held last Saturday, under the presidency of Dr. Brewer, the report of the Select Committee of the House of Commons on the Hampstead Hospital question was read. Afterwards it was agreed to appoint a special committee of the Board to consider upon the best means of utilising the suggestion of the report, to the effect that administrative blocks should be erected on the vacant lands in possession of the managers.

The Queen has granted to Dr. William Cormick, who is actually employed beyond Her Majesty's dominions, in the medical service of the Shah of Persia, in which he holds the appointment of chief medical officer attached to the heir apparent to the throne of Persia, her royal licence and authority that he may accept and wear the insignia of the Second Class of the Order of the Lion and Sun, conferred upon him by his Majesty.

We understand from the *Jewish World* that there is great dread of an outbreak of cholera in Jerusalem. Preventive measures are actively pushed forward by the authorities of the city, and the physician attached to the Rothschild Hospital is circulating a pamphlet in which advice and instructions are given to the inhabitants. They are particularly exhorted to practise the virtue of cleanliness.

A child has been poisoned at Barnsley by taking Harrop's Soothing Syrup, which, on analysis by Mr. Palmer, of the firm of Worley & Co., Market-street, Manchester, was found to contain morphia! When will Government compel the publication of the composition of quack medicines, and appoint some responsible person to forbid the sale of such as are dangerous to life?

NEW STUDENTS.

The following is the latest return of the number of fresh students at the metropolitan medical schools this session. The returns give all the new entries at the schools, whether first-year's students or not:—St. Bartholomew's, 120; Guy's, 98; University College, 85; St. Thomas's, 74; St. George's, 46; Middlesex, 41; St. Mary's, 38; London, 33; Charing-cross, 32; Westminster, 11.

REPORT
OF
The Lancet Commission
ON THE
SANITARY CONDITION OF OUR PUBLIC SCHOOLS.

SHREWSBURY.

The school at Shrewsbury was established in the reign of Edward the Sixth as a grammar school for the free education of the sons of the townsmen, the head master being permitted to receive boarders into his house who were to be maintained at their parents' charges. Shrewsbury, in spite of the comparative smallness of its numbers, has always held a prominent position among our chief public schools, and during the last forty years its career has been most brilliant. Shrewsbury men have repeatedly attained the distinction of Senior Classic at the University of Cambridge, and quite recently this honour has been obtained by them three years in succession; whilst since 1848 no less than twenty-one Porson Prizes at the same University have fallen to their share, and since 1868 they have carried off ten University (not College) scholarships. Such success is, we believe, unparalleled, and appears marvellous when we consider that the school rarely exceeds 170 in number, and that there are no entrance scholarships to attract boys of special promise to it.

The school buildings are situate in the town on a rising slope of ground overlooking the river on the west, and occupy about two acres and a half of ground. The school proper consists of a block of stone buildings, three storeys high, which contain the class-rooms, the library, and chapel. The houses belonging to the head and second master lay at right angles to the main buildings, forced back into a somewhat cramped position on the edge of the slope. At the entrance from the town is a small house containing studies. All the buildings are extremely old, and, with the exception of those having class-rooms, decidedly insufficient for the requirements of the school. In consequence of this cramped and crowded condition of the buildings containing the studies and dormitories, the governing body have determined to remove the institution to a more spacious and open site. It may be asked,—What use can any criticism of ours be now, as the school is to be removed? We reply, that the sanitary arrangements at Shrewsbury show what school authorities can do towards rendering their buildings healthy under the most disadvantageous circumstances; and a description of what has been done at Shrewsbury will serve as a useful example to those schools which still lag behind in matters of sanitary reform. It has been remarked that the health of the Shrewsbury students has been "inconsistently" good, considering the close and narrow quarters they have have had to live in; but this inconsistency is explained when an examination of the premises is made, and the care expended on minute sanitary details observed. Great credit is due to Dr. Kenedy (the late) and the Rev. Mr. Moss (the present head master), for their labours in this direction; and we also think that the school has benefited in having the advice and assistance of Sir James Paget, who is a member of the governing body.

The school at present numbers 175 boys, 115 of whom are boarders. The majority of the boarders reside with the head master in two houses, one house for juniors, the other for seniors; about 15 boys reside in the second master's house; all these buildings being on the school premises. Twenty-seven of the junior boys also board with the French master and one of the assistant masters at their private residences in the town. The remaining 33 boys live with their parents or friends in the town, going backwards and forwards to school once or twice a day. Our inquiry only extended to the houses occupied by the head and second masters actually situate on the school premises. The houses in question are, as we have said, extremely old, and look perhaps more dilapidated than they really are in consequence of the walls being nearly all panelled with wood, which successive generations of boys have hacked and hewed about. The staircases are narrow, the rooms small, and pushed as it were all together. Three-fourths of the boys have studies, about four boys to one room; they sleep in small dormitories, which contain from three to four beds as an average number. The rooms perhaps are not large enough in every case for the number of occupants, but every means has been adopted to secure efficient ventilation; and this has been more easily carried out than is usually the case, owing to the huge old-fashioned chimneys which abound throughout the building. In addition to the studies, the senior boys have two large common sitting-rooms, in which they usually prepare their work, though they are not limited to these or to the studies, for Mr. Moss has wisely permitted the boys to prepare their work in any part of the school premises, a privilege that the boys fully avail themselves of, and in this way the most is made of a very confined space. The class-rooms are situate in the main block of buildings, and are airy and light; if the seats were arranged across the room instead of with the backs to the windows it would be better, as by the present arrangement the shadow must be cast before the boy on to his book or paper at some time of the day; by the other arrangement the shadow would be thrown aside of him, either right or left, but clear of the book or paper. The hours at Shrewsbury are as follows:—Chapel at 7.45, breakfast at 9, school from 10 to 12, and on long-class days, Mondays, Wednesdays, and Fridays, from 3 to 5. Practically the long-class days are only two in number, one generally being taken as a holiday. We therefore get seventeen hours a week as the average work in school, to which must be added about twenty hours more as time expended in preparation of lessons. This gives six hours of work a day; the success of the Shrewsbury boys certainly cannot therefore be attributed to undue cramming or severe pressure put upon them. The junior boys go to bed at 9, the seniors at 10 o'clock. The last meal is supper, which is served at 9 o'clock, and consists of bread and cheese. Nothing is served out to the boys in the morning before breakfast, but Mr. Moss says the boys have always plenty of biscuit, which they are at liberty to eat at that time if they require it. The bathing arrangements in the house appear primitive, but they are efficient. Cold bathing is practised by many of the boys throughout the year, and they are particularly attached to the cold douche. During the summer months they bathe in the Severn, some distance above the outlet of the town drainage we are glad to say, and are taught swimming by an attendant; no boy is allowed to enter the water unless he is present. Boating is carried on to some extent by the boys, but none are allowed to row without first having learnt to swim. Three medical men are attached to the school; Dr. Andrews and Mr. A. G. Brookes attend at the head master's house, and Mr. J. R. Humphreys at the second master's. There is no regular medical supervision, and no certificate is required on a boy's entrance or return to school from the holidays. The head master says that as yet the necessity for such precaution has never been forced upon him, as during the eight years that he has had the management of the school there has been no outbreak of fever; he was disposed to think that the suggestion was a valuable one. The numbers being small, and the medical men constantly visiting the school, boys of weak and delicate constitution speedily come under observation, and so, though not in the degree that we should like to see, some sort of supervision is exercised.

Shrewsbury is one of the few schools that has a system of sewerage separate from that of the town. The school sewer is ventilated. Every waste-, sink-, and overflow-pipe, is disconnected from the sewer, is carefully trapped, and empties outside the building over a grating, which is again trapped before entering the sewer. The waterclosets in the house are all ventilated. The consequence is that the interior of the school-buildings, notwithstanding the way in which they are packed together, is perfectly sweet and fresh. The water used in the buildings is from two sources—that for the closet-cisterns is from the town water-supply; the drinking-water is obtained from a conduit near the school, the water of which is brought from springs at Kingsland, so that the drinking water is quite distinct from that used for the closets. The drinking-water is of excellent quality. We ought to say that the second master prefers the water from the Castle-well, and in his house this is used.

The governors, as yet, have not, for want of space, been able to provide a separate sanatorium for infectious cases. Whenever a case of scarlet fever has occurred it has been removed to a cottage in the neighbourhood, and hitherto the accommodation thus obtained has been sufficient. In the event, however, of an outbreak occurring it would be necessary to break up the school. A sick-room, however, is set apart for ordinary cases of illness in the master's house. All boys not in school have to report themselves at once to the doctor, so that in the event of any infectious illness appearing it can at once be isolated. There is no regular playground provided for the boys beyond a slip at the back of the school, on the slope of the hill, on which a fives court is built. Here also are a range of out-door privies and urinals. In one of these urinals we saw an arrangement worthy of general adoption. Instead of the perforated iron pipe, dribbling miserable little jets of water, there was a powerful water-tap turned on, the full stream of which effectually washed away the urine, and kept the place sweet and clean. As there is no regular playground attached to the school, the head master rents a field about half a mile away for the use of the boarders, and hitherto the rent has been defrayed by him, and not by the school.

The great drawback at Shrewsbury, therefore, is want of space, and the evil increases yearly as the school develops. It has been long felt that, as Shrewsbury has gained such a high reputation, some means should be adopted to extend its usefulness and place the school on a basis of permanent prosperity. For twelve years the question of removal to another site has been under discussion, and several attempts have been made to effect it, but have fallen through. Now, however, the governing body have secured from the Corporation a very eligible site at Kingsland, a suburb on the other side of the river Severn. This site embraces every advantage; it is quite separated from the town by the river, yet not too far off to hinder the attendance of the town boys—being, in reality, for many of them, not further than the present buildings. The situation is extremely beautiful, and comprises about twenty-seven acres of ground. It is situate at the top of a hill, at the foot of which winds the Severn, the opposite bank of which is fringed with a noble avenue of trees, which almost hides the town. The soil is dry (of red sandstone), and the natural drainage good. An independent water-supply for the school could be secured from the springs in the neighbourhood. A large brick building at present occupies the brow of the hill, and which for many years has been used as a workhouse. The general feeling of course is in favour of the removal of this edifice and the erection of a building more suitable to school purposes; but we fear the raising of new buildings is a question of money and not sentiment, and the governing body are not wealthy. We think perhaps it would be more prudent to utilise the present buildings till sufficient funds are forthcoming to build a really handsome school. We hope, however, the governing body will not be left unaided in their endeavours to erect a house worthy of the fame of the school. Both Shrewsbury and Shropshire owe much to their school, and liberal donations ought to be forthcoming to aid it on the present occasion.

ARMY MEDICAL SCHOOL.

The thirty-first session of the Army Medical School was opened on the 1st inst. with fifteen candidates for commissions in the medical department of the British Army, ten for H.M. India service, and seven for the Royal Navy. The opening lecture was delivered by Professor Longmore, C.B. The lecturer departed somewhat from the usual course on such occasions; instead of going again into the history of the Army Medical School, and explaining the purpose for which it was founded, Mr. Longmore, after a few words of cordial welcome to the new-comers, referred them for information on all matters relating to the constitution of the school, the instruction given in it, and the duties of candidates for commissions, to addresses delivered on previous like occasions, and to the opening address of Lord Herbert, to be found in the first volume of the Departmental Bluebook. The lecturer then entered on the subject selected for his address—viz., an historical account of amputation from the dawn of surgery to the present time. This important subject was treated in an interesting and exhaustive manner, showing the slow steps by which this commonly supposed simple operation was perfected from the rude and cruel proceedings of the early surgeons up to the bloodless amputations of the present time. As the lecture will be published in a complete form, we need not attempt to give an imperfect summary of it on the present occasion. The lecture was listened to with much interest, and the Professor was loudly applauded at its conclusion.

Correspondence.

"Audi alteram partem."

THE CAUSE OF SEA-SICKNESS.

To the Editor of THE LANCET.

SIR,—In a letter to *The Times* on the merits of the *Castalia*, Mr. Marshall suggests that sea-sickness is due to the pitching of the vessel rather than the rolling, and adds that he should like to see the experiment tried of rocking a person from side to side in a chair, and then up and down, and comparing the effects of the two processes. This experiment, in a modified form, was tried upon myself last year in one of the small Scotch steamboats, and completely corroborated the view I already held, which is the same as that of Mr. Marshall. In various other ways also the trial can be made.

Being myself a very bad sailor and having a very susceptible nervous system, I have for many years studied my feelings during the various movements of a steam-vessel, and have no doubt at what time the greatest distress is felt. Rolling has no effect; the upward movement is not unpleasant; but the downward sinking of the vessel produces a sudden horrible feeling of depression at the pit of the stomach, with a corresponding bewilderment of the brain. Some years ago, when on the Mediterranean, I one day thought myself brave enough to sit down to dinner; and I well remember how I fought against all the other movements of the boat until it descended into a trough of the sea, when the swallowing a piece of food became a perfect impossibility. But the proof I wish to mention occurred in the voyage to Skye when passing between two islands where there was a ground swell, and the vessel slightly pitched; at this time I experienced, in a modified degree, the feeling of sea-sickness, but shortly the boat turned and took its course parallel with the waves; a rocking movement ensued, and my disagreeable feeling immediately passed off. No better proof, however, of the immediate cause of the *mal de mer* can be shown than in the similar sensations produced in descending a lofty building by a lift—as, for example, the Albert Hall. I myself have experienced a feeling of faintness after coming down which I have not thrown off for an hour or two, and I have known of others who could sympathise with me. Yet another example of the same kind. I was in the habit at one time of frequently travelling along a line of railway where at one spot it was slightly elevated to cross a turnpike road. The descent on the other side must have been very slight, but I always experienced a nauseating sensation during the moment when the carriage went up and down.

All these facts would tend to show that the sensations which I have described are due to the sudden falling of the abdominal viscera and their want of due support by the muscular parietes during the act of falling. The explanation is for many reasons not wholly satisfactory, but it seems the best which can be offered. It tallies with the well-known fact of the intense depression which is frequently experienced by persons who are the subject of incarcerated hernia.

In sea-sickness it may be remarked how all the symptoms resemble what is seen in gastro-intestinal affections, how on a warm day the sufferer may become deathly pale, cold, and almost pulseless. It is well known that when the movements of the boat are but slight, the horizontal posture will insure immunity from sickness. Chloral appears to be a good remedy, but whether it acts by simply benumbing the nerves of the stomach or by reducing the susceptibility of the whole nervous system, I am uncertain, but I know that a passenger may take a dose of chloral at Dover, fall into a drowsy, half-conscious state, and find himself at Calais free from sickness. Any explanation of sea-sickness must allow for the different susceptibilities of individuals, and nothing can show better than this horrible malady the great range of temperaments amongst us. Many young persons are ill if they ride in a carriage with their backs to the horses. Has this ever been explained?

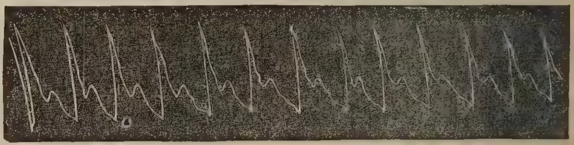
I am, Sir, your obedient servant,

Grosvenor-street, Oct. 1875. SAMUEL WILKS.

A STANDARD SPHYGMOGRAPHIC TRACING (CAPTAIN WEBB'S).

To the Editor of THE LANCET.

SIR,—As it is a matter of considerable interest to physiologists and other students of the sphygmograph to possess a tracing that may be referred to as the type of a healthy, vigorous man, I have taken the opportunity of obtaining that of Captain Webb. It will be seen that it is a magnificent example of perfect elasticity of the arteries and action of the heart. In connexion with Captain Webb's recent feat of strength and endurance, it is especially interesting to put this tracing on record.—Yours, &c.,



Weymouth-street, W. FANCOURT BARNES.

REGISTRATION OF DISEASE.

To the Editor of THE LANCET.

SIR,—I beg leave to call your attention to, and request your correction of, a typographical error of some importance which has crept into your otherwise accurate and favourable notice of my annual report on the health of Customs officers which appeared in THE LANCET of October 2nd, under the title of "Registration of Disease."

Therein it is stated that the mean daily number on the sick-list (30·7) was in the ratio of 6·4 per cent. on strength, and that the death-rate was 2 1 per cent. on strength. These proportions are erroneous, and far higher than have ever occurred in the force. The true ratio of sickness—*id est*, mean daily number incapacitated for duty—in the year 1874 was 3½ per cent., and the mortality-rate (including accidental deaths) was 1·3 per cent. These latter proportions vary but little from the annual average, which, deduced from the records of many years, shows a sick-rate of 3 per cent., and a mortality-rate of 1·2 per cent.; or, to use the more familiar ratio of comparison, 12 per 1000.

I have the honour to be, Sir, your most obedient servant,

Custom House, October 13th, 1875. WALTER DICKSON.

BIRMINGHAM.

(*From our own Correspondent.*)

ACTING on the recommendation of the medical officer of health, Dr. Alfred Hill, the Town Council to-day decided to avail themselves of the advantages offered by the Artisans' and Labourers' Dwellings Improvement Act. The unhealthy area, which Dr. Hill describes "as in such a state of dangerous dilapidation that it is unfit for human habitation," and "affording only receptacles for rubbish and filth, and constituting a danger of the gravest kind to the health and well-being of the whole town," is situate in the centre of the town, and contains the homes of 9000 persons. The scheme unanimously adopted by the Council, after two days' discussion, will involve the purchase of forty-five acres and a half of land, at an estimated cost of over half a million of money. The necessity for sanitary interference in this district is proved by the fact that in the ward which is mainly to be dealt with the mortality is 26·82 per 1000, or twice as great as that of Edgbaston ward (13·11), in which there are no factories, and in which the houses are mostly new and properly built and drained.

Another step which the Corporation have wisely adopted is to keep the public swimming baths open during the winter season. There can be no good reason why this great boon to the working classes should be restricted to the summer months. Then they can avail themselves of the pools and rivers in the neighbourhood of the town, but in the winter there is no chance for them to wash and be clean unless some such bath is open to them.

The deputy coroner has called attention to the alarming fact that from 150 to 200 infants are overlain in this town annually. Negligent mothers who disregard their infants must be dealt with more stringently than they are now, when the jury seem invariably to return a verdict of "found dead," and one or two prosecutions for manslaughter at the assizes would probably tend to diminish this growing crime.

The introductory lecture at Queen's College was given to a crowded audience of old and new students by the Warden, the Rev. W. H. Poulton, M.A., the chair being taken by Dr. Bell Fletcher. The lecturer called attention to the length of time many students wasted at the College and hospital without presenting themselves at any of the examining boards, and suggested as a remedy, that any student who presented himself for examination after the prescribed period of study should be subjected to a more stringent examination. He also inveighed against the tendency of the present day to multiply prizes out of all proportion to the perseverance expended in their acquisition, and against the practice of students holding assistantships during their first and second years at college.

The inaugural clinical address was given by Mr. Alfred Baker, at the General Hospital, on the 8th inst. It was full of sound practical advice to the students, to whom he commended the example of John Hunter, and was received most heartily by a large gathering of the old as well as of the rising members of the profession. The entry of students this year is said so far to be above the average.

Antiseptic dressings have been used recently at the General Hospital, and they have given some extremely successful results. In a case of empyema under Mr. Pemberton, where the chest was opened antiseptically and a drainage-tube run through it, the man has gained weight in a remarkable manner. Another good case is that of an epithelioma of the axilla and of the gluteal fold in a chimney-sweep. The former was in close relation to the axillary artery. There have also been two cases of dislocation of the foot inwards from the astragalus (one, which was compound, dressed antiseptically), and in neither was there any difficulty of reduction under ether, and both made a good recovery.

At the Queen's Hospital Mr. Jordan performed resection of the hip-joint on a young man who had long suffered from hip disease, which had produced partial anchylosis. The case is going on well. Colotomy has recently been performed for cancerous obstruction of the rectum by Mr. West, in a middle-aged man, with success. A melanotic tumour, as large as an orange, was removed on Saturday last from the axilla of a woman, aged forty, which had been growing twelve months.

Birmingham, October 12th, 1875.

MANCHESTER.

(*From an occasional Correspondent.*)

The Medical Department of the Owens College was opened for the session on October 4th, with the usual ebullition of physical approval, by an address from Professor Lund, published in your issue of last week.

During the recess, every opportunity has been taken to let a little more daylight into the fine dissecting-room of the new Medical School, which the experience of last session proved to be unpleasantly shady in the average Manchester daylight. A couple of projecting windows have been let into the roof, and, without impairing the architectural effect, will add much to the comfort of the students.

The new museum is nearly completed, as also the library, where the books of the Manchester Medical Society will shortly find another home. A reading-room will be added in time, and admission will be allowed, under certain restrictions, to the students attending classes.

The chief topic of interest to the profession for some time past is the decision of the Infirmary Board in favour of removal to Oxford-road, in close contiguity to the Owens College. A large piece of land, admirably suited to the purpose, has been secured, and a building containing probably double the present number of beds will be erected. A receiving-house for accidents and urgent cases will be established near the site of the present hospital. There have been many letters in the local papers, by no means entirely in favour of the proposed removal, but there can be little doubt that the plan pursued by the infirmary authorities will prove the best in the end.

One or two of the suburbs of Manchester have had rather severe forms of enteric fever and scarlatina.

The medical officers to the provident dispensaries have just decided to resign, almost *en masse.* Their experience of the present working arrangements, and the treatment received at the hands of the General Council (which does not contain any representatives of their body), have proved eminently unsatisfactory to the small band who have hitherto supported the scheme.

Manchester, October 12th, 1875.

PARIS.

(*From our own Correspondent.*)

THE APPROACHING WINTER SESSION OF THE PARIS SCHOOL OF MEDICINE.

In a few days the School of Medicine will open for its winter session. Before its opening, however, some important changes will have taken place in its teaching *personnel.* Thus, Professor Wurtz, the dean, has sent in his resignation. The school is without a dean, and has been so for some time, as the greatest difficulty is experienced in finding a new one. The *décanat*, or deanship, of the Paris Faculty is no sinecure. The dean must be rather popular with the students, and yet have sufficient authority and firmness to subdue the "manifestations" which they make every now and then. He must also be a good administrator, so as to keep the Faculty in business order, and look after its financial matters. It is said that this was the weak point of the last dean, who, possessed of every possible quality as a professor, a *savant*, and a gentleman, overlooked the business department of the school. Financial matters got muddled through the fault of subordinate officers, and the dean, disgusted with the results, sent in his resignation. He of course retains his chair of Chemistry, and the students will not be deprived of his brilliant lectures this winter.

Meanwhile, no one cares to take his succession as dean. There was a talk of Professor Gosselin accepting, but he has decidedly refused. Professor Depaul was also spoken of, but he has gone over to Brazil to accouche the Emperor's daughter-in-law. At present Professor Vulpian is most earnestly solicited to take the post, and will very likely end in accepting it, notwithstanding some reluctance.

Another important change in the Faculty will be the formal disappearance of the venerable and renowned Bouillaud from the teaching of the school. It is true that for the last few years he generally had some of the vice-professors of the school to lecture in his place at the Hôpital la Charité. Still his name figured in the programme and amongst the professors, with the lustre which it sheds. Now he definitely retires from the arduous scene of clinical work and teaching, though he is yet full of life and vigour, and his abilities are as bright and active as ever. But he has well won his laurels, and is at liberty to take his *otium cum dignitate* when he pleases.

His retirement from the clinical chair of La Charité will necessarily entail the appointment of a successor. As you know, it is the professors of the school who elect a new colleague whenever a vacancy occurs. They generally select their colleagues out of the body of vice-professors, or *agrégés*. They choose two names, which are presented to the Minister of Public Instruction for selection, and he invariably nominates the first on the list. On this occasion it is very likely that one of the professors of the school, Dr. Hardy, Professor of Internal Pathology, will be allowed to change his chair for the vacant one of Clinical Medicine; and one of the *agrégés*, very likely Dr. Jaccoud, will be elected to Dr. Hardy's chair. Dr. Hardy is the well-known teacher and writer on skin diseases, whose clinical lectures on dermatology at St. Louis have been as successful as his theoretical teaching on medicine at the Faculty.

WINTER PROGRAMME OF THE PARIS SCHOOL.

Whilst on this subject, no doubt a statement of the winter programme of the Faculty will be read with interest. The professor of anatomy, M. Sappey, will lecture on the principal systems and the principal regions of the body, whilst Professor Robin will lecture on histology and make a special study of each of the organic tissues and systems. The theoretical teaching of surgery is divided between MM. Dolbeau and Le Fort, the former of whom will lecture on general surgical pathology, and the latter on "the therapeutics of affections of the circulatory system," and "the operations performed in diseases of the eyes, the mouth, and the chest." In Medicine M. Duguet (Medical Pathology) will lecture "on diseases of the urino-genital organs in man and woman"; and Prof. Chauffard (General Pathology and Therapeutics) on "acute and chronic disease, their symptomatology and etiology." The Professor of the History of Medicine, M. Lorain, will lecture this year on "the historical aspects of some contagious diseases—small-pox, syphilis, &c." The sister sciences will include Prof. Gavarret's lectures on the physical phenomena of speaking and hearing, and Prof. Wurtz on the study of the blood and the chemical phenomena of respiration and nutrition. The practical teaching of the school is carried on in the hospitals, and includes Professors Béhier and Richet at the Hôtel Dieu; Gosselin and Sée at La Charité; Verneuil and Lasègue at La Pitié; Broca at the Hôpital des Cliniques; and Depaul in the lying-in wards of the same hospitals. Dr. Blachez will also deliver a series of supplementary lectures on pædiatrics at the Hôpital des Enfants.

DEATH OF MARBEAU, THE FOUNDER OF CRÉCHES.

A man of worth and usefulness, François Marbeau, the founder of *créches*, died yesterday. He was an assistant-mayor at one of the mairies of Paris, when, being appointed to visit some asylums, he had occasion to notice that a great many workwomen were obliged to give their babies in keeping, to pay sevenpence a day for the purpose, and to go twice a day to suckle their children in the asylums. The idea occurred to him of establishing homes under the direction of sisters of mercy, provided with medical attendance, cradles, and every possible comfort and *surveillance*, and where workwomen's children might be kept safely and fed during their labour hours. The first *créche* was founded in 1844, at Chaillot, and proved most successful. The number of *créches* in Paris is now thirty-four, and in the departments eighty.

François Marbeau from that time continued to devote his life to the success of the institution he had founded, and to other charities. His life was one of general usefulness, and he is universally regretted.

ILLEGAL PRACTICE OF MEDICINE IN FRANCE.

There is at present a general outcry in France against the amount of illegal practice of medicine, which is doing the greatest harm to the regular practitioners, and is gradually cutting down the number of medical men who will consent to practise in the country. Everybody seems to meddle more or less with medicine; but those who *sell* medical advice or drugs, to the prejudice of qualified medical men, and without being authorised in any way, are most culpable, and their number is legion here. The provincial special and general papers are very earnest on the subject. One of them, the *Decentralization*, a political paper of Lyons, cries out that it is high time to put a stop to the practice in the interest of the public. It quotes the fact of chemists opening abscesses and prescribing, religious congregations selling eye-salves, midwives applying plasters to strangulated umbilical hernia, a renowned individual purging consumptive sufferers to death with a quack medicine, and winds up with an authentic history of a somnambulist who charged three francs for the following advice to a rheumatic individual:—Take two live tenches and apply them to the calves of the legs; take some little onions and apply one of them between each two toes; and take some bitter drink to finish up the cure.

THE PARIS HOSPITALS AND CLINIQUES.

In addition to the official teaching mentioned above, I may state that the various private lecturers in the hospitals are also busy preparing for the forthcoming *rentrée*. Dr. Michel Peter will continue his series of brilliant and instructive lectures at the St. Antoine; Dr. Bucquoy is to lecture at Cochin; Fournier at Lourcine or the Lock Hospital, on the venereal diseases of women; Panas, on eyes, at Lariboisière; and Gallard, on women, at La Pitié. Dr. Isambert will also continue his lectures on the larynx and his practical demonstrations of the uses of the laryngoscope, which he inaugurated so successfully last winter.

Paris, October 12th, 1875.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Oct. 7th:—

Boswell, Alexander, Disraeli-road, Putney.
Johnstone, William, Seaforth, Liverpool.
Low, Frank Harrison, Aberdeen House, Blackheath.

The following gentlemen passed the Primary Professional Examination on the same day:—

Reeve, Henry, London Hospital.
Roberts, Henry William, Guy's Hospital.

THE subscriptions to the proposed memorial to Sir John Gray, M.P., have already reached £500.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—A meeting of the Council will be held on Friday (this day) for the purpose of considering what shall be the future policy of the Association, the action to be taken in support of the Maunsell Testimonial, and for general business.

ST. BARTHOLOMEW'S HOSPITAL.—The Abernethian Society, composed of the teachers and students of the hospital, holds its meetings in the reading-room, every Thursday evening during the winter session, for the reading and discussion of papers on subjects of medical science or practice, and for the exhibition of pathological specimens.

DUBLIN HOSPITAL SUNDAY.—At a late meeting of the Executive Council of the Dublin Hospital Sunday Fund communications were received from the secretaries of the Meath Hospital and the Convalescent Home, enclosing resolutions to the effect that the committees of those institutions desired that they should participate in the movement. The Meath Hospital was one of those institutions which heretofore refused to have any share in the funds collected, and we are glad to find that its governors have seen their mistake. The Adelaide Hospital, however, another of the objectors, still declines to have anything to do with the movement.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At the annual meeting, held in July last, the following officers were elected for the ensuing year:—President: Dr. G. Buchanan. Vice-Presidents: Dr. Thos. Stevenson, Dr. G. Ross, Dr. F. T. Bond. Treasurer: J. Liddle, Esq. Secretaries: Dr. J. Northcote Vinen, Dr. W. H. Corfield. Council: Dr. J. Adams, Dr. C. O. Baylis, Dr. M. Corner, Dr. T. O. Dudfield, Dr. C. B. Fox, E. L. Jacob, Esq., Dr. P. Jones, Dr. H. G. Sutton, H. Leach, Esq., Dr. C. M. Tidy, Dr. J. T. Tripe, Dr. W. T. G. Woodforde.—The first meeting of the session will be held at the Scottish Corporation Hall, Crane-Court, Fleet-street, on Saturday, October 16th, at 7.30 P.M., when the president will deliver an inaugural address "On some Directions of Scientific Work by Medical Officers of Health."

West Kent Medico-Chirurgical Society.—The opening meeting of the twentieth session was held on Friday, Oct. 8th, at the Royal Kent Dispensary, Greenwich-road, Dr. John Anderson in the chair. The following members were elected officers for the session 1875-76:—President: Dr. J. N. Miller. Vice-Presidents: Dr. Thomas Creed and Mr. J. P. Purvis. Council: Drs. John Anderson, William Carr, Ralph Gooding, and Messrs. Hughes Cable, William Churton, Frederick Moon, and William Lockhart. Treasurer: Dr. Prior Purvis. Secretary: Mr. H. Knight Hitchcock. Librarian: Mr. J. B. Saundry. The next meeting will be held on Friday, Nov. 5th, at 8 P.M. precisely, when Dr. Braxton Hicks will read a paper.

Medical Appointments.

Baber, E. C., M.B., L.R.C.P.L., M.R.C.S.E., has been appointed Resident Medical Officer to the Atkinson-Morley Convalescent Hospital, Wimbledon, vice Owen, whose appointment has expired.

Barlow, C., M.R.C.S.E., has been appointed Medical Officer for the Sutton Coldfield District of the Aston Union, vice Smith, deceased.

Bernard, A., M.B., L.R.C.S.Ed., has been appointed an Honorary Medical Officer to the Liverpool North Dispensary, vice Walby, resigned.

Brown, Mr. F. W. (London Hospital), has been appointed Resident Clinical Assistant at the Hospital for Consumption and Diseases of the Chest, Brompton, vice Blakiston, whose appointment has expired.

Chambers, Eber, M.B., C.M., M.R.C.S.E., has been appointed House-Surgeon to the Chester General Infirmary.

Cooper, J. C., M.R.C.S.E., has been appointed House-Surgeon to the Midland Counties Hospital for Chronic and Incurable Diseases, Leamington.

Dale, G., M.B., C.M., has been appointed Medical Officer for the Patterdale District of the West Ward Union, Westmoreland.

Davidson, G., M.B., C.M., has been appointed Medical Officer to the West Pelton Lodge of the Durham Miners' Association.

Dyke, T. J., F.R.C.S.E., has been reappointed Medical Officer of Health for the Merthyr Tydfil Urban Sanitary District for six months.

Foulds, S., L.R.C.P.L., M.R.C.S.E., has been appointed an Hon. Medical Officer to the Chesterfield and North Derbyshire Hospital and Dispensary, vice Booth, resigned.

Glasier, C., M.B., C.M., has been appointed House-Surgeon and Secretary to the West Norfolk and Lynn Hospital, vice Reid, resigned.

Hall, F. de H., M.D., M.R.C.P.L., has been appointed an Assistant-Physician to the Westminster Hospital, vice Sturges.

Hicks, C. C., M.D., M.R.C.S.E., has been appointed Medical Officer for the Upper District of the Leighton Buzzard Union, vice Bothwell, resigned.

Hunter, T., L.R.C.P.Ed., L.F.P. & S. Glas., has been appointed Medical Officer to the Teesdale Medical Union.

Imlach, F., M.D., M.R.C.S.E., has been appointed an Honorary Medical Officer to the Liverpool North Dispensary, vice Lewtas, resigned.

Jones, E. O., M.B., C.M., has been appointed Medical Officer and Public Vaccinator (temporarily till Christmas) for the No. 3 District of the Oswestry Incorporation of the Poor, vice Davies, deceased.

Keys, R. A., L.R.C.P.Ed., L.M., F.R.C.S.Ed., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Castlefin Dispensary District of the Strabane Union, Co. Tyrone, vice Smith, resigned.

King, T., M.D., M.R.C.S.E., has been appointed Certifying Factory Surgeon for Rochford.

Le Quesne, E. J., M.R.C.S.E., has been appointed Assistant House-Surgeon to the Metropolitan Free Hospital, Devonshire-square, vice Harvey, whose appointment has expired.

Long, H. P., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Eythorne District of the Eastry Union, Kent, vice Williams, resigned.

Mac Ewan, A. C., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Visiting Surgeon to the Chester General Infirmary, vice Chambers, appointed House-Surgeon.

Parkinson, C. H. W., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the No. 1 District of the Wimborne and Cranborne Union, vice C. B. Parkinson, M.R.C.S.E., deceased.

Peele, E., L.K.Q.C.P.I., L.R.C.S.I., L.M., has been appointed Medical Officer for the No. 2 Division of the South City Dispensary, Dublin, vice Maunsell, deceased.

Powell, H. M., M.R.C.S.E., has been appointed Visiting Medical Officer to the Dispensary for Sick Children, Gartside-street, Manchester, vice Renshaw, resigned.

Roberts, A., M.R.C.S.E., has been appointed Medical Officer for the North Keighley District of the Keighley Union, vice Cockcroft, resigned.

Sturges, O., M.D., F.R.C.P.L., has been appointed a Physician to the Westminster Hospital, vice Sir G. D. Gibb, Bart., M.D., resigned.

Taylor, F. E., M.R.C.S.E., has been reappointed Medical Officer of Health for the Wells, Norfolk, Urban and Port Sanitary Districts.

Taylor, Mr. H. E., has been appointed a Resident Medical Officer to the General Infirmary, Leeds, vice Ellerton, whose appointment has expired.

Thomson, A., F.R.C.S.I., L.M. K.Q.C.P.I., has been appointed Assistant Medical Officer to the Barnwood House Hospital for the Insane, Gloucester, vice Pilcher, whose appointment has expired.

Wearing, R., M.B., C.M., has been appointed Assistant Resident House-Surgeon to the North Dispensary, Liverpool, vice Blake, resigned.

Wilkins, Mr. R. B. (Univ. Coll. Hosp.), has been appointed a Resident Clinical Assistant at the Hospital for Consumption and Diseases of the Chest, Brompton, vice Orr, whose appointment has expired.

Wilson, J. M., M.B., C.M., has been appointed Medical Officer of Health for the Rochdale Urban Sanitary District: £300 per annum, with all office requirements.

Wyke-Smith, W., L.R.C.P.Ed., L.M., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for No. 2 District of the Wimborne and Cranborne Union, and Medical Officer to the Workhouse, vice Chas. H. W. Parkinson, M.R.C.S.E., resigned.

Births, Marriages, and Deaths.

BIRTHS.

Bassett.—On the 7th inst., at Hockley-hill, Birmingham, the wife of John Bassett, M.D., of a son.

Bland.—On the 10th inst., at Park-green, Macclesfield, the wife of Geo. Bland, L.R.C.P.L., of a daughter.

Messer.—On the 7th inst., at Helensburgh, the wife of T. J. Fordyce Messer, M.D., of a daughter.

Moore.—On the 6th inst., at the Pembroke Royal Dockyard, the wife of Geo. Moore, M.D., Fleet-Surgeon R.N., of a daughter.

Skues.—On the 2nd inst., at Lonsdale-square, the wife of Dr. Skues, Staff Surgeon-Major, Malta, of a son.

MARRIAGES.

Curran—Fyson.—On the 7th inst., at Christ Church, London, Dr. Curran, of Lew Down, Devon (eldest surviving son of Thomas Curran, Esq., of Ennistimon, Co. Clare, Ireland), to Sarah, third daughter of the late Wm. Fyson, Esq., of Exning, Camb.

Thomson—Cose.—On the 6th inst., at Beechwood, Lochee, Wm. Thomson, M.D., of Peterborough, to Jessie Methven, only daughter of George Addison Cose, Esq., of Invertrossachs, Perthshire.

Woodman—Allen.—On the 9th inst., at St. Mark's, Torquay, John Woodman, F.R.C.S.E., of Exeter, to Catherine Louisa, daughter of the late Rev. John Allen.

DEATHS.

Bennett.—On the 4th inst., at Worksop, Edwin Bennett, M.R.C.S.E., aged 47.

Dunlop.—On the 6th inst., at Greenock, Dewar Dunlop, L.F.P. & S. Glas., aged 55.

Forsyth.—On the 6th inst., at Templeard, Culmore, Geo. Crompton Forsyth, M.B., aged 22.

Furnivall.—On the 2nd inst., at Egham, Edward T. Furnivall, M.R.C.S.E., aged 41.

Kay.—On the 1st inst., at Alverstoke, John Kay, Deputy Inspector-General of Hospitals and Fleets, aged 82.

Leeds.—On the 6th inst., at Castle-hill, Brenchley, Kent, Hannah, the wife of Edward Leeds, M.B., M.A., M.R.C.S.E., aged 34.

Manford.—On the 5th inst., at Ness Bank, Inverness, Robt. A. Manford, M.D., aged 66.

Matthews.—On the 7th inst., at Maida-vale, Robt. Hughes Matthews, M.R.C.S.E., aged 70.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

Reports of Medical Officers.

Medical Officers of Health will greatly assist some inquiries we are prosecuting into the sanitary condition of the country, if they will forward to us copies of reports made or issued since the passing of the recent Acts of Parliament.

A New Medical Journal for Paris.

We have received the first number of the *Paris Médical*, a weekly journal to be devoted to practical medicine and surgery. It is edited by Prof. J. A. Fort, who, in explaining the aims and objects of his enterprise, says that it finds its *raison d'être* in the present neglect of therapeutical instruction from which the students of Paris are suffering—a neglect which has found its result in the recent official report addressed to the Minister of Public Instruction by the President of the late "Concours d'Agrégation en Chirurgie." In that report M. Ridet points out that, although the results of the recent examinations were such as to show very extensive pathological and clinical knowledge on the part of the candidates, as regards treatment and the indications for treatment, their knowledge was lamentably deficient. Dr. Fort proposes, then, to fill up this hiatus in medical education; and in his journal, which is to have none of its articles signed, in order that perfect freedom may be left to the writer and reader, he will draw attention to practical medicine and surgery. The first number is, however, too much occupied by the editor himself for us to judge of its merits, since not only does he contribute the aforesaid address, but he also devotes some pages to a description of the last edition of his General and Descriptive Anatomy, a course for which, however, he duly apologises. In spite of this, the aims of the journal are good, and we wish it success.

Surgeon-General Dr. Maclean is thanked for his courtesy.

Foot-and-Mouth Disease.

To the Editor of The Lancet.

Sir,—As this disease is very prevalent in Warwickshire, and as many cases of aphthous sore mouth and throat are now to be found (amongst the working classes especially), I should be very glad to have replies to two queries:—1st. Is foot-and-mouth disease seriously believed to be communicable to the human subject? 2nd. What are the safest tests of suspected milk during the continuance of the epizootic? Yours truly,

Coventry, Oct. 13th, 1875. A Subscriber.

"MADE GROUND."

A CONTEMPORARY recently called attention to the peril of placing new residential property upon a foundation consisting of "old cabbages, fish-bones, old shoes, &c.," to the depth of five feet. We fear the practice of "making ground" by levelling up with "rubbish" of every description is not only widespread, but almost universal. The custom, when a piece of land intended as the site for an "improvement" requires raising, is to let it to some contractor, who immediately sublets it to a nondescript tradesman, who emblazons the site with a placard, "Brown's Shoot," "Robinson's Tilt," or "Rubbish may be shot here." If possible a hoarding is put up round the land; in any case a barrier of some kind is erected, and the speculator either himself takes a toll from the carts which congregate to the spot, or places an old man or woman to perform that pecuniary service on his behalf. This method of procedure is so commonly adopted that it is even pursued in the case of pleasure-gardens. More than one square in a populous district of London has been recently "levelled-up" with decomposing matters collected by the open "shoot." A year or two hence, when the land has settled, and the surface soil has been washed down, a putrefying surface will be exposed, and perhaps an outbreak of fever in the row of houses overlooking this elegant garden—so healthful for the children to play in—will perplex the local practitioners. It is absurd to go to the expense of closing intra-urban graveyards and removing nuisances, by costly expenditure, if we create new beds of pest-breeding rubbish, and call them "made-ground." The remedy officially proposed is to cover up the evil with a layer of concrete. This may be the only practicable plan where the mischief is done; but the practice should be summarily interdicted.

"ABUSE OF MEDICAL CHARITY."

To the Editor of THE LANCET.

SIR,—I shall feel obliged by your inserting the following correspondence, in reference to my letter in THE LANCET of the 25th ult., in your next number.
I am, Sir, yours truly,
Cirencester, Oct. 11th, 1875. EDWARD CRIPPS.

Greenhill, Weymouth, Oct. 8th, 1875.

DEAR SIR,—In last week's LANCET I observe a letter from you, stating a patient of yours had come to the Sanatorium at Weymouth for advice gratis, and had since got her medicines at the druggist's from the prescription there given her, and that you were thereby deprived of your patient, &c. &c. I think it better to write to you rather than to THE LANCET, to disabuse your mind of any desire on the part of the medical officers of the Sanatorium to provide for anyone but those for whom the institution was established. Indeed, if a grievance be at all felt, I am sure you will agree with me that I have rather the right to complain of one in the position of your patient coming for advice gratis, depriving, if not robbing, me of one guinea; but even had she come to my house for advice, and paid my fee, she might still have taken the prescription to a chemist's, though I might, as is my custom, advise her to take it to her own medical man.

However, my chief object in writing you is to make you acquainted with the Sanatorium, which I have founded, and have had endowed, more especially as its portals are open to receive in-patients from all parts of the United Kingdom, and you may perchance have in your district some poor sufferer, for whom you would like to secure good nursing and sea air at a rate compatible with her circumstances—one, in fact, who could not afford to pay for lodgings, much less for medical attendance, and for such a one is the Sanatorium more especially founded; and if you know of any such to send, I need not say how much pleasure it will give me to treat them in the Sanatorium; or if you send a note with an out-patient unable to pay for advice, I shall be equally pleased to advise their course while here by their coming to the Institution twice a week, and will ask them to take the prescription to you on their return. You will better understand the nature of the Weymouth Sanatorium by seeing and reading the annual reports, and I have much pleasure in sending you those of last and previous years.

Believe me very faithfully yours,
Ed. Cripps, Esq. WM. J. SMITH.

Cirencester, Oct. 11th, 1875.

DEAR SIR,—I have received your letter, also the prospectuses, reports, &c., of the Weymouth Sanatorium. You will excuse me for saying, however, that all this is beside the question at issue. In my letter to THE LANCET I upheld the practice of your institution as typical of the abuse of medical charity. You reply, first, that my patient has deprived *you* of a fee by coming to your institution instead of consulting you privately, and that the practical result to me would be the same in either case; and secondly, that "I may perchance have in my district some poor sufferer for whom I should like to secure good nursing and sea air at a rate compatible with her circumstances, and who could not afford to pay for medical attendance."

To the first, I reply that whether you deprive yourself or me of a fee it matters not; you do an equal injustice to the profession in either case. And secondly, I admit that I have such poor sufferers in my district who cannot afford to pay for medical attendance, but that the patient in question is not such a one. The fact is, the case is so simple that there is not much to be said about it. A patient, perfectly well to do, and as well able to pay her way as you or I, is able, by the indiscriminate way in which your "portals" are thrown open, to obtain gratuitous advice and medicines, without any "recommendation," and without any questions being asked as to her circumstances. This, I say, is an abuse of the word charity, and does an injustice to the profession. Surely a little care and discrimination would easily enable you to become aware of the class of many of your out-patients. To show that I am not singular in my ideas on the subject, I could quote from a letter which I have received from one of the most respectable medical men in the county of Wilts, in which he speaks most strongly of the injury done by your instititution to the local medical men.

I am yours truly,
Dr. Smith. EDWARD CRIPPS.

P.S.—Although you say you prefer sending me a private note to answering my letter publicly, I feel that, as my first letter was published in THE LANCET, I ought to publish your letter and this reply.

POISONING BY GOAT'S MILK.

WE have received a pamphlet by Prof. Toscani, giving a minute description of this occurrence. It would appear that in a locality of Rome, called Borgo Nuovo, near the Piazza Pia, twenty persons belonging to seven distinct families were seized soon after partaking of goat's milk and bread early in the morning, either mixed with coffee or plain, with symptoms of prostration, irritation of bowels, cramps, convulsions, &c. The milk was obtained from only one goat-keeper. The latter, as is usual in the month of June, came every morning into Rome with a herd of twelve goats, taking his stand in the Piazza Pia to supply his customers. It should be noticed that such members of the seven families who did not partake of the milk remained in good health. Prof. Toscani, in his pamphlet, which is a reprint from the *Archivio di Medicina*, Nos. 7 and 8, 1875, gives full details of the symptoms presented by the patients, none of whom died from the accident, and states that the principal remedial means employed were oil of sweet almonds, large draughts of water containing magnesia and albumen, tamarinds, and ether in a few cases. By order of the authorities, careful investigations were made as to the health of the goats, the vessels into which the milk was drawn, the state of the cups used by the patients, and especially the plants which the goats had used for food, either in the residence of the herd or travelling along from the country into Rome. No positive clue was obtained; but it became probable that elaterium or colchicum was the principal factor in the accidents. Very minute quantities, however, must have reached the stomach of the sufferers, as the goats remained perfectly healthy.

INTRODUCTORIES AND GENERAL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—I think if previous lecturers at the "introductories" in October had drawn a picture so startling as that Mr. Davy drew in his recent lecture at the Westminster Hospital, many aspirants would be deterred from entering our overstocked profession, and reserve their brains and energy for a field where they would be more appreciated, at all events better *paid*. There is no doubt of the usefulness—nay, almost *necessity*—in these days, of being "independent" of the profession, if one would succeed in it; for the hard up-hill work, ever-raging competition, and miserably low fees of the general practitioner (and these latter often never forthcoming!) make it really a serious question whether our lecturers do right in painting the profession in such brilliant colours as they generally do at the "introductories," when it is, in reality, one where the prizes are few and blanks many.

Now, Sir, were it the custom for the general practitioner to receive his fee as promptly as the consulting physician or surgeon does, instead of waiting a year or longer, as he generally has to do, the state of things so many young *dependent* men (amongst whom I am thankful it is not my misfortune to be) complain of might be remedied, and they be better enabled to meet the demands made upon them. In some towns the general practitioner insists on cash payments from his poorer patients, and an old fellow-student of mine, thus fortunately located, tells me it is as popular with the patients as their doctors! Bad debts (alas! so numerous) are thus unknown, and the *dependent* practitioner knows what he may fairly rely upon. As it is now, to get a patient is one thing; but to obtain the fee quite another, very often. This credit necessity from the practitioner is what so often leads to his downfall, and it was only a few days ago that I heard of a surgeon leaving his house suddenly, many of his tradesmen being heavy losers thereby, while with the proposed *cash* payments he would likely have found no necessity to have done so.

Could not some change be effected before those now young become old? It must be unanimous, though.
Your obedient servant,
October 6th, 1875. M.R.C.P.

THE FREE UNIVERSITIES IN FRANCE.

SOME of these, by the incessant labour of the higher ecclesiastics, will enter upon their duties this autumn. Hitherto no faculty of medicine connected with these Universities has been attempted, as clinical instruction cannot be given as long as the Board of Hospitals in Paris keeps aloof. This Board is independent of the faculties, and to some extent of the Government. We hear, however, that at Lille the Board has consented, for a sum of £5600, to grant clinical instruction. The Faculty of Paris is, however, sounding the alarm; for the professors have induced the Minister of Public Instruction to appoint a Committee to report upon the improvements which might be introduced into the modes of clinical teaching and on other desirable changes. In the meanwhile a new branch of study has been annexed to the Paris Faculty of Medicine—viz., anthropology,—with a very efficient staff of professors. This is the work of M. Broca, the eminent anthropologist.

Mr. W. H. Williams.—The rule varies. A distinct understanding should be come to before completing the engagement. The privilege could not, we imagine, be claimed as a matter of right.

THE BODY OF THE LATE JEREMY BENTHAM.

To the Editor of THE LANCET.

SIR,—In THE LANCET of October 2nd a correspondent inquires as to where the body of the late Jeremy Bentham now lies, which is answered by "J. T." quite correctly in the last number of the same journal.

Allow me to supplement "J. T.'s" information by adding that a public demonstration of the muscles of the body was given by Mr. R. D. Grainger on the day following Dr. Southwood Smith's lecture, the dissection for the demonstration being made by myself and two or three of the other senior students of the Webb-street School of Anatomy. The head was desiccated under the receiver of an air-pump by the aid of strong sulphuric acid by Mr. Cooper, the Lecturer on Chemistry; and the skeleton put together by Mr. Appleton, Prosector of the School.

I am, Sir, yours truly,
St. Leonard's-on-Sea, Oct. 13th, 1875. THOMAS LLOYD, M.D.

HOSPITALS AND CHARITABLE ESTABLISHMENTS IN COLOMBIA.

A RECENTLY issued Consular report says that the Spaniards left in many parts of their South American colonies numerous establishments of this kind. They were all connected with the Church, and, in the majority of cases, possessed considerable revenues. Although a great number of these have disappeared, owing to repeated confiscations and the exigencies of frequent revolutions, some still exist. They are now supported by State aid increased by voluntary contributions. In Bogotá there is a fair provision of benevolent institutions, and many private individuals give up their time and labour to them gratuitously. Within the last four years a number of French Sisters of Charity have been introduced, who have done much good.

A. B. C.—Our Students' Number will supply the information required.

MAUNSELL MEMORIAL FUND.

CONVALESCENT HOMES.

To the Editor of THE LANCET.

SIR,—I have never had a desire to rush into print; but as a constant subscriber to your journal of nine years' standing, I feel that I have a right to defend a valuable institution, with which I am connected, from a wholly unmerited attack.

The young man to whom allusion is made by your correspondent is a poor clerk, who is delicate, and was at the time knocked up by work. Many hospital and private nurses, school teachers, scripture readers, City missionaries, and others, who have succumbed to their arduous duties, and would be ill if it were not for rest, are admitted in the course of the year, and surely no objection can be made to the reception of such cases. I believe, and I have had considerable opportunities of observing here and elsewhere, that the Home is less abused in this way than most other charitable institutions. It does not profess to be a hospital, and it is quite true that the male and female inmates do dine together under proper supervision. I think he must be a veritable "Simon Pure" who objects to this. Of course, publicity is the only means of correcting many abuses; but I fancy a little more experience would have led your correspondent to make further inquiries before attacking a useful charitable institution, especially when he learns that the deficiency in income has hitherto been made good out of the private purse of Mrs. Rusher, the founder and manager, and that many of the "rambles" consist of drives in the private carriage of the Rev. W. Hinde, Mrs. Rusher's brother-in-law, who gives his services as Secretary and resident Chaplain altogether gratuitously.

I have neither time nor inclination for further correspondence on the matter, and I remain, Yours obediently,

Quay House, Dover, Oct. 11th, 1875. THOS. W. COLBECK.

To the Editor of THE LANCET.

SIR,—If your correspondent, Mr. Morton, will look to last year's October number of *Good Words*, he will see that there is another side to Mrs. Rusher's Home than the one he describes in his letter.

Mrs. Rusher's Home is designed not only for convalescents, but for overworked, delicate *poor* people, to whom a "holiday at the seaside" is of great service. I venture to think that most medical men, on the principle that prevention is better than cure, will say what a capital institution this must be. Many of my poor parishioners and the young man in question have much to thank Mrs. Rusher for. No doubt, many London incumbents can say the same. Your obedient servant,

GEORGE H. W. BROMFIELD.

St. Mary's Vicarage, Lambeth, Oct. 8th, 1875.

THE SUBSULPHATE OF MERCURY.

THIS "turbith mineral," as it is called in France, is seldom prescribed in this country; but is highly lauded by Dr. Cadet in the *Corresp. Scient. di Roma*, No. 27, 1875, as a remedy against rabies. In the article on the subject, Dr. Cadet alludes to Dr. Edes, of South Carolina, who states that many "distinguished physicians considered the subsulphate of mercury a specific in cases of membranous croup." Italian physicians also use the same salt with much success in pertussis. In fact, the subsulphate is held by some of our brethren in Italy as being highly useful in cholera and the plague.

PURPURA HÆMORRHAGICA.

To the Editor of THE LANCET.

SIR,—The following case is, I think, of sufficient interest for insertion in THE LANCET.

Sarah P——, aged forty-seven, was brought down to death's door by free hæmorrhage at the same time from the tongue, gums, bladder, and bowels. From March 26th to April 6th, 1875, the hæmorrhage was very free from the gums

History.—March 26th, 1874.—Under my care for five weeks for left pneumonia, and had been well a week. The night before last I noticed a swelling, about the size of a pea, on the right edge of the tip of the tongue. She lost blood through the night and next day very freely. On my seeing her it was not bleeding, but had the appearance of a blue extravasation of blood in the substance of the tongue. Her mouth was full of decayed teeth and stumps, and on the left side the gums were bleeding very freely, and she was constantly expectorating florid blood. By her bedside was a basin, containing seven ounces of dark blood mixed with saliva, which she had expectorated during the night and morning. The blood keeps round the gums. She is pale and emaciated; very weak; pulse 100; appetite bad; bowels constipated and irregular; tongue large, moist, and fissured; purpuric spots all over the body, of every shape, most of them of a dark claret colour, some scarlet, and distinctly felt under the skin—they appeared after the swelling in the tongue. Five grains of gallic acid and fifteen minims of dilute sulphuric acid to be taken every four hours.

March 27th.—2.30 P.M.: The patient has taken four doses of the mixture. Gums have bled freely, and blood was still oozing at my visit; a great deal of blood in the urine; pain after micturition. Has taken mutton broth and port wine. Gums to be well rinsed with a lotion of liq. ferri (three drachms to three ounces of water); half-drachm doses of tincture of iron to be taken every two hours, and a draught of half-drachm dose of oil of turpentine. Motions dark-coloured.

28th.—Dr. M. saw her with me. No sleep. Every ten minutes during the night she spat out saliva and blood. Urine of a pale Condy's fluid colour; no sediment. Pulse 130; tongue and mouth coated black from the iron and gallic acid. Had taken two half-drachm doses of turpentine and three or four doses of the tincture of iron, and had rinsed the gums with the iron lotion. She had also taken a dose of ten grains of gallic acid and half a drachm of sulphuric acid every hour. Bowels open; motions dark in colour. To leave off the iron, and rinse the mouth with cold water.—7.30 P.M.: Messenger arrived to say that the hæmorrhage from the gums was still continuing, and that her urine was more high-coloured. To take a pill consisting of three grains of acetate of lead and one grain of opium every two hours, and two drachms of oil of turpentine every six hours.

29th.—2.30 P.M.: Urine the colour of dark claret; expectorated only a little blood from the gums. To take gallic acid, iron, and bark every two hours; to suck ice.

30th.—Bowels opened last night; motions black; passed about a pint of urine, of the colour of damson-juice; also passed a pint last night, very dark; tongue and teeth coated black, and here and there arterial oozing from the gums. Ordered bladder of ice to the hypogastric region. She has taken well of brandy, beef-tea, &c. A mixture of sulphate of iron and liquor ammoniæ.—Evening: Dr. M. saw her. Hæmorrhage from gums still going on; thick sediment of blood in the urine.

31st.—4 P.M.: Still expectorates saliva tinged with blood; passed only three ounces of urine to-day, of a bright scarlet colour, with a clot in it; bowels opened; motions very black. She took a pill of acetate of lead last night. On the left side of the tongue there is a swelling similar to that on the right side, but as large as a field bean, and full of black-looking blood. Pulse 130. Ordered two grains of quinine and five grains of alum every three hours.

April 1st.—Gums bleeding slightly; passed urine twice, still dark.

2nd.—11 A.M.: Passed about four ounces of urine, of a muddy lithatic colour, with a little red blood; frequent and difficult micturition; bowels opened twice; no blood; no uterine hæmorrhage; tongue cleared of its black coating; gums at a couple of spots oozing blood; spots still numerous, but fading.

3rd.—Expectoration from gums scanty; urine lithatic.

4th.—Very pallid; when in sitting posture very faint; slight oozing of blood from gums. To take bark and acid mixture.

5th.—8 P.M.: Very sick; expectorating a quantity of saliva slightly tinged with blood; passed about two hours ago two ounces of lithatic urine, no blood, but had also passed about four ounces of very dark-coloured urine; tongue clean; pulse 130.

7th.—No blood from gums or in urine; spots fading.

11th.—Going on favourably; spots dull on arms, brighter on chest. From this date the patient got quite well. Yours &c.,

Tenbury, October, 1875. F. H. THOMPSON, Surgeon.

ANTI-VACCINATION POSTAL CARDS.

To the Editor of THE LANCET.

SIR,—The announcement of the birth of one's child in *The Times* would seem to be attended by an infliction through the post of rather a formidable character, if my experience is similar to that of others. First came printed lists, with illustrations of various articles of baby linen; then arrived trade lists, with dozens of testimonials from medical men, of bottled stout, "particularly recommended by the faculty for nursing purposes"; thirdly, photographs from various parts of the country of the birth column of the "leading journal," containing the interesting notification itself, with a request for twelve stamps; fourthly, postal cards from the Anti-Vaccination League, full of what may be politely called errors, &c. &c. The last named I beg to enclose for your inspection, in order that you may know the means that are employed by the few misguided men composing that body for the dissemination of their pernicious crotchets amongst the ignorant.

Yours truly,

October, 1875. A MUCH-ENDURING PARENT.

Resolute Inaction.

The "Local Board" of Nantwich has formally and deliberately resolved not to move in the matter of sewage reform, because the cost of any change would be considerable, and the local nuisance is not great. Only a hundred houses discharge their sewage directly into the river Weaver, and the landowners (!) are not known to suffer any serious injury therefrom. The spectacle of a "Board" thus defying law and prudence would be amusing if the consequences were not likely to be mischievous. We shall hope to hear that some form of compulsion, more formidable than the injunction with which the Local Board of Nantwich has been playing for the last twelve months, has been discovered and applied with an earnestness equal to the obstruction.

"Public Conveniences."

To the Editor of The Lancet.

Sir,—I observe you have recently with just cause commented upon the general filthiness of public conveniences. Whilst the attention of the public is yet directed to this subject, I venture to suggest to you what would, in my opinion, be a further step in the right direction. It is generally felt as a great want the impossibility of discovering the whereabouts of a post-office or a urinal. In Edinburgh this want has been recognised by the authorities, and these places are now distinguished by *coloured lamps.* I trust that in the interest of the public you will, through the medium of your columns, urge upon the proper authorities the adoption of some such plan.

I am, Sir, your obedient servant,
Philpot-lane, City, Oct. 5th, 1875. William Beattie.

Insurance against Sickness.

To the Editor of The Lancet.

Sir,—It is strange that amongst all the Insurance Societies there is not one, so far as I can find, that issue "sickness policies." There are many Benefit Societies, but these are confined to the artisan and labouring class. The advantages of a Society of this nature to the members of the medical profession cannot be estimated, as, for instance, to younger medical men, who, like myself and many others, depend solely on their own exertions for their independence. The letter of Dr. Jas. O. M'Creery in your impression of last week leads me to hope that the subject will not be lost sight of.

I am, Sir, yours faithfully,
Clapham, Oct. 13th, 1875. J. De Burgh Griffith.

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from—Prof. Humphry, Cambridge; Dr. Wilks, London; Mr. Holmes, London; Dr. Curnow, London; Surgeon-General Maclean; Mr. Wright, Liverpool; Dr. Gill, Clapham; Mr. Hudson, South Cave; Mr. Moore, London; Mr. Madden, London; Mr. Roberts, Keighley; Mr. Thompson, Tenbury; Mr. Smith, Dublin; Dr. Fort, Paris; Dr. Dougall, Glasgow; Mr. Ireland, Linton; Dr. Stainthorpe, Hexham; Mr. Lund, Manchester; Dr. Parsons, Dover; Mr. Williams, London; Dr. Peters, New York; Mr. Harrison, Liverpool; Dr. Bodine, Trenton, U.S.A.; Mr. Mulvany, R.N.; Dr. Dudfield, Kensington; Mr. Sewill, London; Mr. Brown, Dorchester; Mr. MacGregor, London; Mr. Collins, Dover; Dr. Lawrence, Bayswater; Dr. Adamson, Hetton-le-Hole; Mr. Rendle, London; Mr. Colbeck, Dover; Dr. Dickson, London; Mr. Bromfield, London; Mr. Loudon, London; Dr. Speedy, Dublin; Dr. Roper, London; Mr. Ingpen, London; Dr. Clark, Walsall; Mr. Moreton, Leamington; Mr. Skinner, Worksop; Dr. Griffiths, Rhyl; Dr. Lister, Ashton; Mr. Robinson, Folkestone; Mr. Hooper, London; Mr. Force, Exeter; Mr. Gray, Edinburgh; Dr. Fox, Brighton; Dr. Evans, Cardiff; Dr. Cole, Bath; Dr. Cripps, Cirencester; Mr. Irving, Huddersfield; Dr. Edis, London; Mr. Meadows, Bradford; Mr. Searle, Brixham; Mr. De Burgh Griffith, Clapham; The Secretary of the Medical Society of London; Culpho; S.; Rufus; Abyla; Registrar-General, Edinburgh; The Secretary of the Harveian Society; Surgeon, Thaxted; The Secretary of the Improved Industrial Dwellings Company; A. B., Dorrington; M. B., Glasgow; A. B., Leicester; The Secretary of the Pathological Society; A Subscriber; Mataro; Enbuirer; M.R.C.S.; Constant Reader; A Student; Beta; &c. &c.

Letters, *each with enclosure*, are also acknowledged from—Dr. Wollaston, Lyme Regis Mr. Pursey, Liverpool; Mr. Flint, London; Mr. Royds, Rochdale; Mr. Leeds, Brenchley; Mr. Brown, Stockton-on-Tees; Messrs. Hartill and Co., Willenhall; Mr. White, London; Mr. Hilliard, Birmingham; Mr. Jones, Pendelton; Dr. Nihill, Tulla; Mr. Whitbourne, Topsham; Mr. Buller, South Brent; Dr. Sloane, Leicester; Mr. Thorpe, Walsall; Mr. Allen, Ivy Bridge; Mr. Walters, Edinburgh; Mr. Tilsley, Burslem; Mr. Girdlestone, Andover; Mr. Drury, Harleston; Dr. Ramsay, London; Dr. Ginders, Normanton; Dr. Hodgson, Preston; Mr. Lloyd, Lambeth; Mr. Neill, Bangor; Messrs. Maclachlan and Co., Edinburgh; Mr. Buck, Leicester; A. Z., Amersham; Theta, Walsall; L. C. B., York; Medicus, Bath; L. M. N.; A. H. S., Eltham; Omega, Peterborough; M. D., London; Sentry, London; Medicus, Halifax; Alpha, Birmingham; Medicus, Ripley; B. B. J., Durham; W. T., Frome; A. B., Manchester; Principal, York; A. F.

Newcastle Chronicle, Cork Constitution, Western Morning News, Record, Local Government Chronicle, East London Observer, Metropolitan, Surrey Advertiser, Hackney and Kingsland Gazette, Huddersfield Chronicle, Sussex Daily News, Manchester Guardian, Birmingham Morning News, Leeds Mercury, Wrexham Guardian, Hull News, Liverpool Mercury, Dover Telegraph, Welshman, Colchester Mercury, and *Daily Bristol Times* have been received.

Medical Diary for the ensuing Week.

Monday, Oct. 18.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10½ a.m. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ p.m. each day, and at the same hour.

St. Mark's Hospital.—Operations, 9 a.m. and 2 p.m.

Metropolitan Free Hospital.—Operations, 2 p.m.

Medical Society of London.—8 p.m. Opening Meeting of the Session.—Dr. Routh, "On Hyperpyrexia viewed especially in its Surgical Aspect." Dr. Thorowgood, "On a Case of Acute Pneumonia."

Tuesday, Oct. 19.

Guy's Hospital.—Operations, 1½ p.m., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 p.m.

National Orthopædic Hospital.—Operations, 2 p.m.

West London Hospital.—Operations, 3 p.m.

Pathological Society of London.—8½ p.m. The following Specimens will be exhibited:—Hydatid Cyst of the Liver which burst into the Lung; Fractured Bones of Gorilla; Rickets in Young Pheasants; Supra-renal Capsular Disease; Ulcer of Stomach; Calculi of Cystic Oxide; Epithelioma of Tongue and Jaw; Subarachnoid Hæmorrhage of Cord; Thrombosis of Internal Carotids; Uncommon form of Carcinoma of Breast; Tumour of Anterior Cerebral Artery, &c.; Carcinoma Lipomatosum of Kidney; Tubercle of Pancreas; &c. &c.

Wednesday, Oct. 20.

Middlesex Hospital.—Operations, 1 p.m.

St. Mary's Hospital.—Operations, 1¼ p.m.

St. Bartholomew's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

St. Thomas's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

King's College Hospital.—Operations, 2 p.m., and on Saturday at 1½ p.m.

Great Northern Hospital.—Operations, 2 p.m.

University College Hospital.—Operations, 2 p.m., and on Saturday at the same hour.

London Hospital.—Operations, 2 p.m.

Samaritan Free Hospital for Women and Children.—Operations, 2½ p.m.

Thursday, Oct. 21.

St. George's Hospital.—Operations, 1 p.m.

Royal Orthopædic Hospital.—Operations, 2 p.m.

Central London Ophthalmic Hospital.—Operations, 2 p.m., and on Friday at the same hour.

Friday, Oct. 22.

St. George's Hospital.—Ophthalmic Operations, 1¼ p.m.

Royal South London Ophthalmic Hospital.—Operations, 2 p.m.

Clinical Society of London.—8½ p.m. — Adjourned Discussion on Mr. Callender's Case of "Treatment of Wounds with Salicylic Acid," and Mr. Pick's Case of "Treatment of Wound of Knee-joint with Carbolic Acid."—Mr. T. Holmes, "On a Case of Ligature of Femoral Artery with Carbolised Catgut." — Mr. Haward, "On a Case of Lymphadenoma."—Dr. Murchison, "On a Case of Acute Cancer of the Liver, with Pyrexia, in a Man aged twenty-four"; "On a Case of Abdominal (Hepatic?) Abscess without Elevation of Temperature"

Quekett Microscopical Club.—8 p.m.

Saturday, Oct. 23.

Royal Free Hospital.—Operations, 2 p.m.

Charing-cross Hospital.—Operations, 2 p.m.

TERMS FOR ADVERTISING IN THE LANCET.

A Clinical Lecture
ON
THE PULSE: ITS DIAGNOSTIC, PROGNOSTIC, AND THERAPEUTIC INDICATIONS.

Being Lecture V. delivered at St. Mary's Hospital in the Summer Session of 1875,

BY W. H. BROADBENT, M.D., F.R.C.P.,
PHYSICIAN TO THE HOSPITAL.

(*Concluded from p.* 550.)

FROM what I have previously said you will understand the signs by which we recognise a pulse of high tension. I will, however, once more briefly recapitulate them. But first let me describe the normal pulse. It is of course of average frequency, regular as to time and equable as to strength, and it will be compressible by moderate force, not shooting suddenly under the fingers nor lingering long on the touch. The artery ought not to be easily distinguishable in the intervals of pulsation; it should present no irregularities when the skin is rubbed along its course; and especially it should not roll under the fingers like a solid cord, or be traceable far up the forearm. The pulsations ought not to be visible, or at any rate not conspicuous. When there is high tension, the artery, usually rather small, but sometimes large, is hard and cord-like; it can be rolled under the finger, and is easily traced in its course up the forearm, where it feels like another tendon lying amidst those in front of the wrist. It reminds one, as I have often said when pointing out these features in the wards, of the vas deferens.

When the fingers are first lightly placed upon the vessel, the pulsation detected is inconsiderable, and such a pulse on superficial examination is often set down as weak, but let pressure be applied with a view to its extinction, and it is found to be compressible only on the employment of great force. The apparently weak and really slight pulsatile movement is due to the fact that the artery remains full during the diastole of the heart, and is not flattened by the degree of pressure ordinarily applied; not being flattened, the change of shape produced by the increased pressure of the systole is necessarily inconsiderable. The remaining feature of high arterial tension is that, in consequence of the resistance which has to be overcome by the heart, its contraction is prolonged. The expansion of the artery, therefore, is prolonged, and does not quickly leave the finger, making the pulse long. Briefly, then, the pulse is *small, long,* and *hard.* And this is the general character of the high-tension pulse met with, but there are important exceptions and qualifications which must be mentioned, though they cannot be fully considered here. For instance, the artery is sometimes large, very large; the pulse must then be called large, hard, and long, but the pulsation is not large and free for the reason given. Again, when the action of the heart is weak the pulse may appear to be short.

The condition of tension is often associated with tough and thickened arteries, especially in kidney disease, and is often mistaken for mere arterial degeneration; but it frequently occurs as a temporary condition in perfectly normal vessels. The conditions giving rise to high tension may be classified and enumerated as follows:—

1. Degeneration of vessels. Of this there are two kinds. In one the artery is usually large, but sometimes small when associated with a weak heart, and as the finger is run along it, it is found to be bulging at different points, and feels thickened. In the other form the vessel is calcareous, and feels like a string of beads; in this form the artery is not necessarily large. I do not think one is simply an advanced stage of the other.

2. Kidney disease; pregnancy.

3. Gout; suppressed gout, or retained nitrogenised waste; lead-poisoning.

4. Affections of the nervous system.

Besides these, there are various unclassified cases, in which I cannot assign a definite reason for the existence of high tension.

1. *Degeneration of the vessels.* — This frequently results from renal and gouty disease, and it is difficult to draw the line between the tension of these conditions and degeneration.

Arterial tension is produced by obstruction in the capillaries and arterioles to the passage of blood laden with excretory matters, nitrogenised waste, or imperfectly oxidised material present in kidney disease or gout. If this condition of tension be long continued, it matters not from what cause, it will damage the arterial system; it will produce hypertrophy of the heart; the constant strain will affect the aorta and produce endarteritis; it will show its effect on the arterioles by their thickening and the hypertrophy of the muscular coat, and ultimately by degeneration.

But arteriole degeneration may be otherwise induced; it cannot, at least, always be traced to tension, of which it becomes a cause. Whether as cause or consequence, we usually have to deal with degeneration in association with tension, and the recognition of degeneration must be effected partly by the state of the vessel, but also by other general considerations. When the artery feels like a string of beads under the skin, the case is clear; but in the form first mentioned, in which there is no calcareous change, with the indications of tension, and the large size of the vessel, the inequalities detected as the finger is carried along its length, a sensation of resistance, stiffness, or toughness are the signs presented by the vessel. Together with these we consider the age, appearance, history, general condition of the patient, the state of the temporal arteries, cornea, conjunctiva, skin, &c.

When a diagnosis of advanced arterial degeneration is formed the prognosis is of course very serious, and all we can do by treatment is to obviate the evil consequences more or less imminent, and postpone as long as possible the inevitable result. The evils threatened vary in different cases. One of these is apoplexy. When the heart retains its vigour and continues to act powerfully while the flow of blood through the capillaries is obstructed, the liability of degenerate vessels to burst under the high pressure at which the circulation is maintained is obvious. On the other hand, if the heart shares in the structural changes and is weak, the languid movement of the blood in diseased vessels is likely to give rise to thrombosis and cerebral softening. When there is kidney disease, uræmia is of course a contingency to be feared. But the prognosis of an attack of acute disease of any kind is made more serious by the existence of arterial degeneration.

I propose to illustrate these statements by cases which have been under my care, and more especially by cases in which the arterial condition has actually furnished a basis for prognosis subsequently verified by the result. Every day we see cases in which we reason backwards and explain the occurrence of apoplexy, &c., which we are called upon to treat, by the state of the vessels; but I am anxious to show you that we can reason forwards and predict, and if we can predict we can sometimes prevent.

The first case is that of a Scotchman, aged fifty-two, who came under observation in May, 1873, with the following history of himself. Five months previously, while apparently in good health, although he had felt conscious for some months that he was unequal to business at times, and his hands often became blue and cold, he was taken with a sudden giddiness; he did not fall, but was unconscious from fifteen to twenty seconds. On recovery he felt weak in his arms and legs. He had never been well since, and had always been under treatment. For some time he was at an hydropathic establishment, where he tried the water cure. His was almost the worst case possible for such treatment, and he became worse. He was treated also, at one time, with a "bitter syrup," which made him insensible; this was probably syrup of chloral hydrate; he was none the better for it. He did not look his age, was well fleshed and had good colour in his face, but was a little sallow and puffy under the eyes. His expression was dull, and he had a look of want of energy. There was somewhat of a renal appearance about him, but there was no albumen in his urine; its specific gravity was 1018, and it was of good colour; at one time there was a faint turbidity by heat, which was not quite removed by acid. At times he felt giddy. His arms were weak and his hands cold and purple. His walk was weak, but he was able to stand with his eyes shut, and on either leg, alone. His speech was slow but distinct, his voice weak and monotonous, and he could not write well. He frequently had hesitation in swallowing liquids, feeling unable to do so; but there was no return by the nose, and no choking. He soon became confused when talking or thinking, and made many mistakes. He always fell asleep after dinner, and slept heavily at night; he had also become apathetic, whereas formerly he was energetic.

Here was a case of damage to the medulla oblongata. The pulse gave the key to its character; it was long and hard, and the artery presented inequalities to the touch; the temporals also, especially the left, were tortuous and hard. The heart sounds were of a tic-tac character—that is, equidistant and similar—and were loud. The aortic second sound especially was loud and booming and was heard over a large area. The aorta itself was dilated; it could be felt above the sternum; and there was dulness across the upper sternum.

His vision was not good. The pupils were small, and there was slight arcus senilis at the upper part of the cornea. The ophthalmoscopic examination was not satisfactory, only an imperfect view of the fundus being obtainable in the left eye; bright white spots were seen near the yellow spot, and the right disc was red and ill-defined.

My diagnosis was, disease about the medulla, probably a limited hæmorrhage. The prognosis I gave from the state of his vessels was bad; some improvement might be obtained, but sudden death from apoplexy was to be anticipated. I was unable to find a cause for the bad state of his arteries, and this perhaps made the case of a more serious nature. The treatment I adopted was an aperient mercurial pill, to reduce the arterial tension, iodide and citrate of potash, phosphorus, and cod-liver oil. Unmistakable, indeed remarkable, improvement took place at first, but after one or two warnings, two months after I first saw him he had his attack of apoplexy, which, from the symptoms, was apparently hæmorrhage into the pons and medulla, and died. Unfortunately, I was away from town at the time and no post-mortem was obtained.

Another case of extreme interest is that of a gentleman, aged sixty-two, whom I was called to see in June, 1873. He was suffering from a well-pronounced but mild attack of gout; but his family were uneasy about him, for lately he had been getting paler, feebler, apathetic, easily fatigued, disinclined for exertion, and, indeed, incapable of it, for he soon became out of breath. The gout, in this case, was comparatively unimportant; it was its results that were dangerous. He was a country gentleman; but his habits were not active, as is usual with his class, though his living was of the usual generous description, and he took beer of his own brewing, which was very good, sherry, and port daily. It was not, therefore, to be wondered at that he had had gout for seven years, and with it the frequent accompaniment of eczema and other gouty troubles.

He had a terrible family history, as I learnt later. As I sat on Sunday in the family pew of the village church I was struck with the history recorded on the long series of his ancestral monuments. They were a long-lived race, averaging from eighty to ninety years for many generations; but his father died at seventy-three or seventy-four, and already one younger brother had died of Bright's disease and apoplexy, and he had another the subject of renal disease and paralysed.

His face was rather sallow and pale, with faded red on his cheeks. He had a well-marked arcus senilis all round the cornea. His pulse, which was rather frequent, was long and hard. He had slight reduplication of the first heart-sound at the apex, and a loud second sound at the base. His urine was of sp. gr. 1013, pale, not quite clear, and it had a trace of albumen, which came and went. Here was a typical case of so-called arterio-capillary fibrosis, with contracted and granular kidneys, due to true gout. He had high tension, damaging his arteries; and this or the same state of blood which had given rise to the tension had affected his kidneys. His condition fluctuated with the variations in the arterial tension. This, therefore, indicated the treatment, which was directed to reducing it by every means at our disposal. I ordered him mercurial aperients, though I was aware of his kidney disease, saline purgatives, iodide of potassium, citrate of ammonia, and then tincture of iron. His diet was also strictly regulated; it was made to consist largely of milk, eggs, and fish. He was directed to stop his wine and beer, and to take whisky and Apollinaris water. This was followed by wonderful improvement, and he went for change to the seaside. While there he had an escape for his life from constipation, which he neglected. He came back, however, much improved. All went well with him till the spring of 1874, when the election business, with its attendant exertion, exposure, and excitement proved too much for him, and he knocked up under it. He now began to have severe nocturnal dyspnœa, the attacks coming on at 2 or 3 A.M. There was a wheezing sound, but air entered the lungs quite freely, and the dyspnœa was, in fact, cardiac. There was general arterial spasm, the pulse being even smaller, longer, and harder than usual, and the reduplication of the first heart-sound more marked; the left ventricle was, apparently, unable to force on through the arteries an adequate amount of blood, and, accordingly, too little reached the right ventricle and lungs. Possibly the attacks were in part uræmic. Mercurial and saline aperients were again given, and were followed by great relief. A fortnight later he had sudden loss of sight, which came on while stooping. Before I saw him this had improved, and he saw better; but there remained a peculiar limitation of the field of vision—all appeared dark except what was immediately before him. The ophthalmoscopic examination showed the retinal arteries to be so small as to be scarcely visible, and there was œdema around the disc. The high tension was now again remarkable. The sight gradually improved; but improvement in the general health was very slow. He went to the seaside in August. Here he again neglected his bowels, which became constipated. This brought on a profuse attack of hæmorrhage from the bowel, by which he was completely prostrated; but he once more improved in every respect. In February of this year he had again severe dyspnœa, with pulmonary congestion, and finally came the attack of apoplexy which I had so long feared.

Arterial degeneration, chronic renal disease, and arterial tension are often so combined in the same case that I have difficulty in deciding under which head to describe some of those I wish to relate to you. It was so in the last case, but I considered the arterial condition the one which most threatened danger, and so I take it to have been in the following, in which good results, at one time unhoped for, attended the intelligent and persevering application of principles of treatment indicated by the pulse, by my friend Dr. Kilner Clarke, of Huddersfield.

The patient, a gentleman aged fifty-six, engaged in commerce, had fair health till twelve months before I saw him, which was in March, 1874. He was at this time suddenly seized with great giddiness one morning, and for the remainder of the day was continually vomiting. This was set down to biliousness, but he had never been free from giddiness since; was nervous, and started readily; was soon tired; and his memory was impaired. A slight difference was observable in the muscular markings of the two sides of the face, these being smoothed out a little on the left. The temporal arteries stood out; the pulse was rather small, very hard and long; the arterial tension was extreme, and a short systolic puff was heard over the aorta. Urine of sherry colour; sp. gr. 1009; no albumen. Ophthalmoscopic signs negative.

Dr. Clarke had recognised these facts, and ordered appropriate treatment; but a physician consulted in London advised it to be left off. Soon afterwards I saw the patient, and the line of treatment was resumed: one grain of mercury pill, one-third of a grain of extract of colchicum, and two and a half grains of compound colocynth pill, being given twice a week; and three grains of iodide of potassium, ten grains of bicarbonate of potash, five minims of colchicum wine, with spirit of ammonia and tincture of oranges, three times a day. There was improvement, but the patient had work and anxieties in his business for which he was unfit. In December he had unilateral convulsive attacks, and albumen appeared in the urine. When I saw him in January his walk was feeble, his speech indistinct, and his aspect that of cerebral mischief. Still his general condition was much better, his arteries were softer, his tissues more healthy, and his colour fresher and less sallow; so that, with cessation of business worries, now absolutely necessary, I was not without hope of improvement. The patient remained entirely under Dr. Clarke's management; and when

I last heard of him, in June, he had shaken off the cerebral symptoms, and was so much better in every way that he was returning to business, from which he had definitively retired.

I have now under observation a lady, the wife of a medical man, in whom I predicted cerebral hæmorrhage, and in whom also it has occurred. She suffered from violent palpitation, faintness, and feeling of lowness, for relief from which she had resorted to stimulants. She had also become weak and liable to attacks of vertigo. From this and from timidity she had almost entirely given up out-door walking. I never met with a case of such extreme high tension. The pulse-rate was habitually nearly 120, the arteries everywhere prominent and tense. She had a rather bloated, red face, which was still more disfigured by acne; and her aspect was that of extreme plethora. I obtained by much urging a modification of her diet, but I could not prevent recourse to stimulants, which were not, however, taken to excess. I only saw her twice, early in the year, but felt certain of the condition which threatened her, and gave a prognosis of apoplexy. In May she had her first distinct warning, which came in the shape of hæmorrhage into the left retina, with loss of sight. In June she had more severe and alarming symptoms, a meningeal hæmorrhage having apparently occurred. On the night of the 6th she became restless and irrational in her talk, and then a severe attack of convulsions came on; she had altogether four attacks of convulsions within twelve hours, which were followed by prolonged loss of consciousness, and when recovering from this she was in a state of extreme excitement, with delirium and delusions and complete loss of memory; she became also extremely obstinate and violent.*

But, besides furnishing a basis for prognosis, arterial degeneration often explains to us a long train of miserable nervous symptoms coming on late in life—loss of energy, depression of spirits, a feeling of confusion in the head, sleeplessness, transitory loss of consciousness. I have in mind the case of a lady for some time under my care, formerly energetic, active, full of spirits, now prostrated or confused by the slightest exertion, bodily or mental, scarcely able to walk, or to write a letter, or to command her attention, sleepless, and persecuted by a constant pain in the back of the head. She is relieved by the very means which her weak state would seem to contra-indicate.

You have seen also in two cases, one still in the hospital, the other only just discharged, how convalescence from slight illness has been protracted almost indefinitely for no assignable reason except that the arteries were degenerated. In one, however, the heart was weak, and till restored by prolonged rest in bed its systole gave neither impulse nor first sound. Both the patients were women, who, nearly up to the time of admission, had been able to attend to their duties, and both came in for subacute rheumatism. The first, a monthly nurse, aged fifty-seven, had a slight attack of pneumonia a few days after her admission, but this did not at all account for her extreme weakness and slowness in recovery. It was more than three months before she could stand, and when she left the hospital, at the end of four months, she could only just walk the length of a small ward. The arteries were small, irregular, resistant, certainly degenerated, perhaps on the way to calcareous change; and this, I think, explained the difficulty attending the re-establishment of the nutrition and restoration of strength. The case of the other patient was very similar, and I need not give the particulars.

When advanced calcareous degeneration of the small arteries exists it can scarcely escape attention, even on the most superficial examination. The radial feels, as I have said more than once, like a string of small beads when the fingers are carried with the skin along its length. All I need do is to remind you that with the vessels in this condition a very slight ailment may prove fatal. I have had no marked instance in the wards lately, and to read you notes of cases I have had under observation formerly would simply be to give you accounts of the complications by which the patients were carried off. In one the chain of events was bronchitis, œdema of feet gradually progressing to general dropsy, failure of right heart with enlarged liver, and albuminuria. In another, attacks of giddiness, loss of energy and memory, indistinct and slow articulation, later a gradual impairment of the faculties, occasional escape of urine and fæces in bed or into clothes, and ultimately the entire train of symptoms attending cerebral softening.

I propose to take up this subject again on another occasion, for I find I have not time to complete it to-day. It is not merely in forming prognosis that a careful study of the indications furnished by the pulse is useful, but also in treatment, and of this I hope to give illustrations.

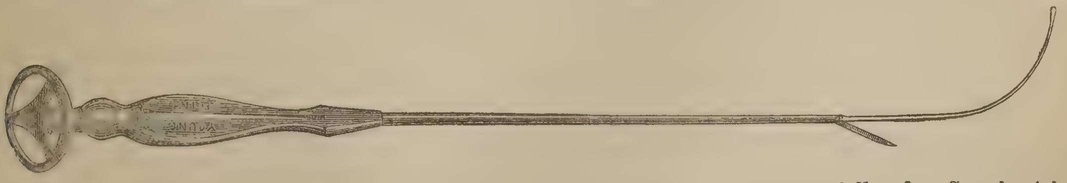
ON A

NEW URETHROTOME FOR INTERNAL URETHROTOMY.

By PATRICK HERON WATSON, M.D., F.R.S.E., &c.,
SENIOR SURGEON TO THE ROYAL INFIRMARY, EDINBURGH.

I have no wish to enter into any consideration at present of the advantage of one method of treating stricture of the urethra as compared with another. I believe that dilatation, divulsion, external and internal urethrotomy, have each their separate sphere, and form an efficient armoury, from which a skilled surgeon will, according to circumstances, select his appropriate weapon. I wish at present merely to direct attention to a new instrument which two years ago I had constructed for the internal division of strictures of the urethra. It has seemed to me much more satisfactory than any other form of instrument, intended to effect internal urethrotomy, with which I am acquainted.

The original instrument I had constructed for me in Paris under the direction of my former resident surgeon, Mr. C. W. Macgillivray, by Luer of Paris, but as its size was too large for the treatment of very tight strictures, I had a modified instrument, upon the same principle, constructed by Mr. Young of this city. From the accompanying woodcut it will be seen to consist essentially of a Syme's stricture staff, from which a tenotomy blade is made to protrude at an angle on turning from left to right a wheel fixed at the proximal extremity of the instrument. This instrument is probe-pointed at the distal extremity, and the size of a No. 10 or 12 at the haft. The instrument gradually increases for four inches from the fine probe-pointed extremity, up to the size of a No. 2 bougie. Here it abruptly enlarges to the size of a No. 12. At this point, where the thick and thin portions of the instrument are continuous, a tenotomy knife-blade, concealed in a groove in the slender part of the shaft, is so pivoted that it can be projected at an angle with the commencement of the thick portion of the staff. The degree



---

* The treatment consisted chiefly in free purgation. Venesection was to have been practised had convulsions again come on. Bromide of ammonium was given for a short time. A farinaceous, milk, and fish diet was prescribed, and stimulants forbidden. When this lecture was delivered, the mental powers appeared to be so much shaken that anything like complete recovery was scarcely hoped for, especially as improvement of intellect did not at all keep pace with the improvement in the patient's general condition. To my astonishment, the arterial tension was gradually reduced, the pulse became perfectly soft and natural, without being weak, and the rate came down to 72. The arterial degeneration I had diagnosed did not, in fact, exist; and I think the tension, which was quite the most remarkable I ever met with, was due to the frequent and powerful action of the heart, which forced blood into the arterial system faster than it could escape by the capillaries, except under great pressure. For some weeks the behaviour was peculiar and memory all but lost. Now, however (July 12th), except that the memory is still weak, the patient is well.

of angular projection of the knife is determined by the number of turns given to the screw attached to the handle of the instrument, and this degree of protrusion is marked by an indicator on the shaft. For the purpose of cleansing the instrument after use, the blade can be screwed out to a right angle to the shaft; but in use, when dividing a stricture, no protrusion beyond an angle of 45° is required. The instrument in all its parts, except the blade, is nickelised to prevent rusting.

When employed the instrument is introduced with the blade enclosed in its groove. When the pointed extremity has been insinuated through the strictured part of the canal, it glides smoothly onwards towards the bladder, till the anterior extremity of the stricture arrests the progress of the thick portion of the staff. The anterior extremity of the stricture is thus determined with absolute precision, and as few strictures exceed an inch and a half in length, the blade is sufficiently long to secure the division of the stricture with one movement of withdrawal of the whole instrument. When once the instrument has been lodged in close contact with the stricture, the screw in the handle is turned so as to secure a protrusion of the blade to an angle of 30°, the whole instrument is then drawn forward as if to withdraw it from the canal. When this is at first attempted it is felt to be firmly held, then the tissues yield. When the instrument has been withdrawn about two inches from the urethra, the screw is inverted, causing the blade to retreat completely into its groove, and the passage of the whole instrument onward towards the bladder is once more attempted. In most instances this is found unopposed. And if it be so, the urethrotome is withdrawn, and a full-sized catheter passed to empty the bladder. Should the passage onwards of the thick portion of the instrument be opposed, either another stricture or some portion of the same stricture is shown to be undivided. A reprotrusion of the blade, and repetition of the movement of withdrawal, will secure the division of this obstruction, and similarly of any other constriction which may still oppose the passage of the full-sized portion of the stem of the instrument.

I have never encountered any troublesome hæmorrhage in the use of this instrument, while by means of it the extent of tissue divided has always been completely under control.

The woodcut shows very well the appearance of the instrument with the blade protruded at an angle of about 20 deg.

The advantages which this instrument has seemed to me to present are:—1. It determines accurately the anterior aspect of the stricture, while the shaft has been insinuated through the contraction. 2. It divides the stricture from behind forwards. 3. It enables the operator, by the abrupt shoulder on the shaft, to determine whether, by the use of the cutting apparatus, the stricture has been completely or only partially divided, and admits of his completing the division if need be, without any change of instrument, by merely repeating the same steps of operative procedure, as in the first instance. 4. It limits the section of the urethra to the part or parts which are actually contracted, and does not "promenade" the whole canal. 5. Its use is attended by remarkably little pain or bleeding.

As the arrangement of the wheel and screw admits of no yielding of the blade, even in fibrous, cartilaginous, or resilient structures, in which cases I have chiefly employed it, the section of tissue is effected with absolute certainty, the gradual angle or wedge-forming position of the knife to the stem of the instrument securing that the cutting edge will act against all tissues with which it is brought in contact as the instrument is withdrawn. Neither have I found any difficulty in retiring the blade within its groove when the section is complete, the fitting of the parts securing them against the possible interposition of any portion of the surfaces of the divided soft tissues.

For strictures situated in the anterior portion of the urethra, an instrument constructed precisely in the same manner, but shorter and quite straight, is made. I find myself, however, that the ordinary curved instrument is quite sufficient for every purpose.

The cutting-blade has its edge turned towards the floor of the urethra, but it may be constructed to act upwards if so desired, or to work with a double-edged knife, both upwards and downwards. I prefer myself that the incision should be made only in one direction, and that downwards or towards the floor of the canal.

Edinburgh

CASE OF MEDIASTINAL TUMOUR.

By THOMAS COLE, M.D., M.R.C.P.,
PHYSICIAN TO THE ROYAL UNITED HOSPITAL, BATH.

I am indebted to my friend and house-physician, Mr. Field, for most of the notes of the following case.

William I——, aged fourteen, a traveller, was admitted into the Royal United Hospital, Bath, on Aug. 9th, 1875.

History.—With the exception of being in a London hospital some time since, for some weeks, he gives no account of illness till three weeks ago. He then had an eruption on the right lip, with a barking cough. A week afterwards he ran, in the early morning, after a stray horse, and fell down all bathed in perspiration. A week ago he was wrestling with a playmate, when he suddenly became breathless, but felt no pain. Since that time the breathing has been so difficult that he could not lie down in bed; last night he could not go to bed at all. He has been very thirsty for three weeks, with a bad appetite and confined bowels.

Present condition.—Respiration most painfully laboured, not much quickened; slight cough; tongue furred; no marked blueness of face; heart apparently healthy. Dulness at right lung-apex anteriorly, and at posterior left base; at the latter spot tubular breathing; on both sides anteriorly, except at the extreme left apex, the breathing is very indistinct, very little air seeming to enter the chest. Expiration prolonged everywhere; no crepitation nor rhonchus. Liver two inches below the costal margin; spleen not enlarged. Temperature at 9 P.M. 99° Fahr.; respiration 32; pulse 134. Ordered, three grains of carbonate of ammonia, half a drachm of compound camphor tincture, and ten minims of tincture of squill, to an ounce of water, every four hours.

Aug. 10th.—Temperature 98·6°; respiration 33; pulse 122, small and weak. Passed a dreadful night, wanting to get in and out of bed; orthopnœa; face bedewed with perspiration; lips somewhat blue; external jugulars swollen, the left more than the right; superficial veins on the right side of the chest prominent and enlarged; tenderness over this part; much heaving of the chest on inspiration; a few small cervical glands enlarged; total dulness in the right anterior chest, including the sternal region; but little movement; nearly the same on the left side; fremitus diminished, except at the lower right half; vocal vibration diminished. Right chest posteriorly: a tympanitic note everywhere except at a point behind the infra-axillary region, where there is dulness; loud blowing breathing all over. Left chest posteriorly: hyper-resonant superiorly; dull, with a tympanitic modification, below; vocal fremitus much diminished below, somewhat increased above. Tubular breathing heard generally, with a little small crepitation. The diagnosis now arrived at was, that the patient was suffering from a tumour in the anterior mediastinum, malignant in its nature, and probably of a lymphadenomatous character. Evening temperature 99·6°; respiration 36; pulse 136; urine acid, sp. gr. 1027, loaded with pink and white lithates, no albumen.

11th.—Morning temperature 98·4°; respiration 30; pulse 124; very bad night; constant orthopnœa; temperature, according to the nurse, was 103° at 8 A.M.; tongue much coated; sweating profusely; takes scarcely any food; no excess of white blood-cells.—Evening: Temperature 100·4°, respiration 40, pulse 142. Ordered ten grains of chloral.

12th.—Temperature 98·6°, respiration 36, pulse 140; slept about two hours after a second dose of chloral; no improvement; there was evidence of a larger accumulation of fluid in the pleural cavities.—Evening: Temperature 99·4°, respiration 40, pulse 146. Death somewhat suddenly ended the poor lad's sufferings the same night.

Post-mortem examination.—On opening the chest a large quantity of serous fluid escaped from both pleural cavities; on the right side it was confined to the anterior two-thirds of the chest by old firm adhesions, and the lung was bound down in a carnified state at the back; on the left side the carnified lung floated freely in the fluid. The lungs were free from growth, except a few white grains on the pleural surface. Beneath the costal pleura, and situated over the ribs, were masses of new growth; these were at the posterior part of the chest, and quite removed from the main mass which filled the anterior mediastinum. Microscopically, they consisted of lymphoid tissue. A very large and somewhat irregular mass filled the anterior mediastinum; it was adherent to the sternum, ribs, and diaphragm, and encroached a little more into the left chest than the right. The trachea and œsophagus ran down behind it, without being constricted. The tumour was firmly and intimately united with the outer layer of the pericardium. This contained a quantity of dark bloody-looking fluid. There was no growth from its serous surface. The heart, which was pushed somewhat backwards, had a few small pieces of hard white substance on its surface, which consisted of fat and lymphoid tissue. The liver and spleen were healthy, but the kidneys contained several large round masses of white growth. No other glands beyond the mediastinal were implicated. The mediastinal tumour presented all the microscopical characters of a lympho-sarcoma.

Bath.

NOTES OF SIXTEEN CASES OF ABORTION.

By JOHN DOUGALL, M.D. Glasgow.

The abridged particulars of the following cases are submitted, not to illustrate any novelty in treatment, but from their variety and clinical interest.

Case 1.—Mrs. D——, aged thirty-six, in fifth month, second abortion, fifth pregnancy, got a kick on the abdomen from her boy in bed. Two days after had slight oozing of blood from vagina, with pelvic and lumbar pains. On third day both increased. Os uteri was somewhat open, and the fœtal limbs could be felt. Cold was applied to the vulva, and ergot with digitalis prescribed. About four hours after the fœtus was expelled. Ergot was again given to assist the expulsion of the placenta, but after two hours, during which the hæmorrhage was trifling, the os was found nearly closed and the cord running into it. Matters remained thus for three days; ergot had no effect. The hæmorrhage, though slight, was constant. I insisted on giving chloroform and exploring the uterus, but she objected. Latterly she was anæsthetised with difficulty. The hand was passed into the vagina, as recommended by Dr. Barnes,[*] and the finger swept round the uterine cavity, when the placenta was found free from attachment, and removed with ease. Made a rapid recovery.

Case 2.—Mrs. W——, aged twenty-five, in fourth month, first abortion, second pregnancy, began to lose blood without apparent cause. Opium and horizontal rest were prescribed with temporary success. On the third day after, hæmorrhage returned greatly increased, with severe bearing-down pains. I was told "all was away," and found the fœtus lying among a mass of coagula. I searched in vain for the placenta. The os admitted the point of the finger, but the uterus was too high to be explored satisfactorily. I took the usual precaution to abate hæmorrhage, and administered ergot repeatedly. In twenty-four hours expulsive action was evoked, accompanied several times in the intervals with a gush of blood. Feeling the placenta dilating the os, and having tried in vain to liberate it with the fingers and ovum forceps, I introduced my left hand into the vagina with comparative ease, and steadying the uterus above the pubes with the right, insinuated two fingers between the placenta and uterine wall, and instantly brought away the mass entire. She made a good recovery.

Case 3.—Mrs. McD——, aged twenty-six, in tenth week, first abortion, first pregnancy, six months married, had been doing some extra cleaning, and was attacked with slight hæmorrhage and bearing-down pains. She continued to work till compelled to desist from increase of hæmorrhage and pain. Os closed, cervix remarkably elongated, from which the probability of averting the impending danger was inferred. I prescribed Battley's solution, with digitalis and sulphuric acid, light diet, horizontal posture, abstinence from fermented liquors, and cold to the vulva. On the following morning the ovum was shown me entire, having been expelled during the night. This was rather unexpected, from the condition of the os and cervix the previous evening. Recovery was rapid.

Case 4.—Mrs. McA——, aged twenty-five, in tenth week, first abortion, first pregnancy, four months married, when assisting in hanging pictures, was suddenly seized with severe pain and hæmorrhage. Four hours after I found the ovum unruptured lying in the vessel. Patient was extremely sorry at her mishap, having a strong desire for offspring. She was kept in bed ten days and carefully nursed. She convalesced rapidly. After twelve months she consulted me in regard to her not being again pregnant. Is healthy, menstruating easily and regularly, but complains of dull pain over right ovarian region. The os is healthy, but pointing abnormally backwards and to the right. After repeated attempts I managed to introduce the sound. The uterus was flexed diagonally, its fundus lying in the left sacro-iliac synchondrosis. On the least rotation of the sound unbearable pain was produced. Subsequently I made several similar trials with the same result. It is three years since she aborted, and, though healthy, has not again conceived.

Case 5.—Mrs. A——, aged twenty-eight, in fourth month, first abortion, third pregnancy, without apparent reason had an oozing of blood for five days, when it greatly increased, accompanied with violent bearing-down pains. I found her very weak. She said it was a miscarriage, and handed me a fœtus about one inch long wrapt in a bit of newspaper. I examined the clots, soiled cloths, &c., for the secundines without finding them. The os was almost closed, and nothing protruding from it. I prescribed ergot, digitalis, and sulphuric acid, rest, low diet, &c., and left her comfortable. Next day she felt perfectly well; a vaginal examination showed only a slight sanguineous discharge and tumidity of the labia uteri. On the second day she was in the same condition; no pain, resting quietly. In the afternoon I was hurriedly summoned, as she had suddenly flooded. Os still closed. Having stanched the hæmorrhage by stuffing the vagina with sponge wet with vinegar, as recommended by Dr. Dewees, and taken other precautions to prevent bleeding, I left. Two hours after she had lost no more blood, but was extremely weak, with a dicrotic pulse, and a presentiment that she was about to die, "as she once had a sister who died from the same symptoms." Suddenly she felt as if the bowels would move, but could not. I withdrew the sponge, gave a large simple enema, and retired to the adjoining room. In about five minutes I was called, and found the placenta expelled entire with the enema, but no fæcal matter. Recovery was rapid.

Case 6.—Mrs. P——, aged twenty-four, in third month, first abortion, first pregnancy, six months married, had been losing blood for two days, accompanied with severe pain. I was shown "something that had come away"—part of the fœtal involucra. I prescribed rest, ergot, sulphuric acid, and digitalis. The hæmorrhage was trifling. Next day she had a slight attack of metritis, the lochia becoming fetid, which was allayed by opium, poultices over the abdomen, with vaginal injections of an aqueous solution of hydrochloric acid. On the whole, recovery was tedious. Three months after she began to menstruate, having missed the previous term. Had no pain, but felt sick; os closed; bleeding trifling. She was kept in the horizontal posture, and laudanum, digitalis, and sulphuric acid given. The hæmorrhage ceased in two days, and she was going about in a week. Two months after she lost about six ounces of blood per vaginam. It began while using a light wooden rake in a garden plot. There was no pain nor sickness. The last mixture was again prescribed, and the utmost quietness enjoined. In four days the hæmorrhage ceased; in two weeks she was going about. Latterly has had a living mature male child; breech presentation.

Case 7.—Mrs. D——, aged thirty-two, in fifth month, second abortion, fifth pregnancy; attributed her mishap to prolonged grief. I found her nearly pulseless from loss of blood, while a male fœtus about twelve inches long, with the cord and placenta attached, lay among the hæmorrhage. Still bleeding profusely, cold was applied to the vulva and abdomen, the vagina stuffed with sponge soaked in a weak solution of perchloride of iron, and brandy with ergot given. As the bleeding resisted the usual means of arrestment, she was put under chloroform on the third day, and the uterus explored. The os was open and patulous, but except one or two small clots, nothing was found in its cavity. Next day, the napkins being still largely stained with florid blood, I introduced an elastic catheter, with the opening at its point, into the uterus, and injected about half an ounce of aqueous solution of iron alum (strength two scruples to the ounce), which had the desired effect. In two days the injection had to be repeated, after which the bleeding gradually stopped. I had ceased attending for a week when she took a sudden flooding after washing her feet in hot water. The same means were employed as hitherto, and were attended with the same difficulty. After a course of iron and quinine she eventually recovered.

---

[*] Obstet. Oper., p. 391, second edition.

Case 8.—Mrs. A——, aged twenty-eight, very anæmic. Eleven weeks previous to my visit had a mole abortion at third month. Had a living child the first year of her married life; had three consecutive abortions since, of which the mole was the last. This was preceded by much hæmorrhage, and at the time of visit (eleven weeks after) it had not ceased. The uterus was found somewhat retroflexed, and measuring three inches and a half, the os open, and its labia tumid. The uterine malposition was comparatively easily adjusted, though causing some pain. The organ apparently contained no shreds of membrane nor clots, nor was the discharge fetid. She was advised to keep her bed, use cold astringent injections, take chiefly albuminous diet, also milk, wine, steel, and quinine. In about three days the bleeding completely ceased, and in a fortnight she was fairly convalescent.

Twelve months after she again became pregnant, of which I was duly apprised, and reiterated my advice to avoid physical and mental excitement. She obtained my consent to reside a short time at the coast. A few weeks after she had to hurry to reach the boat. On arriving home she had slight hæmorrhage, shivering, felt sickly, also bearing-down pains, with backache. I found the os closed, but feared, from her abortive diathesis, another miscarriage. Stimulants were prohibited, a light diet ordered, with rest and quietness in the horizontal posture, and solution of opium with digitalis prescribed. This treatment seemed successful, and in a week I ceased visiting. In two days I was called, when the ovum entire was shown me. It contained a three months' embryo. Recovery was rapid, after which she resided some weeks at the seaside, having salt water baths daily, and taking compound syrup of phosphate of iron, with a regular allowance of light dry sherry.

In five months she was again pregnant. Being extremely anxious for offspring, and remembering previous experience, she put herself entirely under my care, and ultimately had a daughter at full term. Previous to her confinement there was much œdema of the lower limbs, slight swelling of the features, and considerable albuminuria. These gradually disappeared under appropriate treatment after parturition. She made a good recovery, and is now in better health than for some years. The child, aged twelve months, is well. She is again five months pregnant.

Case 9.—Mrs. J——, aged twenty-two, in third month, first abortion, first pregnancy, married four months. Two days before had been polishing a friend's table, the obvious cause of her illness. I found her much depressed and vomiting. There was little bleeding, but severe and frequent bearing-down pains. The ovum was projecting through the os. A dose of ergot was given. After an hour, no change taking place in her condition, I left. On my return in six hours I was shown the ovum entire, newly cast off. The hæmorrhage was trifling. Three days subsequently she had a slight attack of metritis, which yielded to subchloride of mercury and compound ipecacuanha powder, with hot applications to the abdomen, and washing out the vagina with water acidulated with HCl; otherwise she made a good recovery.

Case 10.—Mrs. M'C——, aged twenty-eight, in the fifth month, first abortion, fourth pregnancy. When in her fourth month she had an oozing of blood from the vagina, with bearing-down pains—the apparent result of a long walk. She was kept in bed a week, and sedatives administered successfully. Soon after she had severe acute bronchitis, causing prolonged paroxysms of coughing, for which she was kept in bed two weeks. When scarcely recovered, an only child had inflammatory diarrhœa, causing her much anxiety and extra trouble. After he got well she set to a day's cleaning, in direct opposition to my emphatic instructions and also those of her husband. The same night uterine contractions began. I found little hæmorrhage; the funis prolapsed and pulseless. The presentation was footling; the lower half of the fœtal body lay in the vagina; the upper was grasped by the uterus. Traction on the limbs with two fingers failed to disengage it. Ergot with borax had no effect. During the next twelve hours I saw her several times. Latterly the fœtus was expelled. A large dose of ergot was given to assist in the expulsion of the placenta; the effect was again *nil*. On tracking the cord in the vagina, it was found entering the os, which only admitted the point of the finger. Causing an attendant to grasp the uterus over the pubes, I made slight traction on the cord with the right hand, and endeavoured with my left to dilate the os and otherwise assist in extracting the placenta; but the cord parted within the uterus. I tried to pass the hand into the vagina, but failed. There being still little bleeding, I resolved to wait and see what nature would do. Nature took matters easy. For two days she fed well, slept soundly, and was painless; but I was getting anxious. Chloroform was given, and with the left hand in the vagina and the right steadying the uterus over the pubes, I dilated the os to the size of a crown-piece, and found the placenta adhering to the left uterine wall and part of the fundus. The most extreme difficulty was experienced in getting it separated, the two fingers not being able to work at the fundus, nor the hand to enter the uterus; consequently, about two-thirds of it was extracted in small shreds. Latterly the adhesion was separated, and a good hold obtained of the remaining large part, which was liberated coincident with a uterine spasm. Five hours after the patient was flushed, and complained of headache; pulse 108. Next day the pulse was 72; headache gone. She recovered rapidly without a bad symptom.

Case 11.—Mrs. C——, aged twenty, in third month, first abortion, second pregnancy, after walking about seven miles, had bearing-down pains with profuse flooding. I found her supported by two persons and unable to move. She was put to bed, and as the pain was unusually severe, thirty minims of sedative solution of opium were given. The os admitted the finger, and the fœtal ovoid was found jammed in the cervix. A towel soaked in cold water was applied to the vulva, the pelvis raised, and the shoulders lowered. This lessened the hæmorrhage, while the opium soothed the pain. About three hours after her bowels inclined to move, she insisted on getting up, and fainted. On my arrival she was recovering, but blanched and nearly pulseless. Brandy had just been given, by which, with the horizontal posture, she revived. The membranes were now protruding, the hæmorrhage had ceased, and the pain was nearly gone. After waiting about an hour, and her condition remaining the same, ergot with borax was given, and, assisted by the two fingers grasping the membrane, resulted in the expulsion of the ovum entire. Patient made a fair recovery, and was pregnant four months after.

(To be concluded.)

OPHTHALMIC MEMORANDA.

By EDGAR A. BROWNE,

SURGEON TO THE EYE AND EAR INFIRMARY AND THE DISPENSARY FOR SKIN DISEASES, LIVERPOOL.

1. A case of partial staphyloma corneæ afforded an opportunity for trying a method of treatment which I do not remember to have seen previously employed.

C. S——, workman, St. Helens, having neglected a gonorrhœal ophthalmia of the right eye, was first seen when a large sloughing ulcer of the outer and lower third of the cornea was threatening perforation. Although the eye was rescued, a large staphyloma resulted. The protuberance was exceedingly unsightly, and gave rise to inconvenience by preventing closure of the lids. As useful vision upwards and inwards remained, the only ordinary method available seemed to be repeated paracentesis with pressure. But, considering how often this plan fails to do good even in small staphylomata, I resolved to imitate a process now in vogue for conical cornea, and operated (May 7th) by transfixing the most prominent portion of the tumour with a Graefe's knife. The incision was an eighth of an inch long, parallel to the long axis of the swelling, and obliquely inclined to its surface. The flap was seized with the iris forceps, and a tiny wedge-shaped piece was snipped off by the scissors. Firm pressure was then applied. I felt very doubtful of the capacity of the degenerated tissue for healing, and was delighted to find that the posterior edges of the wound had, in twenty-four hours, healed as readily as healthy cornea. The wound having completely cicatrised, though but little flattening had resulted, I again (May 28th) excised a wedge-shaped piece of tissue, about an eighth of an inch long and a line across at its widest part. This healed readily, and produced a marked improvement. On June 18th I excised a third piece with like favourable result. When cicatrisation was complete the staphyloma was considerably flattened (though not quite level with the normal surface of the globe), and the lids closed easily and comfortably.

The main points conducive to success seem to be, that the posterior edges of the wound should be in apposition, and that a large piece of tissue be not removed at one sitting. As the operation is nearly painless, it might be repeated a dozen times if necessary.

2. Wound of an ocular muscle without injury to the globe is necessarily a rare and curious accident. The following is the only case I have ever seen.

J. K——, iron-roller, St. Helens, was hit by a flying fragment of metal between the lower lid and the globe, neither of which, strange to say, was injured. He applied at the infirmary some weeks after the accident on account of vertical diplopia. On inspection, an upward squint was manifest, and the power of downward movement was considerably impaired. At the bottom of the retro-tarsal fold was an irregular cicatrix, and the lower part of the ocular conjunctiva was red and much thickened. On June 11th I operated by snipping a free horizontal opening in the conjunctiva, about an eighth of an inch from the corneal margin. The tissues were matted together, but by careful employment of scissors and hook the attachments to the globe were freed; the tendon remaining joined to the conjunctiva. The superior rectus was now divided, and the lower tendon brought forward by three silk sutures, which were drawn sufficiently tight to give the eyeball a slight downward inclination. The wound healed readily; but when the superior rectus regained its power the improvement was found to be only partial, and I therefore (August 6th) brought the inferior rectus still further forward by a second operation, but did not again divide the superior tendon. The pupil was at first half its diameter lower than its fellow, but after the withdrawal of the sutures it gradually rose till it was level. The patient was discharged cured.

Liverpool.

ON THE TREATMENT OF ALVEOLAR ABSCESS.

By ISIDOR I. LYONS, M.R.C.S., L.D.S.

Alveolar abscess is the result of an acute inflammation of the periodental membrane. This may arise from various causes. It is commonly the sequel of acute inflammation of the pulp of a tooth, but it may commence in the membrane. An alveolar abscess generally points opposite to the buccal or labial surface of the affected tooth, or the pus may exude at its neck or travel along the hard palate and open at any point internal to the dental arch.

Among the different local remedies prescribed for this affection, the most common are external fomentations and poultices. This treatment is to be deplored for the following reason. When, for example, an abscess takes place at the root of an upper bicuspid tooth, and the swelling is at its buccal surface, on a poultice being applied externally, pus would travel above the fold of mucous membrane connecting the superior maxilla with the cheek, and appear among the buccal muscles, ultimately passing through the skin, thereby producing those ugly scars often seen on the face of patients who have undergone this treatment. The following cases are typical of these results.

Isabella B——, aged twenty-eight, admitted into St. Bartholomew's Hospital April 1st, 1875, under the care of Mr. Callender. This patient had suffered great pain for a long time from a carious lower molar, at the roots of which there had been an abscess. This had been treated by external fomentations and lancing of the gum. When admitted into the hospital, there was a soft red spot with two or three openings over the middle of the lower jaw, on the right side, extending behind towards the angle and ramus, and slightly down to the neck. There was also inability to open the mouth except to a very slight degree. The first lower molar was reduced to a stump. Since admission, the swelling behind and below has increased, and apparently suppuration taken place. On April 9th the right lower molar (which was necrosed) and the fangs of the two other teeth were extracted. On the 16th the abscess appeared to be discharging through openings in front of it. As regards the rest of the history of this patient, an attack of erysipelas supervened, involving both sides of the face, and which was remarkable for its severity and high temperature. On June 16th she was discharged, her general condition much improved.

Emily C——, aged twenty-four, admitted as an out-patient of the hospital April 8th, 1875, under the care of Mr. Coleman. This patient had acute periodontitis of the first left upper molar in the previous March, and was ordered to apply poultices externally. Within a week the abscess burst. In April she came to the hospital to have the tooth extracted. At that time the scar extended from that part of the cheek opposite the zygomatic arch to midway between it and the angle of the mouth.

G. S——, aged twenty-one, admitted as an out-patient on March 21st, 1875, under the care of Mr. Coleman. This patient had suffered from acute periodontitis of a left lower molar for one month; and, an abscess supervening, it was treated by external fomentations and poultices. At present there is a fistulous opening in the cheek.

The appropriate treatment in the above cases would, no doubt, be the immediate extraction of the offending teeth; but if desirous of saving them, by internal fomentations (the patient to be desired to bathe his mouth frequently with water at as warm a temperature as possible), also by lancing the gums and the application of leeches, and, when an abscess has formed, by free incisions.

The cases given are types of a very large number of out-patients seen at the dental department of the hospital.

ST. THOMAS'S HOSPITAL.

CASE OF HYDROPHOBIA.

(Under the care of Mr. Sydney Jones.)

A point of interest in the following case, for the notes of which we are indebted to Mr. H. P. Potter, house-surgeon, was the benefit derived from the inhalation of chloroform. Although the case unfortunately proved fatal, the chloroform gave considerable relief.

Henry W——, aged twelve, a very healthy boy, rather hot-tempered but not nervous, applied at the hospital on September 24th, at 1 P.M., suffering from symptoms of hydrophobia. He had had no previous illness. The boy stated that six weeks ago, whilst stroking a dog which was chained, the animal snapped, and caught hold of his right little finger, and he had to pull it forcibly out of its mouth. No one else was bitten. The dog was killed two days after, and was said to be suffering from rabies. The finger was simply bound up in rag for two days, when he came to the hospital, and poultices were ordered. The wound healed in about a fortnight. During the interval the boy was pretty well, but sometimes he was rather strange in his manner; never spoke of fear of hydrophobia. On the evening of the 19th September he was taken with rigors, and complained of pain shooting up the right arm from the bitten finger; nothing amiss was noticed about the wound. The boy went to bed at once, and passed a restless night. The next morning he was better; ate and drank well. On the 21st he began to refrain from food; said he would take it "by-and-by." On the 22nd spasms were first noticed, when he drank fluids. Since the night of the 20th he had not slept; had been very hateful; had had illusions, and frequent and copious micturition. The spasms and restlessness increased up to the day of admission, on the morning of which he foamed at the mouth. He had no aversion to animals, and he caressed the cat just before leaving for the hospital.

On admission at the Casualty department the patient had a most anxious and woful expression, gasping for breath like a child after a fit of crying; at each inspiration the angles of the mouth were drawn downwards and the eyes opened. The face was pale and cold. There was an old cicatrix at end of right little finger; nail not quite renewed; no redness nor tenderness about it. Pain shooting up right arm and down the right side. Bowels were said to have acted freely after some jalap powder on the 20th.

The patient was admitted into Edward small ward. At 3 P.M. was seen by Mr. Jones. Appeared in a state of great nervous excitement, but at intervals could answer questions rationally. On the least excitement, as of drawing bed-clothes up or down, or when spoken to quickly, the muscles of the face and neck were spasmodically affected, the chin thrown up, and angles of mouth drawn down. On trying to swallow fluid (to which he had strong aversion) the spasms were most intense; he gargled, and at last swallowed part of the liquid, while part was expelled by the mouth. Pulse 88, quiet; temperature 101·2°; skin warm; feet comfortably warm. No pustules nor enlarged glands seen beneath the tongue. Five grains of calomel in glycerine, and the sixth of a grain of the extract of belladonna every four hours. Hot bottles to feet. — 4 P.M.: About the same. Said he saw a big dog on the ceiling. Answered rationally but refused fluids and ice. On bringing an ice-bag in contact with the head intense spasms were excited. Pulse risen to 140. — At 10 P.M. Mr. S. Jones saw the patient, as he was much worse. He raved and was greatly excited if looked at fixedly; spasm more or less at each inspiration; answered questions, but angrily; pugnacious, tried to bite and scratch bystanders. Bowels acted freely after turpentine enema. Pupils fairly dilated; perspiring. Temperature risen to 102°; pulse 130 to 140; respiration 24. Chloroform inhaled with most marked effect; instant relief. As soon as insensibility was produced, he breathed tranquilly, the inspiratory spasm being entirely lost; slight tracheal rhonchus, as of mucus. Mr. S. Jones then determined to keep patient under the influence of chloroform, and gave an enema of fifteen grains of bromide of potassium, with ten of chloral hydrate, every four hours. 11 P.M.: Respirations at long intervals, and gasping. He neither moved nor spoke. Previous laboured breathing became quiet. Pulse accelerated, and slightly stronger. Appearance tranquil. Temperature 101°; pulse 130.— 11.45 P.M.: Chloroform given with Clover's apparatus for two hours, but left off on account of accident with bag. Warm bricks retained in bed, and patient packed with blankets. Ice applied to nape of neck brought on spasms and general disquietude. — Midnight: Nutrient enema, with half an ounce of brandy, fifteen grains of bromide of potassium and ten of chloral hydrate, given and retained. Chloroform kept up. Abdominal muscles rather tense. Thoracic breathing, with great uplifting of trachea. Feet and hands comfortably warm.

Sept. 25th.—1 A.M.: Patient allowed to recover sensibility for a short time. He sighed very much, tossed his head from side to side, and threw his left arm about. Temperature 101°.—1.30 A.M.: Chloroform still used. Patient appeared more exhausted. Breathing slower and less deep; extremities warm; pupils moderately contracted.—4.30 A.M: Fully under chloroform. Tracheal rhonchus; skin hot and dry. Temperature 102·8°; pulse 160; respiration 42. Had not passed urine since admission. Bladder not distended; eyes congested.—4.45 A.M.: Enema of fifteen grains of bromide of potassium, ten of chloral, and half an ounce of brandy; eggs and beef-tea. — 5 A.M.: Subcutaneous injection of one-sixth of a grain of morphia. Chloroform administered for about half an hour after the morphia injection, when the pupils were contracted to the size of a pin's head. He then seemed fully under the influence of morphia, and no chloroform was required till 6.30, when he came to, and the spasms at each inspiration recommenced. Chloroform repeated. — 6.30 P.M.: Temperature 102·6°; pulse 120, very soft and feeble; respiration 26. Rhonchus all over the front of the chest. Face congested; eyes half opened and turned upwards; skin dry and warm. Had not passed water nor motions. Bladder not distended; abdomen tympanitic; hands blue.—7.20 A.M.: Died. Before death the tracheal rhonchus became more and more marked; lividity of hands and feet correspondingly increased. During the last fifteen minutes of life the inspirations became irregular; the inspiration prolonged, accompanied by much rattling in the larynx. Artificial respiration kept up for ten minutes. Pupils widely dilated. Thermometer introduced into the right axilla ten minutes before death, 101·7°. Respiration ceased at 7.20, though the heart's action continued for some short time after.

Autopsy, fifty hours after death.—Body much decomposed. Results mostly negative. Brain congested. On section, the grey matter, both external and internal, was unusually distinct and congested. Numerous vessels in the white substance. Internal organs congested; tongue congested.

ST. BARTHOLOMEW'S HOSPITAL.

STRANGULATED UMBILICAL HERNIA IN A WOMAN; GANGRENOUS INTESTINE; FÆCAL FISTULA MADE; DEATH SIX DAYS AFTER OPERATION.

(Under the care of Mr. WILLETT.)

FOR the notes of the following case we are indebted to Mr. James Shuter, M.A., LL.B., house-surgeon.

E. E——, aged forty-four years. Had had an umbilical hernia for ten or fifteen years, often strangulated, but always reducible by taxis.

Oct. 24th, 1874.—At 11.30 A.M. the hernia became strangulated. At 5 P.M. Mr. Willett reduced a portion of the hernia by taxis, leaving what seemed to be thickened omentum. Symptoms were at once relieved.

25th.—12 noon: Hernia redescended during the night; she complained of pain at the hernia, and of sickness. Tumour was larger than on the previous day. A dark-coloured patch was noticed at umbilicus.

26th.—5 P.M.: Admitted to Casualty ward.—At 8 P.M. gangrene of covering of hernia had gradually extended. When under chloroform, Mr. Willett made a free opening into the sac, and found the contents of omentum and small intestine strangulated by the fibres of the linea alba, and part of it gangrenous and constricted, the result probably of the first strangulation. The stricture being relieved, the intestine was laid freely open, and the edges stitched to the sides of the wound. Pulse 120; temperature 101°. Subcutaneous injection of a quarter of a grain of acetate of morphia at night.

27th.—10 A.M.: Continuous retching; complexion dusky, areolæ under eyes; pupils rather contracted. Patient had slept well; had taken four ounces of brandy in water, one teacup of milk, and half an ounce of essence of beef. Ice and brandy kept down. Pulse 114; temperature 99°. Injection of a quarter of a grain of morphia. Tongue fairly clean and moist.—2.30 P.M.: Comfortable, and under the influence of morphia; tongue rather more furred; retched, but did not vomit. Pulse 108.—8.30 P.M.: Intestine was opened in a fresh place for escape of gas; essence of beef retained. Injection of a quarter of a grain of opium. Pulse 108; temperature 100°.

28th.—11.30 A.M.: Hands cool; patient very excited and asks for brandy; is in no pain; passes her water; fæces and gas escape from false anus; tongue moist, white fur. Had a pint and a half of milk with two ounces of brandy during the night; all vomited. In the morning had half a pint of milk with five ounces of brandy, but all was vomited. Pulse 100; temperature 98·4°. Subcutaneous injection of a quarter of a grain of acetate of morphia.—8.45 P.M.: Not sick since 11.30 A M. Had half a pint of beef essence, one ounce of brandy, and a pint of milk for dinner. Had four ounces of beef essence for tea. Pulse 108; temperature 98·2°.—11.45 P.M.: Tongue clean; no vomiting. Pulse 114; temperature 98·3°.

29th.—Morning: Slept fairly well; retched slightly, but did not vomit. Had half a pint of milk and one ounce of brandy. Pulse 100; temperature 98·4°.—3.30 P.M.: Pulse 100; temperature 98·4°.—Evening: Slight pain in right iliac fossa, which went away when she was moved; liquid fæces and gas escaped from false anus; vomited forcibly. Had a pint and a half of beef essence, two pints of milk, and three ounces and a half of brandy. Pulse 110; temperature 99·6°. A quarter of a grain of acetate of morphia subcutaneously.

30th.—Morning: No vomiting since last night; tongue clean and moist. Pulse 114; temperature 101·1°.—11.30 A.M.: Had half a pint of essence of beef, half a pint of milk, and one ounce of brandy during the night; half a pint of milk since 8 A.M. Pulse 118; temperature 101°. Had a quarter of a grain of acetate of morphia subcutaneously.—3 P.M.: Began to vomit. Charcoal poultice put to wound.—3.30 P.M.: A quarter of a grain of acetate of morphia subcutaneously. Midnight: Vomited some essence since 7 P.M.; pulse intermittent about four times per minute. Pulse 121; temperature 101·2°.

31st.—Morning: Did not sleep all night; vomited everything.—9 30 A.M.: Pulse 128; temperature 101°. Had a third of a grain of acetate of morphia.—1.30 P.M.: Slept about three hours; has taken nothing; vomited little; fæces pass from aperture. Pulse 144; temperature 100·5°.—11.45 A.M.: Tongue covered with brown fur and rather dry, especially at tip; has been spitting sharply with tight lips about three times per minute; feels very weak, but has no pain. Had half a pint of milk with ice, and four ounces of brandy, but vomited all, also three cups of tea. Pulse not to be counted for rapidity; temperature 100·7°. Acetate of morphia five-twelfths of a grain.

Nov. 1st.—Died at 1 A.M.

Autopsy.—Abdominal parietes from above umbilicus to the pubes, and for some distance laterally, were greatly swollen, infiltrated, and congested; omentum and large knuckles of small intestine projecting from the wound were gangrenous; there were offensive gases and much opaque fetid fluid in the peritoneal cavity. The brain was not examined. The other organs were healthy.

ROYAL INFIRMARY, EDINBURGH.

TWO CASES OF AMPUTATION THROUGH THE HIP-JOINT; RECOVERY.

(Under the care of Prof. SPENCE.)

FOR the following notes we are indebted to Mr. J. Allan Gray, M.A.

CASE 1. *Morbus coxæ; excision; amputation; recovery.*—Thomas H——, aged twenty, a clerk, was admitted into Ward 13 on Sept. 24th, 1874. The history records a series of abscesses near the hip-joint on two different occasions: once at the age of ten, when he had injured his hip by a fall; and again five years ago, when convalescing from relapsing fever. Last May he had an attack of hæmoptysis.

On admission he was seen to be a delicate, anæmic-looking young man, emaciated to the last degree, and suffering evidently from advanced morbus coxarius — a diagnosis which examination confirmed. He was ordered wine and a ferruginous tonic; the sinuses at the hip to be dressed with lotion of chlorinated soda, and extension apparatus to be applied. At first he seemed to improve rapidly, due no doubt to the altered regimen and rest; and after residence for five weeks in hospital he was so much better as to be deemed fit for operation. The joint was accordingly excised on Oct. 29th. For a time he did well, but the discharge was always free, and often fetid; his health, however, remained wonderfully good, notwithstanding the great strain. On Nov. 17th he had a slight attack of pleurisy, and on Dec. 20th examination with the probe showed a piece of dead bone yet to separate. About this time he began to complain of pain in the region of the liver, which was seen to be greatly enlarged, and was most probably affected with amyloid degeneration. For this, counter-irritation with tincture of iodine was applied every second day, and seemed to do some good. On Jan. 28th a small piece of bone which was pressing on the cicatrix of the excision wound was snipped off. But during all this time the discharge was very free, and the patient seemed to lose ground. This state of matters continued, and on April 3rd half an inch of the upper end of the femur and some loose necrosed portions of bone were removed. After this the patient appeared to be sinking fast, and, as a last resource, amputation at the hip-joint was had recourse to.

April 13th.—Pulse 84; temperature 99°; urine still with a trace of albumen. To-day Prof. Spence amputated the limb at the hip-joint. The patient having been placed under chloroform, Esmarch's (flat) elastic bandage was applied tightly to the limb from the foot upwards, so as to extrude all blood from the part. An india-rubber band was next brought round the thigh, immediately below the pelvis, drawn tight, and secured by being again passed round the limb and tied. The flat roller was then removed. Mr. Annandale now compressed the femoral at the pelvic brim, while Prof. Spence transfixed the limb and cut the anterior flap by the usual method. This he gave in charge to Dr. Duncan. The posterior flap was next cut, so as to have for one of its margins the incision made on the 29th October last for the removal of the head of the femur. The femoral artery was immediately tied and the other arteries secured. A small projecting necrosed portion of the acetabulum was then removed with bone-pliers, and the surface of the flaps, especially where the remains of sinuses were observable, washed with a solution of chloride of zinc (twenty grains to an ounce of water). The flaps were then brought together along the margins by silver-wire sutures, the extremities being left free for drainage. A pad of lint was laid along each edge of the wound, a fold of boracic lint over its surface, and the whole secured with a broad flannel bandage around the pelvis.

Though the patient lost little blood, yet towards the end of the operation his pulse became very weak. On this indication ether was substituted for chloroform as an anæsthetic, and an enema of brandy-and-water given, which had the effect of strengthening the pulse. The enema was repeated on the patient being put in bed, and champagne and brandy-and-water ordered in frequent small doses.

14th.—Morning: pulse 110; temperature 100°. Evening: pulse 112; temperature 100°. Slept a little through the night, and does not complain of much pain. Takes beef-tea and milk.

15th.—Morning: pulse 118; temperature 101·6. Evening: pulse 112; temperature 99°. Urine of sp. gr. 1012, with a trace of albumen.

19th.—Pulse has never been above 120, nor temperature above 99·6°, since the 15th inst. The stump looks well; a part towards the inner aspect has healed by first intention, and the discharge is decreasing. Patient is looking and feeling better than before the operation; sleeps well now, and takes his food. The urine still contains a trace of albumen.

30th.—Patient improving in every way. Temperature has been normal since the 19th instant, and continues so. Appetite good. The wound has healed with the exception of a small point in the centre of the incision, through which some discharge comes, and that part of the posterior flap which was formed of a previous incision. The latter, however, is healing well by granulation. Urine yet contains a trace of albumen, and liver dulness remains much as before.

May 27th.—Stump looking better, and patient much stronger. Urine slightly albuminous. Sent to Convalescent House.

Oct. 8th.—Patient's health since his discharge has continued good. Wound is now healed.

CASE 2.—*Chronic necrosis of femur; amputation through hip-joint; recovery.*—Lilian S——, aged nine, was admitted to Ward 15, on 10th July, 1874, suffering from necrosis of femur and fibula. On admission, the leg was found flexed on the thigh from the contraction of the hamstring tendons, and the signs of extensive necrosis of the femur were abundantly observable. Patient remained in the ward until 20th January, 1875, when she was dismissed to the Convalescent House. During this time several pieces of dead bone were removed—one a sequestrum three inches long—and the wounds were dressed with chlorinated soda or dilute carbolic lotion, the patient meanwhile taking internally small doses of steel drops and dilute phosphoric acid. On 17th February she returned from the Convalescent House, and had the hamstring muscles divided, so as to straighten the limb. Dismissed again on 4th March, and admitted once more on July 26th with the thigh in a state much as formerly. Examination with the gunshot probe showed a large amount of dead bone still to separate. The necrosis, besides being extensive along the shaft of the femur, implicated the great trochanter. Amputation at the hip-joint was accordingly determined on as a last resource; for the general health, although never very good, had lately been failing.

Aug. 3rd.—The limb was amputated at the hip-joint by anterior and posterior flaps. The femoral and profunda arteries were secured with silk ligatures.

Since the operation patient has never had a bad symptom. The ligatures came away on the 17th August without any hæmorrhage.

Oct. 1st.—Patient is now able to walk about on crutches, and is in health much better than before the operation.

BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.

CASE OF OVARIAN TUMOUR SIMULATING EXTRA-UTERINE PREGNANCY, WITH COMPLETE EXTRUSION OF UTERUS AND BLADDER; SUCCESSFUL OVARIOTOMY AND CURE OF THE EXTRUSION.

(Under the care of Mr. LAWSON TAIT.)

H. L——, a handsome brunette, aged eighteen, had menstruated regularly from the age of thirteen until twelve months ago, when the catamenia suddenly ceased, and the abdomen began to enlarge. In February last she was seen by several practitioners, who all pronounced her to be pregnant, and in a letter from one of them it is stated that she had morning sickness, irritability of the bladder, darkened areolæ, and that the writer was positive he had felt movements and heard the fœtal heart. At the end of June she had what seemed to be the expulsive pains of labour; but, as the uterus was found to be virginal, and to be completely extruded from the vulva, it was supposed that the pregnancy was extra-uterine. In the beginning of July she consulted Mr. Tait, who diagnosed an ovarian tumour, multicystic, and advised its removal. Between his first and second visits one of her attendants communicated the facts of the history given above, and they were enough to make Mr. Tait hesitate in his opinion, until he had examined her under ether. The more complete examination confirmed his previous opinion, and on August 18th he removed the tumour. The cysts were so numerous that the mass was practically solid. The pedicle was very long, broad, and triangular in shape, extending from the cæcum upwards and inwards to the tumour, and downwards and inwards to the extruded uterus. In order to cure the displacement of the pelvic organs at the same time that the tumour was removed, Mr. Tait pulled the inner part of the pedicle as far up as he could, and clamped it close to the right ureter.

The patient recovered without a single bad symptom, began to menstruate on the 5th of September, ceased on the 9th, and went home on the 10th with the uterus and bladder in their normal positions.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

THIS Society met for the first time this session on Tuesday, the 19th inst.; the chair being filled by the President, Mr. George Pollock. At the commencement of the proceedings the President laid upon the table a copy of the new volume (No. 26) of the Society's Transactions, remarking upon the difference in bulk between that volume and the first issued by the Society. The specimens brought forward were, many of them, of striking interest and rarity.

Dr. CAYLEY exhibited a specimen of Hydatid Cyst of the Liver, which burst into the lung. It was procured from the body of a man, aged thirty-two, who was sent to the London Fever Hospital as a case of typhoid. His illness was of seven weeks' duration. There was some dyspnœa, slight cough, pain in the right side, and dulness at the lower part of right back. Dr. Cayley, thinking the case to be one of circumscribed empyema, was on the point of performing paracentesis, when the patient coughed up numerous hydatid vesicles. Puncture was then made in the posterior axillary line, and two pints of turbid yellow fluid, containing cysts, were drawn off. The hydatid expectoration, however, continued; and in spite of further attempts at complete evacuation, including the introduction of a drainage-tube and injection of water, the patient died suddenly, suffocated by hydatids. There was found a large hydatid cyst in the upper part of the liver, communicating with a cavity in the base of the lung; the bronchi and trachea were plugged with hydatid vesicles, a number of which were still contained in the mother cyst in the liver. The intestines were normal. Two years before his death the patient had been treated for enlargement of the liver; and on the present occasion the extension of hepatic dulness was ascribed to depression of the organ from the supposed empyema.—Mr. MAUNDER inquired whether the admission of air into the cyst had led to decomposition, or to any injurious effects to which death might be ascribed. — Dr. CAYLEY replied in the negative; and stated that death was due to the blocking of the air-passages by the vesicles.

Dr. PEACOCK showed specimens of the Skin and Supra-renal Capsules from a case of Addison's disease. The patient, a female, presented in a marked degree the constitutional symptoms of the affection. She suffered from dyspepsia and vomiting, and died somewhat suddenly from asthenia. The skin was markedly bronzed, the pigmentation being most marked in the axillæ, areolæ of nipples, &c. She had always had a dark complexion, and two years before had suffered from general eczema. There was marked pigmentation of the buccal mucous membrane. On post-mortem examination, beyond two cretified nodules at the apex of one lung, with fibroid thickening of the pleura, and adhesion of the liver to diaphragm, there was no disease found save in the supra-renal capsules, both of which presented the characteristic changes in a fairly advanced condition.—Dr. GREENFIELD, who had made the examination, supplemented Dr. Peacock's account by some valuable remarks. The microscopical appearances of the diseased capsules confirmed those of previous observers. He remarked further upon the extensive adhesions, of a firm fibrous character, involving the whole of the abdominal viscera; and in this case, as in another which he had seen, he met with fine glistening pearly nodules in the peritoneal adhesions. This fibrous thickening and adhesion in the vicinity of the capsules had been insisted on by Dr. Greenhow as a very constant morbid appearance. The right capsule was firmly adherent to the liver. The spleen was large and tough. The pigmentation of the tongue was peculiar, in occurring in patches on the surface of the organ, leaving the papillæ free, the exact converse of what had been found in the other case he had seen.

Dr. PEACOCK also showed a specimen of Ulceration of the Stomach from a man, forty-two years of age, of intemperate habits, who, five weeks before admission, had swallowed a tablespoonful of sulphuric acid. He suffered from severe attacks of vomiting of dark, grumous matter, and a curious feature in the case was the appearance of a firm tumour in the epigastrium, which receded at every attack of vomiting. The tumour was probably due to spasmodic constriction of the stomach. The man lived for three weeks, and died of exhaustion. Widespread ulceration of stomach and constricted pylorus were found.

Dr. PEACOCK further exhibited a specimen of Congenital Disease of the Aortic Valves, taken from a girl twelve years of age, who, during life, had presented the symptoms of aortic regurgitation and obstruction, and of slight mitral constriction. She suffered much from vomiting, had a very low temperature (not often above 95°), and was twice tapped for ascites. She died dropsical. There were only two aortic valves, about equal in size, one of them being retroverted and showing the remains of the raphé on its aortic surface. There could be no doubt that this condition was congenital. There was no history of rheumatic fever. In answer to the President Dr. Peacock stated that the symptoms came on gradually.—Dr. GREENFIELD said, in confirmation of Dr. Peacock's view of the case, that the patient had been under his observation for several years, and throughout the disease had run a chronic but slowly progressive course.—Dr. PEACOCK added that at first he thought the condition might be ascribed to intra-uterine endocarditis, but from the frequency with which it occurred together with the absence of any rheumatic history in many cases, he had come to the conclusion that it was due to arrest of development.

Dr. DOWSE showed a specimen of recent Hæmorrhage into the Pons Varolii and Fourth Ventricle, from an old woman who had suffered from left hemiplegia for two years. When seen she was seized with an attack of right-sided convulsions, became profoundly comatose, with contracted pupils, facial palsy (right), &c. There was found subarachnoid hæmorrhage over cerebellum; and a large clot involving both halves of the pons, which had ruptured on the left side. Traces of old hæmorrhage were found in the grey matter of the right cerebral hemisphere.

Dr. DOWSE also brought forward a specimen of Subarachnoid Hæmorrhage of the Spinal Cord, which occurred in a man aged fifty, who, after a convulsive seizure, had recovered to a slight extent, when he was attacked with general convulsions, and fell into a semi-comatose state, marked by muttering delirium and subsultus tendinum. There was marked paraplegia, while the upper limbs were paralysed and rigid. The lower limbs were hyperæsthetic, reflex excitability being increased. He died comatose within thirty-six hours. There was great vascularity of the cerebral pia mater, with subarachnoid effusion over the posterior lobes, the anterior lobes being free from extravasation. There was subarachnoid hæmorrhage down the whole length of the cord. The source of the hæmorrhage was probably miliary aneurisms.

Dr. DOWSE showed a specimen of Thrombosis of the Internal Carotids, taken from a woman aged sixty-six, in whom the symptoms, when first seen, were semi-coma, aphasia, perfect paralysis of right arm, imperfect of right leg, hyperalgia and hyperæsthesia of both limbs; no marked facial palsy. Ten days after this attack, while the right arm was still paralysed, the patient was seized with left hemiplegia, and died comatose. The brain was remarkably anæmic, with the exception of the anterior half of the right hemisphere, which was of a pink colour, and on section points of softening were found in the second and third frontal convolutions (left), while the right half of the brain was congested. Both internal carotid arteries were plugged. He could not explain the reason of the anæmia of the left and congestion of the right half of the brain.

Mr. BUTLIN showed a specimen (illustrated by some beautiful drawings and microscopical sections) of Colloid Carcinoma of the Breast, removed by Mr. Savory from a female forty-three years of age. The tumour, which was of the size of a small egg, had been growing for one year. On removal it was of firmer consistence than usual with colloid tumours. The microscopical characters were those of typical colloid cancer.

Dr. GREENFIELD brought forward a remarkable case of Aneurism of the Anterior Communicating Artery of the Brain. The patient, a bricklayer, aged forty-five, fell fifteen feet from a scaffold, was picked up insensible, and brought to hospital on May 31st suffering from cerebral concussion. There was inability to stand, but no loss of motion or sensation in lower extremities; fracture of left innominate bone was discovered. Was going on well, when on June 8th he died suddenly in a fit. At the autopsy, beyond a scalp wound there was no injury to the head. A small quantity of blood was found beneath the arachnoid at base of brain, which was completely covered by blood and clot, surrounding medulla and upper part of cord, and filling the fourth ventricle. There was slight atheroma of the internal carotids, middle and posterior cerebrals and their branches. The anterior cerebrals were rigid; lying between them, just in front of the anterior communicating artery, was a small aneurismal sac the size of a sweet pea. It sprang from the inferior and anterior aspect of the vessel and contained firm clot. It was partly adherent to the two anterior cerebral arteries, and in its upper aspect its wall, which was very thin, was perforated by an aperture one-twelfth of an inch in diameter. Dr. Greenfield remarked that probably the hæmorrhage occurred at three or four different periods, and that it was one of these attacks that caused the man to fall from the scaffold. The quantity of firm clot at base of brain favoured this view. Aneurism in this region was extremely rare. He had only found one case on record—viz., by Dr. M'Dowall, in THE LANCET for August 7th, 1875, in which, however, the aneurism produced no symptoms. It was also of interest in a medico-legal aspect, since it was a question whether the patient's death was due to the fall from the scaffold. Probably he fell because of a fit due to the first rupture of the sac.—Dr. SEMPLE alluded to a case of aneurism of the basilar artery, which he had recorded in the Society's Transactions for 1870.

Dr. GREENFIELD also brought forward a case of Tumour of the Left Anterior Cerebral Artery, leading to thrombosis in that vessel. The patient, a sailor, thirty-seven years of age, was admitted with left hemiplegia, and paresis of right limbs. He died after a fortnight's stay in hospital, during which time he had some convulsive seizures, and some palsy of left third nerve. There was found softening of the anterior part of the left corpus striatum, with thrombosis of the anterior cerebral artery, and of a branch from that vessel supplying (in place of the middle cerebral) the softened part. On the anterior cerebral artery, close to the origin of the anterior communicating, was a small rounded nodule, the size of a pea, closely adherent to the wall of the artery, which it appeared to surround, but projecting upwards and forwards, and slightly compressing the left optic nerve, close to the chiasma. No sign of softening in ganglia or in other parts of right hemisphere.

Dr. HILTON FAGGE showed a recent specimen of Ulceration of the Larynx in Typhoid Fever. The patient was a sailor, twenty-three years of age, who was taken ill on board ship with enteric fever. There was a copious eruption of rose spots, diarrhœa, high temperature, and much bronchitis. His voice was hoarse and throat sore, and latterly he had had dysphagia. In the intestines there were only two small points of ecchymosis, as if from recent ulceration, in the ileum, and Peyer's patches were indistinct. The mesenteric glands, however, were all red and swollen. The spleen was not enlarged and was firm. The lungs were emphysematous, but not engorged. There was extensive laryngeal mischief, the right arytenoid cartilage being exposed by a deep ulcer containing unhealthy pus; there was also linear ulceration on each vocal cord and along the margin of the epiglottis. The gall-bladder contained no bile, only a thin mucous fluid, while the cystic duct was free from bile-staining. Dr. Fagge remarked upon the extensive amount of ulceration in the larynx and the slight degree of intestinal disease, the latter in strong contrast with the considerable extent of the change in the mesenteric glands. The absence of bile in the gall-bladder in cases of fever might, he thought, be explained by the patient's being fed at small intervals, so that, there being a constant need for bile, the function of the gall-bladder was superseded.

Dr. COUPLAND brought forward recent specimens of Organs from a case of Infantile Syphilis. They comprised the liver, heart, and lung from an infant three months of age, who was brought to hospital moribund, having been in good health to within three hours of death. At the autopsy there was found general interstitial myocarditis, the heart being square-shaped, its walls thick, firm, and very pale. A large gummatous tumour occupied nearly the whole of the left lobe of the liver, and extended for three inches into the right lobe; other nodules also existed on the liver. The mass was of a yellow colour, firm, and semi-translucent; no capsular thickening. In the right lung was a similar firm yellow nodule, the size of a large pea. Dr. Coupland remarked upon the interest of the case. 1st. From the mode of death and the widespread visceral disease, without interference with the health of the child, which was plump and well nourished. 2nd. The existence of syphilitic infiltration of the heart, rare enough in adults, but much rarer in infantile syphilis. 3rd. The large size of the gumma in the liver, a diffuse cirrhotic change being the usual form of hepatic disease in congenital syphilis. He had made a preliminary microscopic examination, but, on the invitation of the President, he deferred a full account to the next meeting of the Society.

The meeting then adjourned.

OBSTETRICAL SOCIETY OF LONDON.

AT the meeting on Wednesday, October 6th, Dr. Playfair, Vice-president, in the chair, Edward Chaffers, F.R.C.S. (Keighley), and Amos Rogers, L.R.C.P. Ed., were elected Fellows of the Society. Before entering upon the ordinary business of the evening, Dr. PLAYFAIR alluded to the loss sustained by the Society by the death of its honorary president, the late Sir Charles Locock, who had rendered valuable aid to the Society when it was first formed, by accepting the Presidency, and taking a special interest in furthering the aims of the Society. He announced that the unanimous feeling of the Council was in favour of asking Dr. Arthur Farre to accept the vacant post, which was received with acclamation by the Fellows present.

Dr. GERVIS exhibited a Pessary which had been removed from a patient fifty-six years of age. Fifteen years previously it had been introduced into the vagina to relieve prolapsus of the womb. Four years ago she began to feel a weakness in the lower back. Two years ago her legs became weak, and she was unable to walk without assistance. For six months she has been nearly bedridden. For the last six months she has had discharge from the vagina, occasionally tinged with blood, and highly offensive. She can neither stand nor walk, and is able to move her legs in bed with difficulty, being attacked two or three times during the night with cramp in them. On examination, a large round metallic pessary was found imbedded in the vaginal walls, and was removed by the aid of bone forceps, a considerable quantity of brownish purulent discharge, horribly offensive, escaping. All the paralytic symptoms were relieved after its removal.—Dr. CLEVELAND remarked that, apart from the interest attaching to the long impaction of a foreign body in the vagina, there was the notable fact that a quantity of highly offensive putrid matter must have been locked up for a considerable time without the supervention of septicæmia. The case tended to show, in connexion with the recent debate before the Society, the necessity for the co-existence of some peculiar condition of the general system before absorption of morbid matter, followed by blood-poisoning, could be effected.—Dr. BANTOCK had met with a similar case to that given by Dr. Gervis, the pessary being oval in shape, and composed of horsehair covered by india-rubber.—Dr. ROGERS referred to a case he had before mentioned to the Society, of a black boxwood pessary which had been left in eighteen years and had been forgotten by the patient.—Dr. EDIS also alluded to a similar case he had brought before the Society, where a large oval pessary, the size of a goose's egg, had been left in the vagina for eleven years, the case having been supposed to be cancer.—Dr. PLAYFAIR thought the archaic instruments would soon be out of use. Most of us had seen them. He wondered why the ulceration had not extended into the bladder and rectum. As regards Dr. Cleveland's remark, he (Dr. Playfair) had noticed that fetid matter of intense virulence might be present, provided there was an absence of an absorptive surface of a freshly formed wound.—Dr. GERVIS, in reply, stated that in removing the pessary a slight laceration took place. The fetid fluid passed over it, and yet there was no septicæmia.

Dr. HAYES exhibited a Placenta and Stillborn Fœtus from a patient aged twenty-two affected with syphilis. The placenta was pallid, soft, and friable, the villi packed with fat-globules. The fœtus appeared healthy. There were two questions involved in explanation of the death of the fœtus—whether it resulted from syphilis or from fatty degeneration of the placenta.

A report by Drs. Aveling and Hayes on Mr. Wallace's case of Monstrosity was read, as also on a specimen exhibited at a previous meeting.

A case of Complete Inversion of the Uterus, occurring immediately after labour, was communicated by Mr. FREDERICK H. GERVIS. The patient, aged forty-one, was delivered of her sixth child after a slow and tedious labour. The placenta was adherent. After waiting twenty minutes, it was felt projecting through the os, and was gently drawn down, when the uterus was found to be inverted. The placenta was immediately peeled off. The hæmorrhage was slight, but nevertheless the patient was found to be in a state of syncope, and apparently dying. Brandy and ammonia were administered, and after the patient had rallied somewhat, the inversion was reduced, counter-pressure being applied externally to the cervical ring. Galvanism was applied to contract the uterus after its return. The patient recovered perfectly.—Dr. GALTON remarked that the mode of reduction mentioned by the author, although successful in this case, was one hardly to be recommended for general adoption. The author described the reduction as effected by pressing two or three fingers up into the fundus of the uterus. This plan would necessitate the passage of four folds of uterine tissue through the os instead of two folds which would alone require to be passed through were the reduction accomplished by the more mechanically correct and usually recommended method of grasping the whole body and returning first the part latest in coming down.—Dr. GRIGG inquired whether there were any severe cramps and pains in the thighs as well as shock. He remembered a case in his own practice where the uterus came down with the greatest ease without any traction having been exerted.—Dr. BANTOCK thought the treatment was confirmed by the result. He did not agree with the preceding speaker (Dr. Galton) in thinking that the uterus was doubled up by pressing on the fundus, for we were told that the body of the uterus felt hard. It appeared to him that the reduction began at the cervix.—Mr. GERVIS explained that the uterus was exceedingly rigid and hard, and it was difficult to get a fold of the uterus. Whether the fundus or the cervix went up first he did not know. In a previous confinement she had had severe cramps.—Dr. CLEVELAND thought the whole question of inversion of the uterus of such an important character that he hoped he might be excused for inquiring more minutely as to the amount of traction on the cord that had been used. He could conceive that, owing to the administration of ergot before the expulsion of the placenta, especially if it happened to be adherent, the uterus might take on that irregular and spasmodic action which, with only moderate traction on the cord, might eventuate in inversion. He did not, however, for a moment doubt that Mr. Gervis would satisfactorily answer his question.—Dr. GERVIS remarked, with reference to Dr. Cleveland's suggestion as to the production of inversion, that so accurate an observer as Dr. Tyler Smith had in one instance seen the uterus invert itself, and it was now generally allowed that this accident could arise quite independently of traction. He would like to ask whether any Fellow present had ever seen the inverted uterus re-invert itself. He had read recently of such a case, but imagined it must be, at all events, an occurrence of extreme rarity.—Dr. HAYES observed that when we consider what difficulty sometimes occurs in getting the placenta away, the cord giving way first, it was scarcely probable that Mr. Gervis could have excited sufficient traction to produce the inversion.—Dr. AVELING remarked that inversion may be caused by *vis a tergo*, and even post mortem from the development of gas in the abdomen.—Dr. GRIGG mentioned a case occurring five days after labour where no ergot had been given.—Dr. ROGERS had only seen one case, which he replaced by means of an air pessary. He thought Mr. Gervis's plan was the best.—Dr. GERVIS referred to a case reported in one of the early volumes of the Transactions where the uterus had reinverted itself.—Dr. WILTSHIRE admired the courage and candour of Mr. Gervis in bringing forward his case. After fifteen years' experience in practice he would scarcely use immoderate traction; still the process of inversion might have been commenced before. It was a question whether it was not better to peel off and not to pull. We ought to be much indebted to Mr. Gervis for bringing the case forward.

Dr. GALABIN read a paper "On the Occurrence in Normal Labour of Lateral Obliquity of the Fœtal Head." After entering into the views formerly accepted that there is normally a lateral obliquity of the fœtal head to the plane of the pelvic brim, he asserted his belief that the conclusion indicated by theory is confirmed by observation—namely, that in easy labours there is no perceptible lateral obliquity, but that if the head meets with considerable resistance, an obliquity is produced in most cases of such a kind that the right parietal bone lies deepest in the plane of the brim.—Dr. Playfair thought the Society was very much indebted to Dr. Galabin for his erudite paper. The point at issue was one of great interest, and he had failed to satisfy himself whether Dr. Galabin's suggestions were sufficient. He (Dr. Galabin) had neglected to mention a very elaborate treatise on the subject by Dr. Hodge, who had given much attention to the subject.—Dr. Gervis quite concurred in all the President had said as to the value of Dr. Galabin's paper. It was, however, difficult to discuss such a paper without reading as well as listening to it. It would appear to favour the opinion that there was no necessary contradiction between the two opposite views, but that obliquity of the head, depending upon some undue pelvic resistance, was essentially a character of a labour in some degree abnormal, while in perfectly normal labour, the equilibrium between the propulsive force and the resistance of the parturient passages being, as Dr. Galabin expressed it, stable, obliquity did not occur. If further research proved this view accurate, it would account for much of the present dissonance of opinion.—Dr. Galabin thanked the Society for their patient attention.

Dr. J. Braxton Hicks read a paper "On a Dissection of a Uterus pregnant about three months and a half," the placenta being prævia, and fibroids extensively developed in the uterine walls. Attention was directed to three points:—1. Whether there were a circular sinus at the margin of the placenta? 2. The distribution of the curling arteries in the decidua serotina. 3. Whether there was any change induced by pregnancy in the fibroma. The first was doubtful, and is a point yet to be carefully examined. As regards the second, the decidual processes, consequently the separation into lobules, commence later than the third and a half month; there is no proof that any branch from the supplying vessels of the serotina passes into the intervillar space. As to the third point, the fibres were about four times larger than in the ordinary fibroma, very much more distinct and separable from one another. A few had attained the size of the colossal fibre of the ordinary pregnant uterus.—Dr. Edis observed that if the fibres in the fibroma increased during pregnancy, there was no reason why they should not equally be involved in the process of involution following parturition, the same as with the ordinary uterine fibres.

MEDICAL SOCIETY OF LONDON.

This Society commenced its session by a meeting on the 18th inst., Dr. Routh, President, in the chair. There was a large attendance of the Fellows and their friends.

Mr. Henry Smith exhibited a young man on whom he had successfully operated by Sir W. Fergusson's method for a Cleft in the Hard and Soft Palates. After a few congratulatory remarks by Mr. Bryant and Mr. Oakley Coles, the latter gentleman having made an artificial palate for a patient some years ago, where he imagined surgical interference impossible,

The President read a paper "On Hyperpyrexia," viewed especially in its surgical aspects. After a few preliminary remarks, five cases were given, two fatal, and three in which recovery took place. The fatal cases were one of ovariotomy and one of menorrhagia. In the latter a large and three small intra-uterine polypi were removed, and subsequently the case was complicated by the formation of a clot in the heart. The non-fatal cases comprised two of fibroid of the uterus, in one of which the galvanic cautery was applied, and in the other gastrotomy was performed; and one of menorrhagia, in which an abscess at last formed between the rectum and the vagina. These cases were illustrated by charts showing the high temperature attained in the axilla, the mouth, and the vagina; and Dr. Routh entered fully into the methods of treatment employed, strongly advocating and demonstrating the efficacy of the use of the ice-cold bath to reduce temperature, as deduced from the careful study of the above cases.—An animated discussion took place, in which Mr. Maunder, Dr. Thudichum, Dr. Rogers, Dr. Day, Dr. Broadbent, Dr. Theodore Williams, Mr. Jabez Hogg, and Dr. Evans took part, the speakers, with the exception of Dr. Thudichum, all concurring in the President's views.—After Dr. Routh had said a few words in reply, the meeting adjourned.

Reviews and Notices of Books.

The Journal of Anatomy and Physiology. Conducted by Professors Humphry, Turner, Foster, and Rutherford. Vol. X., Part 1. October, 1875. pp. 222. London: Macmillan and Co.

The present part of this valuable periodical is issued, as our readers will see, under new management, the Professors of Anatomy in Cambridge and Edinburgh having associated with them the Prælector of Physiology in Cambridge, and the Professor of the Institutes of Medicine in Edinburgh. As the only journal in this country purely devoted to biological science, it should receive the support of all workers in this country. Amongst other papers, all of which are interesting, the following may be particularly noticed:—1. "On the Primary Vascular Dilatation in Acute Inflammation," by Francis Darwin. In this the author describes the effects observed in the early stages of inflammation, and maintains, in accordance with the view which is supported by Schiff, Vulpian, and others, that the primary dilatation and secondary contraction are due, not to any direct action upon the vessels of the stimulants used to excite inflammation, but to the action of the agent on the vaso-motor nerves. These, however, include both inhibitory and constrictor fibres, and the condition of the vessel at any moment depends on the preponderating influence of one or other of these sets of vessels. 2. Mr. F. M. Balfour gives an account of the Origin and History of the Urino-genital Organs of Vertebrates, which throws much new light on the complicated questions of the origin of the kidneys, testes, and ovaries, and of the oviducts, vasa deferentia, and ureters. This paper is particularly fully and interestingly worked up, and contains the results of much personal observation. 3. Dr. Ogston communicates the results of his observations on Articular Cartilage, which are illustrated by six plates; and shows that the articular cartilages, on the one hand, are being constantly worn down and as constantly renewed on the surfaces which play upon each other; and, on the other hand, are constantly producing new bone to replace the losses, resulting from pressure on the spongy tissue of the articular extremities. This new bone is developed from the ossification of medullary substance, which is in its turn derived from the original cell columns of the cartilage. Dr. Ogston then proceeds to consider the changes that occur in cartilage under pathological conditions, in which he takes occasion to notice that the views of Cohnheim and others on the changes occurring in inflammation, however widely applicable they may be to vascular structures, have little or no bearing on this process in cartilage, and that we are in some danger of ignoring the minute investigations of Goodsir and Virchow on cell-growth. The changes in scrofulous arthritis and chronic rheumatic arthritis are succinctly given. 4. A second paper on Hyaline Cartilage is contributed by Mr. E. Baber, which is chiefly occupied with the consideration of the possibility of effecting artificial fibrillation in it by the action of reagents. Mr. Baber concludes that such fibrillation can be effected. 5. An account of the Brain and Cranial Nerves, with notes of some of the Viscera, of the rare shark Echinorhinus spinosus, by H. Jackson and Bruce Clarke. 6. Professor Turner gives the substance of the three lectures delivered in the College of Surgeons in June last, which have already been reported in The Lancet. 7. Professor Rutherford describes the Freezing Microtome, a most useful addition to the physiological laboratory. Lastly, Mr. Langley describes the action of Jaborandi on the Heart. Dr. Stirling writes the Report on Physiology, and gives an account of a new method of preparing the skin for histological examination.

Gazzetta Medica di Roma, diretta dal Dottore Filippo Cerasi. Si pubblica da Ermanno Loescher, Roma. 1875.

Last summer the physicians and surgeons of Rome, whether attached to the medical schools or devoted to consulting practice, established a medical academy, the programme and first proceedings of which we noticed in The Lancet. The movement, however, for a corporate organisation of the medical work of the city and province could not be regarded as complete without the periodical publication of its results, and accordingly a journal was proposed, and has finally taken shape in the *Gazzetta Medica di Roma.*

The editor bears a name familiar to the world of medicine, and he has had small difficulty in forming a staff of efficient coadjutors. In his introductory remarks he promises a complete survey of the medical field, with an eye, however, to practice rather than theory. The inductive method will be rigorously observed in the recorded investigations, and, naturally enough, these will be contributed from Italian in preference to foreign sources. The discussions of the Roman Academy of Medicine will be fully reported, and reviews of the latest medical literature will keep the reader informed as to the progress of the healing art at home and abroad.

The contents of the first number include an original memoir by the editor, entitled "Physiological Experiments and Clinical Notes on the Polycarpus pinnatus, or so-called Jaborandi," in which he comes to the following conclusions:—1. That the jaborandi of Continho has an elective action on the salivary glands. 2. That it has a secondary action, but less constant and copious, upon the sudoriparous glands. 3. That it has a well-marked diuretic action. 4. That it produces no effect whatever on the circulation, nor on the generation of heat, nor (except in an unimportant degree) on the respiration. 5. That its action is most efficacious when it is injected into the veins. 6. That its after-effects are distinct debility, with an imperious thirst, directly proportioned to the action of the emunctories. These effects, however, are transitory, and soon disappear under restorative diet. This paper is followed by a surgical one from the competent pen of Dr. Filippo Scalzi, of the Ospedale della Consolazione; and that again by a series of well-chosen extracts from other Italian journals, and from the publications of French, German, English, and American schools—The Lancet being laid under special contribution. We wish our Roman contemporary all the success which may be anticipated from its highly promising start.

Quarterly Journal of Microscopical Science. Edited by Dr. Payne and Messrs. Lankester and Thiselton Dyer. No. LX. 1875.

This part contains several excellent papers. The first is by Mr. D. J. Hamilton, on Myelitis, in which he describes the best mode of preparing the cord for examination, and then proceeds to show that in various cases he examined the axis-cylinders had undergone profound alterations, apparently into myelin masses, whilst the cells were converted into molecular masses, which at a subsequent period underwent absorption. The neuroglia was less altered; the bloodvessels had given way, and blood was extravasated. 2. Dr. Macnab gives an abridged translation of Oscar Brefeld's account of the Life History of Penicillium, the most common of moulds. 3. Mr. Worthington Smith describes the resting spores of Peronospora infestans, the fungus causing the potato disease. 4. Dr. Klein gives a description of the Structure of the Spleen, which differs in many points from those of his predecessors. He finds muscular tissue in many of the trabeculæ. He misses the reticulum as generally described, and finds instead a honeycomb of membranes, which only when seen in profile have the appearance of fibres. He thinks the pulp-cells are nucleated buds of the general matrix, and are gradually separated to form lymphoid corpuscles, which are finally carried away by the blood-current. He supports Kölliker's statements in regard to the presence of peculiar multinuclear cells, and he holds, with W. Müller and Frey, that the venous radicles represent merely a labyrinth of spaces in the splenic parenchyma. 5. Dr. C. H. Golding Bird describes and figures a differential warm stage for the microscope of ingenious and useful construction. 6. Mr. Poole gives the details of a mode of double staining with hæmatoxylin and anilin. 7. Mr. J. McCarthy contributes some remarks on Spinal Ganglia and Nerve-fibres. 8. Dr. Klein supplies a note on a Pink-coloured Spirillum, obtained from the fæcal discharges of a patient suffering from enteric fever. Lastly, Mr. Darwin adds an interesting note on the Structure of the Proboscis of Ophideres fullonica, an orange-sucking moth. There is the usual Quarterly Chronicle of Microscopical Science, Proceedings of Microscopical Societies, &c.

STATE MEDICINE EXAMINATION AT CAMBRIDGE.

A list of the successful candidates at the late examination in State Medicine at Cambridge has just been published, and in which we notice the names of the following medical officers of health:—P. Hinckes Bird, F.R.C.S., of Blackpool, Fleetwood, Lytham, and Poulton; T. Britton, M.D., of Halifax; S. Drew, M.D., of Wortley, Sheffield; G. H. Fosbroke, M.R.C.S., of the Rural and Urban Districts of Stratford-on-Avon, Evesham, and Alcester; C. Harrison, M.D., of Lincoln City and Rural District; S. T. Steele, L.R.C.P.E., of Todmorden Urban and Rural Districts, &c.; G. Turner, L.R.C.P.L., of Portsmouth; and A. S. Underhill, M.B., C.M., of Tipton Urban District, Staffordshire. The list also includes the names of A. Carpenter, M.D., J. Cunningham, C.M., A. Dunlop, M.D., B. N. Earle, M.B., W. M'Beath, M.D., H. H. Mason, M.R.C.S., J. Morison, M.D., E. Nicholson, M.R.C.S., H. H. Phillips, M.D., C. E. Saunders, M.D., and E. H. W. Swete, M.D., some of whom have, we believe, obtained appointments as medical officers of health since the beginning of the year.

The list of successful candidates in the examination above referred to was signed by G. E. Paget, A. W. Barclay, E. A. Parkes, and James Dewar, examiners.

Dr. Parkes was unfortunately unable to be present owing to an attack of sciatica, but we believe we are right in saying that the papers of candidates were forwarded to him. It must be gratifying to the University that its certificate has been sought by so many practitioners of credit in different parts of the country. We are able to say that much of the work of the candidates in the examination was very good, and that some of it was admirable. The "sanitary reports" were particularly good, and the great majority of them excellent.

The appearance of this list is most opportune at a time when Dr. Buchanan's address, delivered before the Association of Medical Officers of Health on Saturday last, has directed public and professional attention to the necessity for scientific qualifications in efficient medical officers of health.

The next examination in State Medicine at Cambridge will begin on Tuesday, June 13th. Any person whose name is on the Medical Register of the United Kingdom may present himself for it, provided he is twenty-four years of age. Information respecting the examination may be obtained by application to Professor Liveing, Cambridge.

THE LANCET.

LONDON: SATURDAY, OCTOBER 23, 1875.

Quite recently there have been in London several manifestations of a revival of the interest taken in Antiseptic Surgery. This is due partly to the powerful influence exerted by Mr. Lister's excellent articles on the recent improvements in the details of the system, and partly to the cogency of the appeals to facts made by Mr. Lister during the meetings of the British Medical Association; for it must be confessed that the demonstrations of antiseptic surgery to which we have so frequently referred, and a detailed account of which we published at the time, were both brilliant and highly satisfactory, even though they failed to convince many of the absolute indispensability of all the details of the plan. But this is a condition that the believers in the antiseptic system are apparently quite incapable of understanding. They are unable or unwilling to imagine that an observer of the antiseptic plan of dressing wounds may be perfectly satisfied with the results, though he may entirely repudiate the theory on which the method is based, or place little faith in the necessity of adopting every minute detail in the practical application. Happily, it is no part of the business of the clinical surgeon to bolster up theories, be they good or bad, or to make facts rigidly conform to them. The germ theory may be perfectly well founded; but nine surgeons out of ten do not care much whether it is or not, so long as they cure their cases and reduce their mortality to the lowest possible degree. Mr. Lister tells us that the air is, as it were, darkened with disease-producing germs; and that if we would ensure success we must destroy, not only all the germs in the atmosphere surrounding a wound, but also those that may have found their way into its recesses. Having thus secured an aseptic condition of the part, our care must, he states, henceforth be to preserve it so, by enveloping it with some antiseptic material. And it is on these grounds that he maintains every detail, from the spray producer to the aseptic instruments, is absolutely essential. But it is also on these grounds that his opponents join issue with him. They affirm, and the experience of most persons seems to bear them out, that they have seen cases do perfectly well, notwithstanding the freest admission of ordinary air with its accompanying germs, and where nothing but simple water has been used as a dressing. They urge, therefore, and not without some show of reason, that if all that Mr. Lister and his disciples allege be true, the successes, by no means unenviable, of the older surgeons must be looked upon as inexplicable phenomena—remarkable exceptions, especially as the sanitary condition of hospitals in those days was, as a rule, much inferior to that of modern hospitals. Less attention was paid to the personal hygiene of the patient, and certainly less care was exercised by surgeons, dressers, and nurses to prevent the introduction of organic poisons from the post-mortem room, the dissecting-room, or elsewhere, by means of the fingers, clothes, sponges, or dressings. If the antiseptic theory be true, how shall we account for the great success that, even in the present day, attends the practice of many surgeons who are well known never to employ the antiseptic mode of dressing? What explanation, for example, can be offered of Professor Spence's results in the Edinburgh Infirmary, the same institution, be it observed, in which Mr. Lister has had most of his triumphs? In his Address on Surgery, Mr. Spence stated that he had had, during three years, sixty-three major amputations for disease, with only three deaths, or 4·76 per cent.; and twenty-three cases of excision of the joints, with only two deaths, or about 8·7 per cent. These results were obtained "at a time when the treatment consisted in thoroughly cleansing the cut surface by pouring tepid water over it, and occasionally applying tincture of iodine, alone or diluted, on the flaps; whilst the dressing consisted merely in laying a veil of lint or thin muslin over the stumps." In addition to these numbers, two successful cases of amputation through the hip-joint for disease, recently performed by Mr. Spence, are this week recorded in the "Mirror of Hospital Practice," making in all sixty-five cases of major amputation, with only three deaths, or about 4·5 per cent.; whilst the average mortality in four metropolitan hospitals for major amputations for disease is, according to Mr. Erichsen, 27·4 per cent., and in University College Hospital 18·1 per cent., for forty-four cases. We have expressly taken Professor Spence's statistics as being exceptionally useful for purposes of comparison, the cases having been treated in the same institution at the same time that Mr. Lister was improving and elaborating his antiseptic plan. With such facts before us, surely we cannot be regarded as captious or unreasonable if we press Mr. Lister to declare, by means of statistics, his average success during the same period of three years. Has he had a lower mortality than 4·5 per cent. for major amputations for disease? But if he would make his case good, if he would justify the adoption of all the tedious and complicated details of his system, he must show even a lower mortality than that which has followed the employment of tepid water and thin muslin dressing.

This leads us to consider another important phase of this question. It is too commonly lost sight of that, since the late Sir Jas. Simpson sounded the alarm against large hospitals, special attention has been paid to the condition of general hospitals, and a widespread effort has been made to improve as far as possible the sanitary state of all the departments, but more especially the surgical. No precaution is now considered too trivial, and everything calculated to increase the healthiness of hospital wards or enhance the prospects of recovery is carefully attended to. Curiously enough, the antiseptic system has been contemporaneous with these improvements in the general management of hospitals, and it is more than probable that much of the credit due to increased care and cleanliness has been accorded to the antiseptic plan of dressing wounds. This statement is borne out by the fact that the antiseptic system has perhaps had its warmest advocates on the Continent. The eulogiums of some of the continental hospital surgeons have been extravagant. But no one acquainted with the filthy and neglected condition of many of the continental hospitals fifteen or twenty years ago, and even more recently than that, will be at a loss to understand why the mortality in these hospitals has so greatly diminished since the introduction of antiseptic surgery. Even the moderate use of clean water and the observance of the ordinary habits of personal cleanliness would have sufficed to reduce very considerably the frightful mortality in them. The testimony in favour of the antiseptic system given by surgeons who had hitherto been accustomed to an average mortality of 60 to 70 per cent. after surgical operations is not therefore of much special value, except so far as it shows what may really be done by attending to the ordinary rules of practical surgery.

There is yet another question which we trust will be thoroughly ventilated at this (Friday) evening's discussion on the antiseptic method at the Clinical Society. We refer to the employment of the drainage-tube. Experience has shown that the employment of the drainage-tube, first systematically recommended by Chassaignac, exercises a great influence on the progress of a case treated antiseptically. In fact, the drainage-tube has now come to be regarded almost as essential to success as the antiseptic preparations themselves. It remains to be proved what share the drainage-tube has in the success of the antiseptic system.

If the Clinical Society's discussion elicits answers to the following questions, it will serve a useful purpose:—Are the results of the antiseptic system better than those obtainable by other means? If they are better, are all the details in carrying out the method which are regarded as essential to success really necessary? If not, which may be safely dispensed with? What share has the employment of drainage-tubes in the success? And how much may be attributed to the extreme care, attention, and cleanliness that the antiseptic system imperatively demands?

◆

PERHAPS no derangement of organic function which finds no place in our text-books of the principles and practice of medicine causes a greater amount of suffering, and is more often a source of real danger to health and life, than sea-sickness. Perhaps also none, whether in or out of our text-books, has baffled more completely the best efforts of therapeutical science—efforts which have been practically, if not absolutely, without result. Old remedies have been tried and tried again. New remedies and new modes of administration have been employed, with little better result. Chloral, indeed, first suggested for the purpose by BODO and DÖRING, gives a certain degree of immunity from the unpleasant malady, but it is only by means of narcosis. Other methods of treatment have been useless or impracticable. Neither drugs nor other medicaments, hypodermic injections, ice to the back or faradisation to the front, have yielded results sufficiently satisfactory to suggest further employment. So at last the engineer has to step in, while we stand by and watch. Nor is the arrangement altogether an unreasonable one. It is but fair that it should be the office of mechanical science to prevent the evil of which mechanical force is the cause. And the success of the attempt is apparently considerable. The testimony of those who have taken part in a recent discussion of the subject, especially the letter of Mr. MARSHALL, leaves little doubt of this; and we may congratulate the projector of the *Castalia* in having shown the way in which, by physical means, the physical evil may be materially lessened.

Of more direct interest to us is the incidental discussion, to which the success of the *Castalia* has given rise, concerning the mechanism by which sea-sickness is produced. The statements on the subject by Mr. MARSHALL, Dr. P. BLACK, and Dr. CLAYE SHAW in *The Times*, and by Dr. WILKS in our own columns, show how much we have yet to learn before we can congratulate ourselves on understanding the effect of the peculiar motion of a ship upon the human frame. Respecting the remote cause of sea-sickness there is indeed a consensus of opinion. It is the vertical movement of the body which is the chief instrument in its production. Mr. MARSHALL pointed this out clearly in *The Times*, but it has always been the popular impression. In every movement of a ship at sea of which a person on board is sensible the upward and downward movements enter; every movement therefore may act as a cause of sea-sickness. The prevalent motion varies with the relation of the waves to the ship's direction, and with their size. The place of least motion in a ship will vary according to the direction of motion. A study of this is important to the indifferent sailor. Places are often chosen as the least exposed to risk which, though best in one form of movement, are worst in another. In a moderately rough sea, when the movement is a "pitch,"—an antero-posterior oscillation on the transverse axis of the ship,—the nearer to that axis the less is the motion, and there is far less on the bridge than at either end of the vessel. When the waves are larger, and a vertical lift and fall of the vessel is combined with the oscillation, vertical lift movement is felt equally in every place. It is a movement which can only be overcome by having a vessel disproportionately larger than the waves. The roll is (approximately) on the antero-posterior axis of the ship. The nearer to that axis the less the motion, and the bridge, which is furthest from that position, is the least quiet position.

It appears unquestionable, also, that the effect of the vertical motion in producing sea-sickness is related, to a certain extent, to the vertical position of the body. Sea-sickness is induced in the horizontal posture less readily than in the vertical. But it *is* produced in the horizontal position, and therefore no absolute effect can be attributed to posture. Moreover, many animals are readily made sea-sick the posture of which is not vertical. An elephant crossing between Boulogne and Folkestone the other day was fearfully distressed, and dogs are not unfrequently sick when crossing the Channel.

Exclusive stress must not, however, be laid on the vertical direction of the motion, because it is impossible to separate sea-sickness from other similar disturbances of nervous and gastric functions which occur in susceptible persons in other conditions. The most familiar example of this is the effect of the motion of a carriage when riding with the back in the direction of movement, to which Dr. WILKS has alluded.

On what organ the cause of sea-sickness primarily acts is still in dispute. The symptoms are those of both nervous and gastric disturbance, and are of such a character, as regards both brain and stomach, as might well result from the influence of the primary disturbance of the function of either. Accordingly the brain and the spinal cord, the stomach and the solar plexus, have each been supposed to be the susceptible spot on which the motion acts. Plausible reasons have been given for assigning to each the chief passive influence in the production of sea-sickness. Perhaps the abdominal viscera are those to which the balance of authority has pointed as most probably the organs primarily disturbed. The chief symptoms are those of gastric disturbance; the nervous symptoms are such as may well be secondary. Intense nausea, malaise, and vomiting point distinctly to disturbance of gastric function. The evidences of primary nervous derangement are not conspicuous. Sensations of discomfort referred to the head are common: headache, more or less severe, is an occasional coincident or subsequent trouble. But any more distinct evidences of brain disturbance are absent. Loss of consciousness hardly ever occurs; and loss of consciousness is a very frequent concomitant of vomiting from cerebral disturbance, especially when the cause of disturbance acts suddenly. Symptoms of spinal disturbance are likewise "conspicuously absent."

On the other hand, it is much easier to understand how a new mode of motion may affect the nerve-centres than the alimentary viscera. The sensory centres—so sensitive to every displacement, to every sudden change of circumstances and of position, so easily influenced by external impressions, whatever be the avenue through which those impressions act—may be more easily conceived to be affected by an unusual and repeated displacement than the viscera of vegetative life. There have, accordingly, been many explanations of sea-sickness founded on supposed primary disturbance of the brain and spinal cord; but of these none has secured any authoritative corroboration except that of Dr. WOLLASTON. The theory, as our readers are probably aware, refers the symptoms to cerebral disturbance induced by the repeated mechanical congestion of the brain which the repeated downward movement of the ship induces. Every time the body descends to a lower level the *vis inertia* of the blood is supposed to be sufficient to determine a certain amount of cerebral congestion, and even, it has been intimated, of cerebral concussion, to which the symptoms have been referred as secondary. The excess of discomfort during the descending, as compared with the ascending, motion has been cited in support of the hypothesis. The explanation commends itself by its ingenuity, by its apparent accordance with the phenomena, and by its suggestion of a mechanism by which the mechanical is transformed into a vital disturbance. That the mechanism is one really at work is shown by the fact related by Dr. CLAYE SHAW, that bleeding at the nose came on during the descent of an incline, and recurred at each frequently repeated descent. It is evident that here the conditions of sea-sickness were all present. But the explanation of Dr. WOLLASTON is by no means conterminous with the facts. Other symptoms of cerebral congestion are wanting in the phenomena of sea-sickness; and, as Dr. MAYO has pointed out, there is a corresponding absence of the most distressing symptoms of sea-sickness among the phenomena of cerebral congestion or concussion. That the symptoms are more marked during the descent than during the rise of the vessel is but in accordance with their physical cause, however it acts; for when the vessel, as a whole, rises and falls, the fall will be always more sudden than the rise, inasmuch as the fall is the sum, while the rise is the difference, of the wave-motion and the effect of gravitation upon the vessel. Moreover, the explanation of WOLLASTON fails to throw any light on the sickness which results from other forms of motion, and which, if less intense, is so similar in character to that of sea-sickness. The difference between motion forwards and motion backwards cannot be referred to the effect on the cerebral circulation. The whole explanation of sickness, it seems to us, has yet to be given. Whatever it may be, it must afford an explanation of many facts which no theory yet offered accounts for. One of them, which no hypothesis adequately explains, is the effect upon the symptoms of sensory impressions. Every bad sailor knows how potent these are in aggravating his distress, and many moderate sailors know how useful they may be made in decreasing their discomfort. The nausea which, with the face to the bows, is trifling, may be increased to immediate vomiting by turning round into the opposite position for a few minutes. The motion in a swing, which is agreeable as long as the eyes are open and the movement watched, is changed to intense nausea as soon as the eyes are closed and the motion unforeseen. In a further stage of sea-sickness it is true the very foresight of the motion adds intensity to the distress; but this is only another aspect of the same fact of the influence of the senses, and all these circumstances of sensory effect must be taken into account in any satisfactory explanation of sea-sickness. It is probable, then, that the phenomenon may be found to be a complex one, in which many factors are at work, and to which many causes predispose. If so, we shall understand, and shall be able to contemplate with more complacency, our non-success in its treatment by drugs, and shall welcome without self-reproach the aid to human comfort the *Castalia* affords.

◆

THERE are two methods of relieving distress. You may intimate your willingness—or consent—to render assistance if applied to, throwing the onus of deciding when, and how often, to seek relief upon the applicant; or you may put yourself to the trouble of searching out the causes of embarrassment, inquiring into the extent and curability of the evil it is desired to remedy, and bringing your outside judgment, your friendly interest, as well as your means, to bear upon the case, with a view to a radical and complete amendment. In the first system you take up the position of a "resource," and must not be surprised if the poor form a habit of falling back upon you as a reserve in time of pressure or extremity. And, as you bear leaning upon, they will not unnaturally come to rely upon your aid continuously and to draw upon you repeatedly. In the other case you undertake the mission of an active protector, ready to "help"; and you have the opportunity, and a claim, to temper charity with judgment—to see that proper efforts are put forth to make the best possible use of the assistance rendered, and to minimise the drain upon resources actively employed not only to ameliorate poverty but to secure success. The Poor-law system of relief is modelled upon the principle of a resource—created by compulsion and maintained under pressure. It in no sense affects the principle of the method adopted that "relieving" officers are appointed to inquire into the actual poverty of persons seeking aid from the rates. This is only a precaution against imposture. The poor are left to struggle, starve, or sue out the succour they need, at their own discretion; and if anyone complains that they do not come soon enough to ward off the worst evils of penury, it is not their so-called "guardians," although, as might be expected under such a system, it commonly happens that in the long run the relief exacted costs more than it would otherwise, because it is too long postponed. Habitual and hereditary pauperism is probably, in large measure, the fruit of this method of grudging relief, which creates a resource, hedges it round with all sorts of scarecrow difficulties and precautions, and leaves the poor to fight out a claim and establish a settlement on its niggardly bounty. The evils of the system are especially strongly marked in its relations to the sick poor, and it is with this aspect of the subject we are more immediately concerned. It may be idle to hope that anything we can urge will avail to convince the Legislature of the exceeding rottenness of the whole system of the Poor Law, but there are certain powerful considerations which may be enforced as supplying a good and pressing reason why at least one fault of the existing *régime* should be speedily remedied.

As matters now stand it is impossible for district medical officers to do their duty with satisfaction to their own sense of humanity or in the real financial interest of the ratepayers. The proportion of paupers on the "permanent sick-list" is everywhere increasing. It is fed by the short-sighted parsimony that throws obstacles in the way of relief when maladies are in their earliest and remediable stages, and while constitutions are as yet unenfeebled by want and those accumulated small complaints which in the end make up an incurable condition and life-long helplessness and disease. The parish doctor looks round with dismay on the ruin wrought daily by a system against which he struggles in vain. It is not worth while to recount the well-known features of a prospect which is ever present to the medical officer under the Poor Law, and which every social reformer must recognise and deplore. To come at once to the remedy, we think it would be found in a well-organised *system of house-visitation*. It may be difficult, perhaps impossible, to change the principle of sick-relief in the country; but it would not be a task of surpassing difficulty to call into operation, side by side with the existing machinery, an effective system of personal sanitary and health inspection, coupled with such provisions for the treatment of incipient and chronic disease as might place the remedy on a basis of prevention and radical cure. The first step in this reform would be the formation of local committees, charged with the duty of house-to-house inspection, and armed with the power of placing cases requiring medical assistance under proper care. The recommendations of the medical officers charged with the treatment of these cases should be carried out, in the matter of "necessaries," physic, and medical appliances, without the intervention of the relieving officer—at least without the obstruction which this official, looking to the pecuniary code of his employers, the local board of guardians, is apt to offer. Patients should be treated at their homes, or in a convenient hospital. The "order" for the house that breaks up a *home* destroys the influences it is most needful to strengthen, and extinguishes the highest incentive to self-help. It is the instinctive dread of being pauperised which deters the struggling poor—those who by timely aid might be prevented becoming a permanent burden on the rates—from seeking medical assistance when it would be most serviceable. The cost of medical attendance, medical comforts and necessaries, should be defrayed from a central fund by the Local Government Board. The expenditure need not be excessive; it might be carefully supervised by proper auditors, and we are assured it would be found economical. The idea is no longer utopian, because the ice has been broken. A recent order of the Central Authority has given the registrars of births and deaths increased pay, the additional outlay being made up to the ratepayers by being included in the general estimates, and paid out of the Consolidated Fund. The objections of Bumbledom are thus avoided or reduced to their due insignificance. If the same principle were applied to the solution of the problem of bringing timely medical relief and assistance to the aid of the poor, the fruit would soon be apparent in a healthier population, a happier people, and less "habitual and hereditary pauperism"—the product of a system of *resource* which breeds dependence, and only to be eradicated by a system of active and efficient *help*, ministered when and wherever it is seen to be necessary, and with the set purpose of prevention, restoration, and permanent cure. To treat the sick poor as bread-winners temporarily disabled, not parasites, to give them the best help at the time when their maladies are susceptible of remedy, to cure them as speedily as possible, ought to be the governing maxims of a policy which aims to reduce the burden of pauper maintenance. A system under which these intentions become impracticable, and nothing but the most perfunctory discharge of professional and public duty is possible, must be one no conscientious medical officer can regard with complacency, and which the wisdom of an intelligent and far-sighted people should refuse to countenance.

◆

WHATEVER opinion may be entertained regarding the theories of the nature of Chorea which Dr. DICKINSON laid before the Medical and Chirurgical Society at its last meeting, his investigations into the pathological anatomy of the disease cannot but be regarded as a very important contribution to our knowledge of the morbid processes which underlie or accompany that mysterious disease. Mysterious it is from whatever aspect it is regarded; and so diverse is it in its associations that it seems almost hopeless to look for any theory which shall afford at once an intelligible and harmonious explanation of the varied conditions under which it arises, the strange associations of its course, and of its own remarkable characteristics. Certainly its difficulties, if lessened, are by no means cleared away by the discovery of widespread arterial mischief through the spinal cord and central ganglia, which was the chief result of Dr. DICKIN-

SON's researches. Periarterial erosions, distended arteries, effused blood, are traces of hyperæmia, which constitutes, according to him, the essential character of the disease. The irritation, by the vascular change, of the nervous tissue in which it is found, translates itself in the disordered movement which is the great symptom of the disease. The explanation of the multiform associations of chorea is to be found in the many sources from which such hyperæmia may, hypothetically, arise, and which Dr. DICKINSON would make as numerous as are the distinct clinical associations of the malady, grouping into the two categories of rheumatic and mental or reflex. He finds these changes and these conditions common to other maladies, and determined to a specific end by the coincident conditions of age or special circumstances which are recognised as predisposing causes.

There is nothing, we may remark, absolutely new in Dr. DICKINSON's discoveries. Similar changes were found in the spinal cord in two cases of chorea by Dr. LOCKHART CLARKE seven years ago. The extent and universality of the changes is a matter of the highest importance, and that Dr. DICKINSON has certainly shown. The state of hyperæmia of the nerve-centres accords well with many of the clinical facts of chorea: its frequently sudden onset, its febrile characters, its transitory course. But the association of that hyperæmia with the antecedents and concomitants of chorea is less easy to understand. The association with endocarditis is especially obscure. Dr. DICKINSON would find the explanation in a common rheumatic influence in one class of cases, and in another class he believes the endocarditis to be produced in an almost accidental manner, by the irregular action of the heart. That this latter can give rise to endocarditis is, however, an almost inconceivable proposition, unsupported by any pathological facts; and we cannot but agree with Dr. BROADBENT in rejecting it as an explanation of what is the greatest difficulty in the associations of chorea—the occurrence of endocarditis in cases of chorea of apparently mental origin. In estimating the relation of endocarditis to other maladies, we must remember that its existence cannot be always taken as synchronous with the duration of the signs by which we infer its presence. It may unquestionably exist without a murmur; and this fact, of which Dr. DICKINSON does not take sufficient count, is especially significant, since in hardly any of the fatal cases of chorea has endocarditis been absent. It may be fairly claimed by Dr. HUGHLINGS JACKSON as a reason, if not for the acceptance, yet against the rejection of the explanation of the association of the two conditions which he has so long advocated. Dr. BROADBENT differs from Dr. DICKINSON as to the seat of the malady, believing the central ganglia at the base of the brain to be the chief seat of the morbid process; and he apparently finds in the widespread character of the hyperæmic mischief ground for doubting how far that alone can be regarded as the essential morbid change. This opinion will be shared by many who have observed the remarkable absence of spinal symptoms. Hyperæmia, so widely spread as it appears to be—and from its supposed origin would naturally be,—can hardly be regarded as the only cause of a chorea of strictly local distribution. We are not surprised that Dr. HUGHLINGS JACKSON urged this fact as evidence in favour of a theory which, whatever be its difficulties, affords a better explanation than any other of the unilateral distribution of the affection in certain cases in which cardiac mischief coexists. He urged that none of the pathological facts adduced were really inconsistent with the embolic explanation, and pointed out, with much ingenuity, how well his theory harmonised with many of the hemiplegic resemblances of the unilateral affection. Many of these arguments, however, pointed only to the local nature of the primary change, and were equally applicable to any other morbid process having a local focus.

Whatever may be the fate of the views of chorea which were the subject of the discussion, they cannot fail to serve one great end of hypothesis in scientific progress. Whether right or wrong, whether destined to take their place among the admitted facts of medical science or to be consigned to the limbo of unfounded fancies, they will stimulate observation and incite study of the varied relations and characters of the affection, clinical and pathological. Much evidently remains to be done, even though much has been done; and among the latter the investigations of Dr. DICKINSON will occupy an important place.

◆

THERE is very much to be regretted, and much that ought to be quickly amended, in the practice of "coroners' courts" and "quest law." We have always insisted, and must still contend, that a searching inquiry into the circumstances and cause of *every* non-natural death is indispensable to the public safety and the common good. Apart from the obvious necessity for such a precaution against secret murder and manslaughter, there is the manifest need of searching out and bringing to light the insidious causes of death which grow out of our high civilisation, our pursuits, our artificial modes of life and intense activity. If there were no fear of intentional wrong-doing, the scientific obligation to prosecute a rigorous inquiry into every unexplained decease of human life would remain. Indeed, the class of cases to which that obligation applies is much the most important falling under the coroner's jurisdiction. The failure to recognise this circumstance lies at the root of all the idle talk about the superior fitness of lawyers for the coroner's office, and it is the cause of that short-sighted prejudice and false economy so strenuously opposed to post-mortem examinations. If the sole, or even the chief, mission of an inquest were to determine whether somebody ought to be prosecuted for killing or causing the death of a deceased person, we might be disposed to agree with those who believe that a lawyer is better qualified to discharge the function of criminal inquisitor than a medical man. But this is not the fact, and we must contend, as we have always argued, that a knowledge of pathology, and the cognate sciences comprehended under the term medicine, is essential to an adequate discharge of the duties devolving on a coroner. Meanwhile, this argument tells lamentably against the existing practice of nine courts in ten, and it bears powerfully upon the mode in which the evidence of experts in medicine is received, and digested in submitting a case to the jury—even by *medical* coroners.

It is painful to watch the continual waste of scientific testimony which the present slipshod practice entails.

The Medical Societies and the professional press do something to collect and collate the valuable data so wantonly cast aside; but the coroner's court, as a piece of constitutional machinery, is practically almost useless. Scarcely a week passes without the slurring over and neglect of some case fraught with lessons of priceless value. Cases of poisoning by agents and with symptoms not clearly defined or accurately recorded; cases of death from the secondary and remote effects of disease or injury not properly traced to their cause or adequately exposed and located; instances of misadventure, malpractice, or neglect left without scrutiny and unexplained,—these are the tares that mar the harvest of information to be gleaned from a court of inquiry properly conducted and duly reported. Can nothing be done to remove a standing and mischievous reproach? Will not some medical coroner devise and inaugurate a scientific code of practice covering the needs we have tried to indicate? It would not, surely, be difficult to lay down some general outline of a method of inquiry and report to which medical evidence might be required to conform. There are systems of pathological research which would form the model for a simple but comprehensive and efficient method of investigating the "cause of death." If medical witnesses clearly understood the kind of questions they would be required to answer at an inquest, and if the "opinion" demanded from them were logically worked out by these questions, the quality of "medical evidence" generally would improve, and, instead of being uninteresting and—for medical purposes—valueless, it would come to be prized by the profession as a calm and accurate account of the symptoms and appearances associated with particular kinds of death, and therefore instructive and practically useful. The reform we suggest is within the scope of any coroner having a tolerably extensive district under his jurisdiction. That the task will call for courage and independence there can be no question. The immediate effect of a resolve to treat the subject of medical evidence on scientific principles, and to make the inquest a reality instead of a farce, must be a strong and clear assertion of the fact that post-mortem examination is absolutely essential to the discovery of truth in *every* case of unexplained death, and in many cases also where the cause is tolerably clear. This position will need to be taken up in disregard of the rule of economy which boards of magistrates are everywhere enforcing. Nevertheless the enterprise is a worthy one, and we trust that some spirited medical coroner will recognise the claims of his profession, and commence the good work in dignified indifference to personal consequences, and without delay.

JUDGING from an article in a local paper on the vital statistics of Hull, we should say the presence of one of the Local Government Board medical inspectors is required in the town. In one district of the town the death-rate lately reached the figure of 44 per 1000 annually. It is alleged that "the pestilential effluvia of the now celebrated manure works" are responsible for the special mortality in this particular district. The sanitary authorities are charged with grave neglect of duty, or, as our contemporary strongly puts it, "the people of Hull are being poisoned with stench by the connivance, if not with the actual co-operation, of the local sanitary authorities."

Annotations.

"Ne quid nimis."

DUCHENNE.

WHEN the day comes in which medical workers of the present generation can be regarded in the perspective of the past, perhaps no figure will stand up so conspicuously among the rest as that of him whose body was lately laid in his native town, towards which he had turned, his life through, with such warm affection. Duchenne "de Boulogne" has written his name among the clinical facts of medical science in indelible characters, and in his own special qualities his form will always tower distinct among his contemporaries. No field of work was ever seized upon with more eagerness, ever cultivated with more earnestness, or perhaps ever made to yield a better harvest, than that which the discovery of induced electricity placed at the disposal of the man whose genius should first recognise and talents secure the opportunity it afforded. The new means of investigation which faradisation presented were prosecuted by Duchenne in every direction. Dark places in physiology and pathology were made plain, and the advance which each science received was real and considerable. Almost the whole of the muscular system of the body was brought by him within the range of experimental observation, and both the mode and form of its function were investigated and illustrated by a method of unrivalled clearness and unsurpassed accuracy. It is not surprising that a key was found to undo more than one hitherto closed, and even unsuspected, door in clinical pathology, and the result has been the distinctive definition of more separable forms of disease than have been discovered by any other investigator of the present century. The credit of discovery can hardly be denied to Duchenne, even in the cases in which he had been, unknown to him, anticipated, as was undoubtedly the case with regard to locomotor ataxy. In labio-glosso-laryngeal paralysis, and in pseudo-hypertrophic paralysis, the palm of first description belongs more clearly to him. His mind, indeed, was hardly less precise in its action, less comprehensive in its grasp, less secure in its results, than the agency which he employed. His energy was inexhaustible. Fed by an unfailing spring of enthusiastic love for his work, it carried him successfully over obstacles which would have arrested many workers of inferior force. No pains were too great that were necessary for the full investigation of a case in the most laborious manner; no time or trouble too much to secure accuracy of detail and result. No one who had witnessed his demonstrations of pathological or physiological fact could fail to be struck with the remarkable care and quickness, but, withal, painstaking precision, with which he worked. Somewhat profuse in description, his utterance had that sharp emphasis which, as it were, italicised the salient points of his discourse. A rather quaint mannerism marked his delivery, which was accompanied with the demonstrativeness of style so common to his nation, and which he possessed, perhaps, in less degree, but to a greater extent, than most. Few will forget the quiet explosive "Bon!" with which he used to announce a satisfactory result of his experiment.

As a writer he was clear and precise. Perhaps, indeed, his love of precision sometimes carried him into unwarranted antithesis. His style of description was graphic, but, to an English reader, diffuse and a little tedious, especially when drawn on, by the attraction of past polemics, to "fight his battles o'er again." While not perhaps naturally pugnacious, Duchenne was, in early life at least, jealous of encroachments on his own special province, and was certainly not disposed to accept new light from whatever quarter it might come to him. His position in his great controversy with Remak, concerning the constant current, cannot be altogether admired. But for much of this he atoned in later life. Even the despised "constant current" he adopted into his repertory, and one of his latest *brochures* was concerning its employment in a form of muscular over-action. Nothing, too, can be more admirable than his readiness to reconsider the most cherished pathological conclusions which he had based upon his therapeutical results, and indeed the character of those therapeutical results themselves, in the light of modern discoveries in the minute anatomy and pathology of the nervous system. For the researches of Lockhart Clarke he had an unbounded admiration, and some of his latest labours were devoted to a not very successful attempt to secure by photography permanent records of these and other investigations.

Taking his work at its lowest estimate, he was a man to whom medical science owes a large debt of gratitude, and whose memory deserves a warm tribute of regard.

THE SALE OF FOOD AND DRUGS ACT.

A CIRCULAR official note has recently been issued from the Local Government Board to county authorities drawing attention to this Act, summarising the material amendments and generally explaining its provisions. We have already reviewed the Act in detail, and the authorities at Whitehall take great credit to themselves in having presumably simplified as well as condensed the law on adulteration. The circular recites that the Act as it now stands protects the seller—(1) by permitting those practices in the established usage of trade with respect to the addition of harmless ingredients not intended fraudulently to increase the bulk or weight of the article or to conceal its inferior quality, which clearly ought not to constitute an offence; (2) by enabling him to protect himself in the case of a mixed article by affixing a label to it; (3) by giving him the right, when he has a written warranty, to plead the warranty as a defence; (4) by providing that, if convicted, he may, in an action against the wholesale vendor for breach of contract, recover the costs of his conviction, if he proves that the article was sold to him as being of the same nature, substance, and quality as that demanded of him, that he purchased it not knowing it to be otherwise, and that he afterwards sold it in the same state; (5) by requiring the purchaser, when he intends to have the article analysed, to divide the sample, and leave one part with the seller; (6) by providing that in the case of tea it shall be examined by officers of Customs at the port of landing; (7) by enabling the seller and his wife to be examined as witnesses on his behalf; (8) by authorising the justices, where the result of the analysis is questioned, to have the article referred for analysis to the laboratory at Somerset House. And it is declared to protect the interests of the public—(1) by protecting the purchaser against the delivery of any article which differs in substance, nature, or quality from the one demanded; (2) by punishing the seller who abstracts any part of an article so as injuriously to affect its quality; (3) by preventing the sale of articles mixed with ingredients not in accordance with that demanded by the purchaser, without a label indicating that they are mixed; (4) by enabling medical officers of health and police constables, in addition to the inspecters authorised by the former law, to obtain articles and submit them for analysis when directed to do so; (5) by assisting the local authority of a small district to obtain the services of an efficient analyst by empowering them to engage the analyst of another authority, and by enabling a purchaser in a district where there is no analyst to obtain analyses from the analyst of another district; (6) by compelling the trader to sell a sample for analysis on demand; and (7) by rendering the law more intelligible, and therefore more practicable, accessible, and certain. We commend those interested (and who is not?) "unto this last" advantage, and trust that this enactment may be fully intelligible to the community. The above-detailed advantages appear to us to be on the side of the seller. Be this as it may, we prophesy again that one practical result of the Act will be to give the laboratory officials at Somerset House plenty of work to do.

ENTERIC FEVER ON BOARD THE "CORNWALL" SCHOOL-SHIP.

DURING the past week six fresh cases of enteric fever have been admitted into the Seamen's Hospital from the *Cornwall* school-ship. This makes the number of cases admitted during the last three weeks 26. Besides these, there are 28 cases treated in a temporary hospital on shore near the ship. So that the total number of cases suffering from fever amounts to 54, out of a crew of nearly 200. The cases admitted at the Seamen's Hospital are nearly all progressing favourably. There is only one case about which any anxiety is felt. The chief complication has been pneumonia, and in one case there has been severe cerebro-spinal symptoms. Some cases of simple pneumonia have been sent from other training-ships on the river to the Seamen's Hospital, and this fact is interesting in connexion with the outbreak on board the *Cornwall*. We are this week enabled to give a brief summary of a report that has been submitted to the authorities of the school-ship by Dr. Harry Leach, medical officer of health for the port, who was directed to this step by the Port Sanitary Committee of the Corporation.

In searching for the cause of the outbreak attention was, of course, directed to the water-supply. The ship is furnished with water from a main that proceeds from the Grays waterworks through the villages of Stifford, Warley, and Brentwood, to Purfleet, where at the end of the village a pipe branches off to the edge of the river, on what may be called the *Cornwall* wharf. There is no reservoir on this wharf, for the water has hitherto been delivered by means of a flexible hose directly over the bank into an open boat, which conveyed it in bulk from the shore to the ship, where it was pumped into the tanks. This open boat, when not in use, lay under the ship's side, exposed to leakage from without, any chance washings from above, and near to the outlets of the galley scupper, of one set of closets and of the sick-bay closet. And it is matter of common observation that at certain times a large amount of decomposing sewage from the metropolitan main drainage outfalls at Barking and Crossness is left on the banks by the ebb tide immediately opposite the ship. These conditions existing, it is no matter of wonder to find by analysis that the difference between the two samples of water, as obtained from the standpipe on shore and from the tanks on board the ship, is very great indeed, and very much to the disadvantage of the latter. And so, as we suggested in THE LANCET of the 9th, the proximate cause of the outbreak is clearly due to very distinct water contamination. Several other predisposing causes were found, but, as they are common to nearly all school-ships, we need not recapitulate them here, especially as they will be found in detail when the report is published. From notes taken by Mr. Glen Bott, of Aveley, surgeon to the ship, it appears that the first case was diagnosed by him on September 14th, was kept in the hospital of the ship for five or six days, and was then sent to the Seamen's Hospital at Greenwich. No further sickness occurred among the boys until the 2nd of the current month, when three cases were found and removed. On the following day two more occurred, and from this date the numbers increased rapidly. The direct connexion between the first case and those that occurred subsequently remains to be proved, although the indirect evidence is abundant. Among the victims is the carpenter of the ship, who became ill shortly after the commencement of the epidemic.

The principal remedy advised is the adoption of a direct water communication from the shore to the ship by means of a hose from the main to the tanks. There is no practical difficulty in this plan, which was adopted in the old *Dreadnought* many years before its disestablishment, and, with proper care, worked well. Meanwhile, it is recommended that tanks be used to convey the water instead of casks, as the former can be examined and cleansed much more effectually than the latter. Many minor suggestions, made by the health officer and the surgeon, have been already adopted.

This outbreak must necessarily show to all authorities connected with floating establishments the necessity, among other things, of obtaining and preserving a good supply of potable water. But in point of fact, as we have often before indicated, all school-ships and training-ships, whether receiving financial aid from the Government or not, should be under the supervision of the Board of Trade, and that Board, in conjunction with the Admiralty, should decline the use of the ship, or to allow her to be inhabited by boys, unless certain prescribed sanitary requirements were complied with. We are informed, on good authority, that no two school-ships in the kingdom are alike, even in their general internal arrangements, and in fitting out no common principles are adopted. This is a subject well worthy the attention of port sanitary authorities and their officers.

ARROW-WOUNDS AND COMMODORE GOODENOUGH'S DEATH.

THE sad news of Commodore Goodenough's death from wounds received by him on the 12th August last at Carlisle Bay, Santa Cruz, has given rise to a very general feeling of regret. The commodore had landed for the express purpose of conciliating the natives, and of entering into friendly intercourse with them, when the attack, which was entirely unprovoked by anything which his party had done, was made. An occurrence of this kind naturally awakens a feeling of indignation at the treacherous conduct of the natives; but it is much to be feared that in this case, as in that of Bishop Patterson—who, it will be remembered, lost his life under precisely similar circumstances in the Santa Cruz group of islands,—the innocent have been victims to feelings of revenge which the cruel and treacherous practices of others, such as slavers, have aroused in the minds of the natives. Be this as it may, the official list of wounded comprises seven names in all, and of that number no less than three died. The wounds were inflicted by arrows, which are said to have been poisoned, and the same cause of death is assigned in all the fatal cases—namely, tetanus. From the brief description given of the wounds it would not appear that any of them were of a severe character, and with the exception of one, which was but a scratch of the left shoulder, accidentally received, those cases reported as doing well seem to have been as serious as those which proved fatal. We are, therefore, inclined to attribute the fatal issue entirely to the supervention of tetanus—a very fatal disease, especially when, as ordinarily happens, it is of traumatic origin. It is very probable that some climatic peculiarities, together with the nature of the wounds, may have been predisposing causes of this complaint, with the production of which it is extremely improbable that poison had anything to do. Time out of mind poisoned arrows have however, been mentioned and dreaded as weapons of warfare, and woorari is one of the agents employed for the purpose The arrows used by the North American Indians are commonly reported to be poisoned, and it is said that these Indians dip their arrow-heads in rattlesnake poison; but repeated experiments have been made of inserting the points of the arrow-heads beneath the skin of small animals without injury to them. Baron Percy was wont to declare that military surgery had its origin in the treatment of wounds inflicted by darts and arrows. The Surgeon-General's Third Report of the Surgical Cases of the United States' Army contains the most recent account of this description of wounds. In the record of eighty-three cases of arrow-wounds in the Surgeon-General's Report, twenty-six, including nearly all in which the great cavities of the body, or the larger bones or joints, were involved, proved fatal. Dr. Bill, in an interesting essay on Arrow-wounds, remarking on the rapidity with which the American Indians discharge their arrows, states that it is exceptional to meet with a single wound; that if one arrow takes effect it is immediately followed by two or more others.

THE DUTIES OF HEALTH OFFICERS FROM A SCIENTIFIC POINT OF VIEW.

THE Society of Medical Officers of Health auspiciously inaugurated the session of 1875–6 on Saturday evening last, when a considerable number of health officers, including a fair proportion holding appointments in distant parts of the country, assembled to hear an introductory address delivered by the new President of the Society, Dr. Buchanan, of the Local Government Board. The subject of the address was "Some directions of scientific work by medical officers of health." After describing the special opportunities which are open to the medical officers of both large communities and of small rural districts for adding to the information we possess with reference to the nature and causation of disease in general, the President addressed himself especially to impress the importance of scientific inquiry as to the means by which so-called zymotic diseases originate and spread. Above all, he urged the utmost necessity for caution before pronouncing that cases of this class of disease—typhoid fever for example,—however remote and shut off from infection they may appear to be, have a *de novo* origin. Phenomena relating to scarlet fever, its origin and fatality, were also pointed out as awaiting a solution that can only be arrived at by careful investigation extending over a wider field of study than falls to the lot of ordinary medical practitioners. Dr. Buchanan, moreover, pointed out the incompatibility of these important and necessary investigations with the cares and anxieties of medical practice, and thus implied that medical officers of health should form a distinct and specially trained branch of the profession, who, by devotion to the scientific aspect of their duties, would enlist the practising profession as fellow-workers, to the great advantage of science. Such a result would afford some consolation for the frequent inability of medical officers of health to enlighten vestrymen and boards of guardians, and to arouse in them a due appreciation of their sanitary responsibilities. A considerable portion of the address was devoted to the consideration of epidemic diarrhœa, which a study of the old Bills of Mortality has induced Dr. Buchanan to think may possibly be of comparatively modern origin. It was pointed out how little is at present known as to its exact causation, and the reasons for its variable degree of fatality in different town populations, apparently of very similar constitution. Information which might reasonably be expected to result from the various lines of observation and inquiry suggested by Dr. Buchanan, could not fail to be valuable alike to pathologists and to health officers. The failure of a limited inquiry into the causes of the excessive mortality from diarrhœa in Leicester a year or two since to yield satisfactory conclusions should not deter other inquirers in the same field. These, and similar investigations, come especially within the province and opportunities of officers of health, and Dr. Buchanan urged that the analysis and accumulation of the results of such investigations, for the use of other workers, were among the chief functions of the Society of Medical Officers of Health.

Dr. Buchanan's conception of the duties and opportunities for useful work of medical officers of health, as worked out in his excellent address, which we have thus briefly noticed, stands out in pleasing contrast to the idea which too long prevailed at the Local Government Board that the medical officer of health was little more than a head inspector of nuisances, who, by a blunder of the Public Health Act of 1872, was obliged to be a medical man. It is clear that a large majority of health officers have been appointed under a very different conception of their duties from that formed by Dr. Buchanan, but it is easier to see the blunders that have been made than to secure their being corrected. We trust that the publication of Dr. Buchanan's address will render it accessible to all medical officers of health, as well as to the profession generally.

SANITATION IN THE CITY OF LONDON.

DR. SEDGWICK SAUNDERS, medical officer of health for the City of London, has reported 478 houses, comprising 2116 rooms—in which 4315 persons reside,—covering 380,369 square feet, or nearly eight acres and three-quarters, distributed over the City, as "unfit for habitation if a high standard of health is to be maintained." This looks like business, and will be hailed with satisfaction by sanitary reformers. Some isolated parishes in the metropolis, Birmingham, and the City of London, have now the honour of leading the crusade against the conditions inducing disease and decrepitude. We trust it will be remembered by corporations and local sanitary authorities of all classes that when once a medical officer has made his official "representation" the case is out of his hands; he has done his duty. It would be illegal for him to amend his report so as to meet the wishes or the convenience of his employers. The onus of declining or determining to carry out such repairs as the "representation" may declare necessary rests entirely upon the sanitary authority, and, whatever decision they may arrive at, the communication of the medical officer's report to the confirming authority (in London the Home Secretary) is a proceeding which cannot be evaded. If medical officers bear in mind where the appeal now lies they will not hesitate to discharge their public duty.

INFANT MORTALITY IN MANUFACTURING DISTRICTS.

INFANT LIFE is especially sensitive of sanitary condition hence all urban populations show a large excess of infant mortality compared with that which prevails in rural populations. This excess is proportionally largest in manufacturing urban populations. In the year 1874 infant mortality, measured by the proportion of deaths under one year to births registered, averaged 124 per 1000 in the rural population of Wiltshire, Dorsetshire, Devonshire, Cornwall, and Somersetshire; whereas it was 172 per 1000 in the West Riding of Yorkshire, and 181 in Lancashire. In other words, 3768 infants under one year of age died during the year in the West Riding, and 6885 in Lancashire, who would have survived if the rate of mortality had not exceeded that which prevailed in the rural counties before mentioned. Infant mortality in the eighteen largest English towns, measured as above, ranged in 1874 from 151 and 153 per 1000 in Portsmouth and Bristol, to 200, 215, and 233 respectively in Leeds, Leicester, and Liverpool; it was equal to 189 in Bradford, and 195 in Nottingham. Leicester and Nottingham are examples of towns in which the death-rates at all ages in 1874 were below the average rate in the eighteen towns, but in which the rate of mortality among infants under one year of age showed a marked excess. This fact is suggestive when taken in connexion with the large proportion of women engaged in manufactures in those towns.

This marked excess of infant mortality in manufacturing populations, although often commented upon, has scarcely yet received the attention from medical officers of health which it deserves; and it is only by local investigation that the influence of female labour in factories upon infant mortality can be correctly determined. In the meantime, however, much may doubtless be done in manufacturing towns to control and reduce this infant mortality, by providing institutions where infants may be properly tended while their mothers are employed in mills and factories, instead of being put out to nurse with old women, or left in charge of children little more than infants themselves. We are glad to notice that a Children's Day Nursery has recently been opened in Bradford under very favourable auspices, for the reception of infants aged between one month and five years. The institution is not intended to partake of a charitable character, as the fees that are to be charged for the care of the infants will, it is hoped, make it self-supporting. The whole is under the care of a competent matron, who will be responsible for the judicious feeding of the infants with wholesome food. The ladies and the employers of labour in Bradford will do well to impress upon the workpeople the advantages of this institution, which, if freely used by those for whose benefit it has been started, will doubtless soon tend to reduce the present high rate of infant mortality in this busy manufacturing town.

THE RELATION OF THE DISCHARGE OF OVA TO THE PERIOD OF MENSTRUATION.

THE interesting question of the relation of the discharge of ova to the period of menstruation has recently been the subject of a paper by Dr. John Williams, of University College Hospital, which has been read before the Royal Society. It was not till a comparatively recent period that the connexion between menstruation and the discharge of ova was ascertained, and we owe to M. Coste the determination of the fact, that though the rupture of a Graafian follicle is usually synchronous with the epoch of menstruation, the coincidence in point of time between the two is not absolute; for cases are on record where menstruation has occurred, yet in which the minutest investigation has failed to discover the presence of a ruptured sac. Nevertheless, in the great majority of cases there can be no doubt that the escape of an ovum from the ovary and the discharge of blood from the uterus are associated events. The point that Dr. Williams has endeavoured to determine is, at what period in the course of the month the separation of the ovum takes place. He has had the opportunity of examining a series of cases, in all of which the period of menstruation was known. In some of these a Graafian follicle had been matured and had actually ruptured. In others, a Graafian follicle had been matured, and hæmorrhage had taken place into the cavity, but no actual rupture had occurred. In one case a Graafian follicle had matured, but neither rupture nor hæmorrhage had actually occurred; and, lastly, in three cases no Graafian follicle had become enlarged to the size exhibited by it at maturity. From his observations, Dr. Williams has come to the conclusion that, in the great majority of cases, the discharge of ova takes place *before* the appearance of the menstrual flow with which it is connected; for in ten out of fourteen cases rupture of a follicle or hæmorrhage into its cavity had occurred before the return of the catamenia; in one it was doubtful whether rupture of a follicle or the appearance of the discharge would have taken place first; in two a menstrual period had passed without the maturation of a follicle; and in one a periodical discharge was imminent, though the ovaries contained no matured Graafian follicle. It is not improbable, he thinks, that the follicles which were found in the last three cases, and which were enlarged to the size of a small pea, would have become mature by the next return of the flow. An interesting point was long ago made out by Coste, that in rabbits the excitement of the act of intercourse, and even of the desire to copulate, makes a difference in the period at which the Graafian follicles rupture, since when two sets of these animals were examined, one of which had been allowed access to the male and were taken away before connexion, whilst others were not allowed to see the male, the follicles, when the animals were killed, ten or twelve hours after, were ruptured in the former and unruptured in the latter.

RESEARCHES ON THE OVARY OF THE FŒTUS AND NEW-BORN CHILD.

Two sets of investigations on this subject have just been published, one by Dr. Haussmann in the *Centralblatt* (No. 32), and one by Dr. Sinétz in Brown-Séquard's *Archives de Physiologie* (No. 5). It has long been known, in fact it was observed by Malpighi and Vallisneri, that the Graafian follicles are occasionally found fully developed in the fœtus at about the full period, and Grohe and Slawjansky, as well as Haussmann, have satisfactorily shown that the constricting off of the primordial follicles and the growth of the Graafian follicles, though not their rupture, is quite independent of the menstrual period. Haussmann's observations, which were made upon eighty-four subjects, show that such premature development of the follicles takes place in about 10 per cent. of all cases, and he alludes to it as a possible and hitherto unsuspected cause of amenorrhœa and sterility. Dr. Sinétz goes so far as to maintain that at about the period of birth a sudden development (*poussée*) of the internal organs of generation always takes place in connexion with the development of the mammæ that occurs at the same period. The hypertrophy of the Graafian follicles observed at this age must not, however, he thinks, be regarded as the point of departure of ovarian tumours, but of a normal, more or less active, physiological process.

VENTILATION OF SHIPS.

This subject appears to have attracted some special attention lately, as evinced by communications that have appeared in the *Shipping Gazette* and elsewhere. Until, however, in this, as in other matters afloat, the Admiralty set some sort of example by building ships on sanitary as well as offensive and defensive principles, very little good will be effected in the mercantile marine. With some few exceptions, no trouble whatever is taken, when her lines are laid, to render a ship habitable. Cowls and so called up-casts and down-casts are put in here and there in a haphazard way after the vessel is built, no principle at all being evident in the process. It is now generally admitted by those who have studied the matter that efficient ventilation afloat, particularly of the nethermost parts of the ship, as the skins, bilges, and holds, is best promoted by adhering to the "exhaust" system in its entirety, leaving the fresh air to find its way in as best it may. This was well shown in detail in a lecture delivered last year at the United Service Institution by Admiral Ryder (an abstract of which appeared in The Lancet at the time). The exhaust principle can be applied equally well to ironclads and monitors as to ordinary steam- and sailing-ships. In other vessels the curved syphon exhaust-pipe makes a good up-cast if properly attended to. In all vessels the skins and the bilges should be ventilated either by syphoned goose-necked tubes with outlets just above the bulwarks, or, as we think, better still, by the "patent self-acting ship ventilator," which has been fully described in The Lancet, and can be arranged so as to eject foul air and also bilge-water. It must be remarked, however, that this latter plan does not work in ships at fixed moorings, and so is not applicable to school-ships or training-ships. All communication between the framing of the ship and the inhabited decks should be cut off. In large passenger-ships it will be found that if plenty of properly arranged up-cast ventilation be provided, fresh air will readily find its way down the hatchways, companion-ladders, skylights, &c. In the best-arranged school-ships, however, the reverse obtains, for the fresh air is brought in through the ports or scuttles and conveyed to the floor of the decks by large tubes, the hatchways then serving as up-casts, so that under such circumstances the lowest deck is usually most free from impurities. In small vessels trading in the tropics lower forecastles ought to be abolished altogether, and deckhouses erected between the fore and main masts. Much of the sickness and mortality off the West Coast of Africa arises from the disgraceful way in which the crews of these small vessels (that trade between this country and Lagos) are lodged.

These are merely fragmentary jottings on a very large and important matter, which ought to be dealt with as a whole. But ventilation afloat cannot be effective until the naval architect, in considering form, speed, strength, durability, and appearance, considers also how health and comfort can be best maintained in the ship that he is about to design.

THE CHOLERA IN INDIA.

The reports from India show that cholera has been prevailing of late in that country to an extent calculated to give rise to some apprehension. The disease has not, however, extended itself regularly, rapidly, or widely, after the manner of progression of one of those great epidemics which have been the scourge of India; but it has still been very widely distributed, outbreaks of cholera or sporadic cases of that disease having occurred at a great number of stations and places in the different presidencies. It would be nearly impossible to enumerate the names of all the places at which it has appeared. Judging from the reports, we should say, speaking generally, that the disease has of late greatly subsided, and that it is still subsiding. In the North-Western Provinces, though still lingering in certain districts, it is uniformly on the decrease; and the districts chiefly affected in the Punjab have been Delhi, Umballa, Jullunder, Rohtur, and Simla. As regards the last-named place, we learn that the disease appears to have begun soon after the middle of June, and to have been mainly confined to the natives, although not by any means exclusively so, for several deaths from cholera occurred among the European residents and visitors of all classes. Whether it were a case of importation, as some think, from the people along the foot of the hills, where cholera was very prevalent, we cannot say; but one thing is certain—viz., that nothing could be worse, from a sanitarian's point of view, than the condition of Simla bazaar; and the state of the water-supply has also been frequently adversely reported on. The disease has not, however, exclusively attacked those residing in the most insanitary places; on the contrary, it is said to have prevailed relatively quite as much, if not more, among those more favourably circumstanced in this respect. Dr. Cunningham, the sanitary commissioner, without attempting to unravel this knot, thinks to cut it by his proposed total abandonment of Simla for three years at least. As the *Pall Mall Gazette* remarks, the Prince of Wales's visit to India is fortunately so timed that there is no prospect of his being tempted to visit Simla. Cholera has also prevailed in many parts of the Madras Presidency, chiefly among the native population, at Madras, Trichinopoly, Bellary, and Mysore; and Bangalore has not escaped. The cholera season, as it is termed, will however soon be over in India, and already, as we have said, there is every indication, by the decreasing number of cases, of its disappearance before the arrival of the Prince of Wales in that country.

SANATORIA FOR INFECTIOUS CONVALESCENTS.

A WRITER in *The Times* of Wednesday suggests that sanatoria for the upper classes should be established at seaside places; we presume he means for all classes that can afford to use them. It is amazing that such establishments have not been realised ere this. But they have become an urgent necessity. We shall also need special trains or carriages for the conveyance of the sick. The reckless way in which infectious convalescents travel about would be incredible apart from experience. Sometimes it is done furtively and in pure selfishness, sometimes in ignorance. Two illustrations have come to our knowledge within the last few days. A respectable woman at Folkestone, who lets apartments, always makes it a point of conscience to ask applicants for her rooms if they have had any infectious disease. On putting this question to a lady lately, the lady was mightily offended, and said she regarded the question as a piece of impertinence. She promised to call again in the afternoon, but did not. The reason may be surmised. Probably she found a landlady less conscientiously inquisitive. A still worse case occurred lately at Margate. The owner of certain rooms there let them to a family. She found after admitting them that they had had scarlet fever a month before. Her own children, three in number, took the disease, and have had prolonged and nearly fatal illnesses. Nothing more gratifying has lately occurred than the fining of a gentleman for conveying his son in a cab to the Fever Hospital. But this is no remedy for such a calamity as that which is conveyed to healthy people by infectious convalescents. These cases show the need both for a sanatorium and for a law to punish more effectively the disastrous selfishness of those who propagate disease, believing that they can do it without being detected.

COOKING FOR THE SICK.

WE have heard a great deal of late about the need of better cooking for the poor. It has been shown that improved results, as regards the quality of food, can be obtained with greater economy by new processes. The value of these suggestions cannot be exaggerated. Meanwhile the needs of the sick and convalescent ought not to be overlooked; they are urgent and special. Nothing so much conduces to the successful treatment of patients in all stages of a malady as good nursing, and cooking plays a prominent part in the *régime*. Notwithstanding this circumstance, which must be universally recognised, it is the exception to find a cook who can serve up a basin of gruel or arrowroot, a cup of beef-tea or broth, or any simple beverage suited to the sick chamber, in a fashion likely to tempt the failing, whimsical appetite, and humour the digestive powers of an invalid. So apparently simple a culinary process as beating up a new-laid egg in a cup of warm milk or tea without curdling it, is a feat which can rarely be accomplished. Every practitioner who has looked into these matters carefully must have felt the need of a system of special cookery for the sick. If someone would devote sufficient attention to the subject to produce a clear, explicit, and yet concise manual of cookery for invalids, with intelligible recipes and directions, the gain to patients and medical practitioners would be considerable, and the appearance of such a brochure would be hailed with pleasure and attended with success. Attempts have from time to time been made to supply the need, but they have failed from being treated as complementary to some general effort to improve the art of cookery, or adapted only to a class of society in which every want can be supplied without stint or trouble. The object to be obtained is more simple and yet not less difficult. It is to show persons of ordinary intelligence and with limited means how to compound and serve up the common necessaries of the sick diet with cleanliness, taste, and delicacy. For such a boon everybody concerned would be exceedingly thankful.

GLANDERS.

THE minute anatomy of the morbid changes in glanders has been carefully examined by M. J. Renaut, and his observations have been communicated to the Académie des Sciences. He has found that the pulmonary "tubercles" in the horse are composed of a number of granulations, commonly united in a racemose arrangement, and often grouped around a small bronchus. These recent granulations, composed of embryonal cells, usually fill each a pulmonary alveolus, and differ very little from those found in pyæmia in man. The neighbouring alveoli of the lung are filled with blood—in some undergoing retrogressive changes, and in others more recently extravasated. In the older granulations the centre had undergone fatty degeneration, and the cellular elements had become transformed into true pus, which ordinarily undergoes a caseous change. The cheesy nodule subsequently becomes softened, or undergoes slow atrophy. Meanwhile the lung becomes the seat of chronic inflammatory processes, points of sclerosis are found around the smaller bronchial tubes and in the tissue of the lung around the cheesy nodules. These changes, it will be seen, are by no means peculiar to glanders. The granulations of the mucous surfaces are closely analogous to those of the lung. The central growth is surrounded by an area of chronic inflammatory change in the mucous membrane, the lesion ultimately becoming stationary or undergoing caseation. The arterioles also become inflamed; their diameter is lessened, they cease to be permeable to blood, and ulceration is the common result of their obstruction. The author points out the curious analogies of this condition with many forms of blood-poisoning, which all have the common origin in septic material derived from without.

THE EPIDEMIC OF FEVER IN CROYDON.

THE Registrar-General, in his return for the week ending 16th inst., calls attention to the continued prevalence of fever at Croydon, and notes the fact that 62 deaths have there occurred since the outbreak of the epidemic towards the end of February last. Whether the epidemic may have been due to the intermittent water-supply, or to the sewage farming, or to the combined effects of both, or to some entirely distinct and at present unsuspected cause, the long-continued prevalence of the disease and its recently increased fatality invest it with more than local importance. It may be useful to notice, chronologically, the fatal results of the outbreak. One death was referred to fever in the sub-district of Croydon during the week ending 16th January, but the next fatal case was not registered until the week ending 27th February. In the following six weeks the deaths averaged one per week, while in the next nine weeks, ending June 12th, they increased to rather more than 3 per week. During the next twelve weeks only 14 fatal cases were recorded, whereas in the following six weeks ending 16th inst., they were again more numerous, and averaged rather more than 2 per week. It should be stated that these numbers are derived from the Registrar-General's weekly table of deaths in the "Outer Ring" of London, and that they all relate to the sub-district of Croydon, which includes a considerable population in addition to that of the parish and Local Board District of Croydon. It is probable, however, that nearly all the deaths from fever occurred within the parish of Croydon.

HYPODERMIC HYDRIC INJECTIONS.

IT is generally considered that subcutaneous injections of alkaloidal solutions are of great value. M. Lafitte, however, at the Congress of Nantes, attempts to demolish the whole thing, and contends that, not the alkaloid, but simply the water, distilled or not, has the merit of allaying pain. Startling cases are mentioned (*l'Union Méd.*, Nos. 113 and 114, 1875), and from these we find that severe lumbago, obstinate neuralgia, &c., are instantly relieved by the injection of about thirty drops of water. Failures are but few, and the author consoles himself respecting these by the consciousness of not having done any harm if he did no good. And here, as a matter of course, follows a rather exaggerated picture of the evil consequences of the different alkaloidal injections.

M. Lafitte now asks himself how the simple water acts, and he throws out the theory that the ultimate nerve filaments are compressed by the water, and, being thus paralysed, can no longer convey the sensation of pain. Be this as it may, M. Lafitte goes the whole length of maintaining that all the hypodermic injections hitherto performed acted through the agency of the water, and he is very particular in stating that his operations were never followed by abscesses or any unpleasant symptoms. We have failed to ascertain, however, whether these aqueous injections, besides relieving pain, may induce sleep.

As a set-off we have, on the other side, M. Pillet (*l'Union Méd.*, No. 116, 1875), questioning the soundness of M. Lafitte's doctrine, and stating that both in public and private practice he met with signal failures in following it. He, however, asks which are the cases best suited for the hydric injections, and the proper steps of the operation. The question will, of course, immediately arise whether the patient's mind is not an important factor in the results obtained. But M. Lafitte has taken care to operate almost unknown to the patient; he has injected without apprising the latter of his purpose, and pain was always instantly relieved. These affirmations are worthy the attention of our hospital surgeons.

THE LOCAL GOVERNMENT BOARD AND COMPULSORY VACCINATION.

THE board of guardians of the Stockport Union have appealed to the Local Government Board for advice as to how the guardians should deal with six persons who had already been convicted under the Vaccination Acts. The drift of the reply of the Local Government Board is that the guardians must use their discretion in each case. A repetition of legal proceedings has in numerous instances had the effect of procuring vaccination when a first prosecution has not succeeded. On the other hand, the Board admits that in some cases the continuance of a fruitless contest might have a tendency to produce mischievous results, by exciting sympathy with the person prosecuted, and thus creating more extended opposition to the law. The Board's advice is good. No abstract rules will do away with the need for discretion on the part of the guardians. One prosecution is altogether right and healthy; it educates public opinion and does not irritate. But even stupid people are apt to excite sympathy when twice fined for an offence which they have not brains to understand.

EFFECT OF ACID VAPOURS ON HEALTH.

DR. ANGUS SMITH, in his eleventh annual report of proceedings under the Alkali Acts, just issued, gives some interesting information on the influence of acid vapours on health. Among other observations, the inspector says it may be taken for granted that where trees flourish there also man is uninjured by acids such as are given out by chemical works, the effect on vegetation being more striking than upon human beings. The general conclusion is that gases from chemical works are hurtful to the health; nor can they, on the other hand, be said to be curative in certain diseases, as so many suppose. In collating the statistics of a district peculiarly exposed to the fumes from alkali works, Dr. Smith was struck with the following points:—1. That bronchitis was not high. 2. That scarlet fever, which gases might be supposed to disinfect, was very high; whilst whooping-cough, often thought to be benefited by the fumes, was low.

MEDICAL PSYCHOLOGY AND THE EDINBURGH CURRICULUM.

THE University of Edinburgh has lately made an important change in its curriculum for the degree of M.D. Previously to last year the candidates for that degree must have passed an examination in Arts on certain subjects, of which Moral Philosophy was one; but in the course of last winter it was decided to allow Bachelors of Medicine, going up for the higher degree, to profess in Medical Psychology as an alternative subject for Moral Philosophy. The change came into operation on the 13th inst. We understand also that provision will be made for encouraging the practical study of mental diseases by candidates for the degrees of Bachelor of Medicine and Master of Surgery, by allowing three weeks' clinical clerkship at a public hospital or asylum for the insane to be taken alternatively for the same period of out-door hospital or dispensary practice. By this means a more thoroughly practical knowledge of insanity will be got than by mere attendance at the visits of the superintendent.

SUDDEN DEATH AFTER THORACENTESIS.

M. LEGROUX, deputy professor at the Faculty, brought before the Medical Society of the Paris hospitals the following case at the meeting of July 23rd, 1875:—The patient was a prisoner, aged fifty-two, and being admitted into the infirmary was found to be suffering from effusion in almost the whole of the left side of the chest, in consequence of pleurisy. The latter complaint had been caused by a severe fall on the ribs. The dyspnœa was so distressing that M. Legroux decided on thoracentesis, and plunged the trocar, in the axillary line, into the seventh intercostal space. As much as two quarts of yellowish-pink serum was obtained. The patient had then a little cough, and expressed himself much relieved. The operator, thinking that all was now right, left the hospital; but three-quarters of an hour afterwards the patient exclaimed suddenly, "I feel faint"; his head fell on the pillow, and he expired. The autopsy did not reveal any tangible cause of this sudden and fatal issue.

ENTERIC FEVER IN PARIS.

The weekly report on the sanitary condition of Paris, relating to the seven days ending the 15th inst., showed a marked increase in the fatal cases of enteric fever, which were returned as 52, against 19 and 12 in the two preceding weeks. The deaths in London referred to this disease in the same week were but 22. They would have been 97 had enteric fever been as fatal in London as in Paris.

In the annual report of Mr. Dyke, medical officer of health for Merthyr Tydvil, to which we have already briefly alluded, will be found some opportune testimony in favour of the innocuousness of sewage farms, and which may be influential in removing some of the violent objections raised against this method of disposing of sewage in many parts of the country. Mr. Dyke describes how cleanly, odourless, and perfect in all its details is the action of the system. He has frequently examined the water "flowing out," and satisfied himself that there has been no perceptible increase in the amount of organic matter dissolved therein. The growth of vegetables on the surface and the drainage, do the work of purification effectually. Lastly, Mr. Dyke says that at Merthyr there are hundreds of young children brought up on the milk of cows fed partially on grass grown on sewage-irrigated meadows, who exhibit exceptionally good health.

It is, perhaps, not generally known that the London Fever Hospital, while receiving patients of a certain class free of charge, is yet able to afford separate accommodation for those in a position to pay for their treatment and keep. The Board of Management wish it to be known that their private wards are always open for the reception of paying patients, who may be visited at any time by their customary medical attendants; and that domestic servants or persons employed in shops are received on a payment of two guineas for the entire illness. Poor working people brought from their own homes are admitted free, and if required the hospital ambulance will be sent for them conditionally on reimbursing the hospital authorities for the sum actually paid for the hire of a horse. Heads of families and others should be made aware of the great facilities offered by this institution for the reception and treatment of cases of infectious disease.

Dr. Thorne Thorne, medical inspector of the Local Government Board, who some time ago visited Cleveland in order to report on the continued prevalence of fever in the district, has recently issued a statement in which the results of his inquiries are embodied. It is shown that the epidemic was due in a great measure to easily preventable causes. The condition of some of the villages inhabited by miners was filthy in the extreme. There is little doubt that a moderately vigorous sanitary administration would soon reduce the death-rate from zymotic disease in the district. Dr. Thorne's report has been forwarded to the local authorities, and will, it is to be hoped, receive earnest consideration.

The Local Government Board have authorised the appointment of a medical officer of health for the Atcham Bridgnorth, Church Stretton, Cleobury Mortimer, Clem Forden, Ludlow Madeley, Newport Shiffnell, and Tenbury rural districts, and the Much Wenlock and Tenbury Wells urban sanitary districts. The future salary is reported to be £800 per annum.

Dr. James Adams, medical officer of health, in reporting on the sanitary condition of the Richmond Rural District, gives a favourable account of all portions of the district save Mortlake. In the latter place diseases of the zymotic character have been very prevalent, in especial a serious outbreak of diphtheria caused much trouble and anxiety. It was found, on examining the houses where this disease showed itself, that the sinks, waterclosets, &c., had direct communication with the sewers; there was no provision for ventilating the drains. The whole of the sewers were in an extremely foul condition, unventilated and unflushed, and charged with noxious gases which could find vent only into the dwelling-houses. Means for rectifying these gross defects have been generally adopted, but there is clearly yet a great deal to be done in Mortlake if it hopes to diminish its mortality from preventable diseases.

The Indian correspondent of *The Times* states that a new Opium Bill has been introduced into the Legislative Council by Sir William Muir, and is now before a select committee. Its object is "to assimilate the laws relating to the growth and manufacture of the drug in Bombay and Madras to those in force in the Bengal Presidency." In Madras there is no check whatever on the growth of opium, while in Bombay it is practically the same. We may here state that in Bengal no one is permitted to cultivate opium who will not undertake to deliver the entire crop to Government agents at the contract price. The opium is, after preparation, sent to Calcutta, where it is sold by auction, in which Chinese agents buy largely. The drug contributes more than six millions of the gross annual revenue of Bengal.

The Local Government Board, in replying lately to a communication on the subject of the payment of Poor-law medical officers for the supply of returns of sickness, states "that it is competent for the sanitary authorities, if they think proper to do so, to enter into an arrangement to pay district medical officers reasonable remuneration for supplying the medical officer of health with information which he requires for the efficient discharge of his duties." After this sanction to pay parochial surgeons, local authorities will now have no excuse for pressing a laborious class of public servants to perform gratuitous work, and it would only be right for these gentlemen generally to insist on "reasonable remuneration."

In London last week 1442 deaths were registered, including 1 from small-pox, 23 from measles, 122 from scarlet fever, 9 from diphtheria, 37 from whooping-cough, 29 from different forms of fever, and 78 from diarrhœa. Different forms of violence caused 44 deaths. The fever and small-pox hospitals contained last Saturday 320 patients, of whom 250 were under treatment for scarlet fever, and 1 only for small-pox. In the outlying suburbs cases of enteric fever continue to be reported.

The managers of the Haverstock-hill Provident Dispensary, being dissatisfied with the award of the Hospital Sunday Committee last year (£12 15*s*. 6*d*.), thought themselves justified in asking the local clergy for special grants from their Hospital Sunday collection. These amounted to £70. The Dispensary is well worthy of a better grant than was awarded by the Hospital Sunday Fund. The institution has now 4000 members on its books.

Official reports have been made by the Medical Inspector of the Board of Trade during the past week as to two more vessels that have returned to England with cases of scurvy on board.

IN an article on the Recognition of Sanitary Medicine, which we published last week, we attached some blame to the Royal College of Physicians of London for its want of interest in this important subject. Whilst still adhering to the general charge of remissness, we are reminded that Dr. Acland, in 1871, delivered a lecture before the College on Sanitary Medicine and the Mode of Dealing with Preventable Diseases.

WE regret to have to announce the death, at the early age of forty, of Dr. W. J. Hunt, who for some years filled the position of resident physician and superintendent of the Hoxton House Asylum. He was also assistant-physician to the Metropolitan Free Hospital, and latterly had lectured on mental diseases at the Charing-cross Hospital.

DR. AQUILLA SMITH has again been reappointed to represent the King and Queen's College of Physicians in Ireland on the General Medical Council, this being his eighteenth anniversary. Dr. Smith is also an active member of the Executive Committee of the Medical Council.

THE Metropolitan Board of Works has instructed its chemist, Mr. Keates, to analyse samples of mud taken from the bed of the Thames near the main-drainage outfall. We shall be curious to learn the result of the examination, which cannot fail to be interesting.

UNDER the Apothecaries' Act the East London British Medical Defence Association have recovered two penalties of £20 each from persons who were illegally practising in the East-end of London.

SMALL-POX.

THE recent epidemic of small-pox in the United Kingdom, in its relation to vaccination and the vaccination laws, forms the subject of an important paper compiled by Dr. Seaton, and which forms part of the Appendix to the fourth of the new series of Reports recently submitted by Mr. Simon to the Local Government Board.

The epidemic, which commenced in England towards the close of 1870, and terminated about the middle of 1873, was part of a general outbreak of the disease, as Dr. Seaton remarks, "of world-wide diffusion, marked wherever it occurred by an intensity and malignancy unequalled by any previous epidemic of the disease within living memory." It appears to have commenced in France towards the end of 1869, but, except that in some cases it was conveyed direct by the French prisoners, no extension into Germany or elsewhere took place until the close of 1870, when it became established in London, in some towns of Holland, in Milan, and Geneva, and soon became rapidly diffused throughout. In 1871 the full force of the epidemic was felt; the disease commenced also in Denmark and Iceland, and spread to various places in Africa (where it raged along the Gold Coast), to the West Indies, and to North America. The inhabitants of St. Petersburg and Vienna were extensively victimised in 1872, but about the middle of 1873 the spread of the disease may be said to have terminated, and since then small-pox has been quiescent, with the exception of some few considerable local outbreaks.

The information gleaned by the writer showed that the peculiar intensity of this epidemic was manifested by the great diffusiveness of the disease, by its attacking an unusual proportion of those who were regarded as protected against the disease either by previous small-pox or vaccination, and by the occurrence of frequent cases of a malignant or hæmorrhagic type. The actual mortality, however, varied very considerably, being determined in different countries by the state of their respective populations in regard to vaccination.

The occurrence of this epidemic had been anticipated by previous observation and experience, and the gradual rise of mortality during 1870 (most marked in London) induced the authorities of the Privy Council, with whom then rested the supervision of public vaccination, to give official warning to certain metropolitan boards of guardians who had been negligent in the administration of the Vaccination Act of 1867. The intensity of the outbreak was manifested in an extraordinary degree, the ordinary mortality of natural small-pox increasing from 35 to 47 per cent. on all cases admitted into the Highgate Hospital, and the post-vaccinal cases from 7 to 10 per cent. London and Liverpool first felt the force of the epidemic. They contributed together 879 to the 1229 deaths that occurred in the last quarter of 1870, and the apparent decline of the epidemic in England in the third quarter of 1871, with its apparent subsequent rise, were owing to the fact that the disease had subsided in these two great towns, while it was steadily progressing over the rest of the kingdom. The mining districts in the North of England and parts of South Wales were next affected, and during the entire epidemic the south-eastern and south-midland counties, notwithstanding the proximity to London, suffered least. The mortality in all the mining districts was exceptionally high, influencing in a marked degree the death-rates of the counties in which they are situated.

The epidemic invaded Ireland in the third quarter of 1871, and lasted until the second quarter of 1873. Belfast and Dublin suffered most, but the chief mortality was in Dublin and Cork, at which latter place the death-rate reached to 9·6 per 1000 of population, a higher rate than that of any large town in England.

Scotland was attacked in 1871. The deaths of that year amounted to 1432, or 0·42 per 1000 of the population, but statistics as to the following years are not yet forthcoming. Edinburgh, Leith, Glasgow, Dundee, and Aberdeen contributed chiefly to the mortality, and the epidemic lingered in Glasgow and Greenock until the spring of last year.

The history of the epidemic as it affected the continent of Europe is incomplete and faulty, because in most of the States statistics of the causes of death are either not kept or kept very imperfectly, and also because the abstracts of others are not yet completed. In Prussia, which, after France, was the first continental State to feel the force of the epidemic, had a death-rate for the disease in 1871 equivalent to 2·43 per 1000 of population, or nearly twice and a half the small-pox death-rate in England for the same year. Holland, where the official information on sanitary questions in this case is always very complete, shows a death-rate in 1871 of 4·3 per 1000 of population. Sweden was little affected by the epidemic, and Denmark in 1871 and 1872 had a small-pox death-rate of only 0·2 per 1000 of population. In the State of Hamburg the epidemic was very severe, and the total small-pox deaths in 1871 amounted to 3647, or 10·76 per 1000 of population. No official account of Saxony are forthcoming except that of Leipsic, where the death-rate amounts to 10 per 1000; and no general records of death cases exist either for France or Belgium. In Austria the small-pox death-rate in 1871 was 0·36 per 1000, and in 1872 1·8 per 1000 of population; but it was very fatal in 1873, the returns for which are not yet forwarded. No accounts are given as to Italy, Spain, or Portugal, nor as to Russia except St. Petersburg, in which city 1850 deaths were reported between April, 1872, and June of the following year. The above *résumé* shows that, with the single exception of Denmark, no country has exhibited so low a rate of mortality as the United Kingdom. The death-rate of Prussia was considerably more than twice and that of Holland three times as great as that of England, and the difference is still greater on comparison with Ireland.

An analysis of the mortality of the epidemic in England at different ages shows that of the 42,220 small-pox deaths which took place in England in 1871 and 1872, 5817 were in children under the age of one year. This, of course, brings us to the consideration of small-pox in its relation to vaccination and the vaccination laws, and this must be reserved for a future notice.

Correspondence.

"Audi alteram partem."

"A STANDARD SPHYGMOGRAPHIC TRACING."

To the Editor of THE LANCET.

SIR,—It appears to me more than probable that some member of the profession far more competent than myself to give an opinion upon the subject will take notice of the letter with the above title, which appeared in your journal of October 16th; but if I am mistaken, I shall feel obliged by your allowing me a small space for the following remarks.

We have recently been told a great deal about the physical condition of Captain Webb, and now Dr. Fancourt Barnes has kindly given us a pulse tracing, for which I at least am much obliged to him, as I was anxious to know what was the state of heart of the man who has performed one of the most marvellous feats on record, and one which perhaps no medical man had deemed possible.

But I would ask Dr. Barnes upon what grounds does he expect physiologists and other students of the sphgymograph to accept this tracing as the type of a healthy vigorous heart? Is it from his own personal experience, or is he guided alone in his opinion by the history and powerful frame of the individual in question?

If the former, I can only say his experience is quite contrary to that of all men (so far as I am aware) who have recorded their observations, and who accept the perpendicular up-stroke and the immediate gradually sloping downstroke (with an almost imperceptible convexity at one point to indicate the secondary wave) as the normal radial pulse-tracing.

I quite agree with Dr. Barnes that, in connexion with Captain Webb's recent feat of strength and endurance, it is especially interesting to put this tracing on record, for there are some very characteristic observations to be made concerning it, provided that immediately prior to the application of the sphygmograph Captain Webb had done nothing to excite the heart to more than normal action.

The first point to which I would draw attention is the numerical force of this pulse, of which no mention has been made by Dr. Barnes, but it is at once observable how very close to one another are the individual pulsations, indicating a rate of over 120 per minute, if the instrument used was a "Marey," in which the five-inch slide completes its transit in about ten seconds. The second point to be observed is the slight curve to the left of the up-stroke and the very sudden fall of the down-stroke, indicating an abnormal forcible contraction of the left ventricle. And, lastly, the marked dicrotism or convexity due to the secondary wave, produced by the consequent sharp recoil of the column of blood on the aortic valves.

The tracing is, in fact, typical of a heart that has undergone some inordinate strain and has taken on a condition of irritability, with probably some hypertrophy, which after a certain period of rest would return to its normal state.

It is precisely the character of pulse which I invariably find in those young soldiers whose hearts have been overstrained in their special calling, a subject to which I have devoted some attention,* and it is in this functional derangement of the heart, when the stethoscope can reveal little or no defect, that the sphygmograph may be found, I believe, of great diagnostic value.

No one can doubt that Captain Webb's heart must have undergone a terrible strain, and whilst I think some apology is due to him from me for making the above strictures upon its present condition, as shown by the sphygmograph, I may add that this temporary disturbance of healthy action is by no means surprising to

Your obedient servant,
A. B. R. MYERS,
Surgeon, Coldstream Guards.

Coldstream Guards Hospital, Vincent-square, S.W.,
October 18th, 1875.

P.S.—Let me add that a tracing very similar to that given by Dr. Barnes may generally be obtained by making a healthy man run, or by other sudden excitement of the heart's action, previous to the application of the sphygmograph.

THE EPSOM COLLEGE.

To the Editor of THE LANCET.

SIR,—Now that you are directing your attention to the sanitary condition of public schools, I think it may not be inopportune if I mention to you the fact that there have been several cases of scarlet fever at Epsom College—several mild cases towards the latter end of last term. The boys have only returned to the College about a month, and several cases have occurred already.

I have heard from many Epsom boys great complaints of the badness of the water and the food.

I am, Sir, yours faithfully,
A GOVERNOR OF THE MEDICAL BENEVOLENT COLLEGE.

October 17th, 1875.

IRELAND.

(*From our own Correspondent.*)

THE state of the houses in many parts of Dublin has attracted the attention of all having the public weal at heart. The local daily papers are now occupied with corporate discussion and public comment on the subject. Sanitarians have long since and again invited the notice of our civic authorities to the unhealthy as well as unsafe condition of the tenements of the working classes here, the pertinacity with which different forms of zymotic disease haunt certain unsavoury localities having convinced such philanthropic persons of the importance of remedial measures, whilst recent events have shown the danger from actual collapse which exists in not a few instances. The coroner's jury, in the case of the house that last fell, has returned the following verdict:—"Anna Maria Flynn was accidentally suffocated by the fall of the house No. 16, South Great George's-street, on the 6th of October, 1875, and there is no evidence to enable us to say what caused the fall of the said house." To this they added: "We desire to express our deepest commiseration for the poor inhabitants of this house, who have lost every vestige of their property by the accident, and we consider their case one eminently deserving of assistance towards relieving their distress." As this is the second house that has fallen within a short time, and as the engineer of the corporation has stated there are a good many houses which ought to be taken down altogether, it is to be hoped that a step which is so evidently necessary for the public health and public safety will be taken without further delay.

The improvement rate and the main drainage of Dublin also at present occupy public attention.

Zymotic disease continues to hold its own in those parts of Dublin where neglect of sanitary matters and superstition favour its course; thus a large number of individuals have been attacked in a neighbourhood where a wake was lately held upon the remains of a child. The same neighbourhood, too, is notorious as being the site of Maclean's-lane, where every form of noxious filth is collected by numerous manure-mongers, some of whom have been fined by the City sanitary authorities, and ordered to relinquish having all depôts within the City bounds. Much difficulty and delay were encountered by the Corporation in inducing the magistrates to inflict fines, because the Corporation itself carries on a traffic in the manure line on a most extensive scale in localities where epidemics of zymotic disease have exhibited great intensity. From time to time loud protests have been entered by hospital physicians and others against the continuance of these civic depôts so far in vain. This matter deserves special attention just now, because it is rumoured that the Corporation have allowed the continuance of the nuisances in Maclean's-lane provided coal ashes be mixed with the offensive matter.

Dublin, 19th October, 1875.

Medical News.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Oct. 14th :—

Collier, Herbert, Bohemia House, Turnham-green.
Ellis, Joseph Watson, Willingham, Cambs.
Flood, John, Penton-street, Islington.
Mathias, James, Penycoed, Blanenyffos, S.W.
Norris, Richard Hill, Birchfield, Birmingham.
Walmsley, Francis Henry, Higher Broughton, Manchester.

The following gentlemen passed the Primary Professional Examination on the same day :—

George Farncombe Blake, Queen's College, Birmingham ; Robert. Alex. Jackson, University College ; William Semple Merriman, Manchester Royal School of Medicine.

MR. WILLIAM EBDEN, Surgeon, of Haughley (who was deputy to the late coroner), is a candidate for the vacant Coronership of the county of Suffolk.

AT the quarterly meeting of the Directors of the Naval Medical Compassionate Fund, held on the 12th inst., Sir Edward Hilditch, Inspector-General, in the chair, the sum of £90 was distributed among the various claimants.

THE Royal Aquarium and Summer and Winter Garden Society's second ballot for the election of Fellows was held on the 18th inst. Seven hundred and fifty-nine ladies and gentlemen came up for election, of whom five hundred and ten were duly elected.

THE Royal Commission to inquire into the practice of subjecting live animals to experiments for scientific purposes met at 13, Delahay-street, on Tuesday. There were present—Viscount Cardwell, Mr. W. E. Forster, Sir John B. Karslake, Mr. T. H. Huxley, Mr. J. Eric Erichsen, Mr. R. H. Hutton ; and the Secretary, Mr. N. Baker.

COLLEGE OF PHYSICIANS, IRELAND.—At a meeting of the College, held on the 18th inst., the following office-bearers were elected for the ensuing year :—President: Samuel Gordon. Vice-President: Lombe Atthill. Censors: Lombe Atthill, A. W. Foot, Thomas Hayden, J. W. Moore. Registrar: J. Magee Finny. Treasurer: Aquilla Smith. Examiners in Midwifery: Fleetwood Churchill, jun., and E. B. Sinclair. Professor of Medical Jurisprudence: Robert Travers. Representative on the General Medical Council: Aquilla Smith. Librarian: Hugh J. Fennell.

KING'S COLLEGE, LONDON.—The following Scholarships and Exhibitions have been adjudged at the opening of the academical year :—1. Science Exhibition (open) given by the Clothworkers' Company, to J. F. W. Silk. Special Extra Exhibition, W. P. Root. 2. Theological Department: Resident Studentships to F. H. A. Hawkins, H. B. Hyde, and E. R. Hayne. 3. General Literature and Science Department: Freake Exhibitions to C. H. K. Harper and T. F. Hobson. 4. Applied Science Department: Freake Exhibition to H. Nettlefold; College Exhibitions to J. P. Kirkman, D. S. Marjoribanks, and J. L. Rigden. 5. Medical Department: Warneford Scholarship to Norman Dalton. 6. Whitworth Exhibitioners: G. C. Marks, Denis McDonnell and F. H. Norvill (equal), W. J. Tilbrook, and William Walker.

NORTHERN COUNTIES' ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—The autumn meeting of the Association was held in the St. John's Library-room, Keswick, on October 6th. The chair was occupied by the President, R. Elliot, M.D. (Carlisle). The following gentlemen were nominated for election :—As Member: J. Mackie, L.R.C.S., Medical Officer of Health, Darlington (R.S.D.). As Associates: J. W. Eastwood, M.D., Dinsdale Park ; G. H. Philipson, M.D., and Luke Armstrong, M.D., Newcastle-upon-Tyne; A. A. H. Knight, M.D., Keswick. After the completion of the routine business of the meeting, H. J. Yeld, M.D. (M.O.H. Sunderland), was elected President-elect of the Association. The following papers were read :—"On the results to be expected from the carrying out of the Artisans' Dwellings Act," by Dr. H. J. Yeld; "On the Powers and Duties of Medical Officers of Health," by Dr. J. M. Maclagan (M.O.H. Hexham R.S.D.); "Notes on Food-Inspection," by Mr. Henry E. Armstrong; "Two Years' Experience of the Cockermouth Village Closet System," by Mr. J. M. Fox.

Medical Appointments.

ANDERSON, G. H., M.D., has been appointed Certifying Factory Surgeon for Lofthouse, Yorkshire.

ARMSTRONG, L., M.R.C.S.E., has been reappointed Medical Officer of Health for the Dawlish and Wolborough Urban, and the Newton-Abbot Rural, Sanitary Districts: £400 per annum for two years.

ASHBY, A., M.B., F.R.C.S.E., has been appointed Medical Officer of Health for the Spittlegate Urban Sanitary District.

BASKERVILLE, J. D., L.R.C.S.I., has been appointed Honorary Surgeon to St. Bartholomew's Hospital, Chatham.

BREDIN, J. N., L.R.C.S.I., has been appointed Surgeon to the Ancient Order of Foresters, No. 4168, vice Sankey, resigned.

BRODIE, M., L.R.C.P.Ed., L.R.C.S.Ed., L.M., has been appointed Medical Officer and Public Vaccinator for the No. 2 District of the Bellingham Union, Northumberland, vice Sutherland, resigned.

BUCHANAN, W., M.R.C.S.E., has been appointed Honorary Surgeon to St. Bartholomew's Hospital, Chatham.

BULLMORE, W. K., M.D., M.R.C.S.E., has been reappointed Medical Officer of Health for the Falmouth Port Sanitary District for six months.

CLARKE, T., M.D., C.M., L.M., has been appointed Assistant Medical Officer to the Workhouse, Brownlow-hill, Liverpool, vice Hamilton, resigned.

CLAYTON, R., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Accrington District of the Haslingden Union, Lancashire, vice Gillespie, deceased.

COLMAN, T. J., M.D., M.R.C.S.E., has been appointed Public Vaccinator for the whole of the Parish of St. Philip and Jacob, in the Clifton Union, vice Evans, deceased.

CORBET, D., M.R C.S.E., L.M., has been appointed Medical Officer of Health for the Kidderminster Urban Sanitary District at £50 per annum for five years.

DE LA MOTTE, P. W., L.R.C.P.Ed., L.M., M.R.C.S.E., has been appointed Medical Officer of Health for the Swanage Urban Sanitary District.

DUFFEY, G. F., M.D., F.K.Q.C.P.I., has been appointed Lecturer on Materia Medica in the Carmichael School of Medicine.

DYKE, T. J., F.R.C.S.E., has been appointed President of the newly formed Society of Medical Officers of Health for South Wales and Monmouthshire.

GADDES, T., L.D.S., has been appointed Assistant Dental Surgeon to the National Dental Hospital.

GRAY, F. A., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer of Health for the Honiton Rural Sanitary District.

GRAY, J. R., M.B., C.M., has been appointed Medical Officer for the Knayton District of the Thirsk Union, Yorkshire, vice Buchanan, resigned.

HART, P. N., M.B., C.M., M.R.C.S.E., has been appointed a House-Physician to the Queen's Hospital, Birmingham, vice M'Queen.

HAY, Mr. J. H., has been appointed House-Surgeon to the Dumfries and Galloway Royal Infirmary, vice Scott, resigned.

HEALY, M. J., L.R.C.S.I., L.K.Q.C.P.I., L.M., has been appointed Medical Officer, Public Vaccinator, Registrar of Births &c., and Sanitary Medical Officer for the Monasterboice Dispensary District of the Drogheda Union, vice Callan, appointed to the Workhouse and Fever Hospital, Ardee Union.

M'BRIDE, J., L.R.C.P.Ed., L.M , M.R.C.S.E., has been appointed Medical Officer for the No. 2 North District of the Clifton Union, vice Evans, deceased.

MAC QUEEN, T., M.B., C.M., has been appointed a House-Surgeon to the Queen's Hospital, Birmingham.

MALONE, M. J., M.D., F.R.C.S.I., has been appointed an Examiner in General Education at the Royal College of Surgeons in Ireland, vice Tweedy, whose appointment has expired.

MEAD, Mr. G. O., has been appointed Assistant House-Surgeon to the West Sussex, East Hants, and Chichester General Infirmary and Dispensary, vice Gibbons, resigned.

MONCKTON, W., L.R.C.P.Ed., M.R.C.S.E., L.M., has been appointed a Medical Officer of the Rugeley District Hospital and Provident Dispensary, and of the Rugeley Convalescent Home.

MOORE, J. B. G. G., L.R.C.P.L., has been appointed Medical Officer and Public Vaccinator for the No. 1 District of the Ongar Union, Essex, vice Markby, resigned.

MORTON, R., M.B., F.R.C.S.I., has been appointed an Examiner in General Education at the Royal College of Surgeons in Ireland, vice Woodhouse, whose appointment has expired.

MOSS, C., M.R.C.S.E., has been appointed Administrator of Anæsthetics to the National Dental Hospital.

RANKINE, Mr. J., has been appointed Assistant House-Surgeon to the Dumfries and Galloway Royal Infirmary, vice Lorraine, resigned.

RAWSON, W. F., L.R.C.P.Ed., L.R.C.S.Ed., has been reappointed Medical Officer of Health for the North Bierley Urban Sanitary District: £70 per annum.

ROBERTSON, J. D., M.D., L.R.C.S.Ed., has been reappointed Medical Officer of Health for the Penrith Urban Sanitary District: £75 per annum.

ROSSITER, D., M.R.C.S.E., has been reappointed Medical Officer for the Leverton District of the East Retford Union, Notts.

ROW, C., L.R.C.P.Ed., M.R.C.S.E., L.M., has been appointed Medical Officer for the No. 6, or Lostwithiel District of the Bodmin Union, vice Blewett, resigned.

SANDIFORD, T. H., M.D., C.M., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Kilshannig Dispensary District of the Mallow Union, Co. Cork, vice White.

SAUNDBY, R. M., M.B., M.R.C.S.E., has been appointed House-Physician to the Royal Hospital for Diseases of the Chest, City-road, vice Bennett, whose appointment has expired.

SCOTT, R., M.B., C.M., has been appointed Medical Officer to attend Patients of St. Mary's Hospital and Dispensary for Women and Children, Manchester, at their homes, vice Richardson, resigned.

SHORLAND, E. P., M.R.C.S.E., has been appointed Certifying Factory Surgeon for Westbury, vice G. Shorland, M.R.C.S.E . deceased.

STEDMAN, F., M.R.C.S.E., has been appointed Certifying Factory Surgeon for Castleton, Derbyshire, vice Haslewood.

SUTHERLAND, W., L.F.P. & S. Glas., L.R.C.P.Ed., has been appointed Medical Officer and Public Vaccinator for the No. 6 District of the Bellingham Union, Northumberland, vice Brodie, resigned.

SYMPSON, T., F.R.C.S.E., has been appointed an Honorary Surgeon to the Lincoln County Hospital, vice Snow, deceased.

Births, Marriages, and Deaths.

BIRTHS.

DIVER.—On the 11th inst., at Yateley House, Caterham-valley, the wife of E. Diver, M.D., of a daughter.

GIBBS.—On the 12th inst., at Barham House, Harrold, Beds, the wife of Robert Gibbs, M.R.C.S.E., L.S.A., of a daughter.

ROGERS.—On the 14th inst., at Stanford-road, Kensington, the wife of H. Rogers, M.R.C.S.E., of a daughter.

SCHÖN.—On the 13th inst., at Warley Lodge, Brondesbury, the wife of J. E. Schön, M.R.C.S.E., of a son.

TIZARD.—On the 10th inst., at Weymouth, the wife of H. Tizard, M.D., of a daughter.

WEBB.—On the 13th inst., at Northleach, the wife of Hugh G. Webb, L.K.Q.C.P.I., of a son.

MARRIAGES.

DODD—PERKINS.—On the 13th inst., at Laughton, Leicestershire, Alex. Russell Dodd, L.R.C.P.L., M.R.C.S.E., of Seymour-street, Portman-square, to Mary, daughter of Joseph Perkins, Esq., of Laughton House.

HART—PRESTON.—On the 13th inst., at St. James's, Belfast, Wm. Hume Hart, M.D., to Margaret Adelaide, daughter of John Preston, Esq.

DEATHS.

DICKSON.—On the 13th inst., at Harmondsworth, Slough, Robt. Dickson, M.D., aged 70.

HARRISON.—On the 9th inst., at Sumner-terrace, Onslow-square, John B. Harrison, M.R.C.S.E., late Surgeon-Major Bengal Army.

HEYGATE.—On the 12th inst., at Hanslope, Bucks, Thos. Nicholas Heygate, M.R.C.S.E., aged 64.

HUNT.—On the 13th inst., Wm. James Hunt, M.D., M.R.C.P., Medical Superintendent of the Hoxton House Lunatic Asylum.

JOHNSON.—On the 15th inst., at Cavendish-place, Edward Johnson, M.D., aged 60.

LUSH.—On the 18th inst., at Weymouth, Ann, wife of Wm. Geo. Vawdrey Lush, M.D., for six years Sister Mary, and for twelve years Sister Elizabeth, of St. Bartholomew's Hospital.

MACPHERSON.—On the 8th inst., at Craven-hill-gardens, Geo. G. Macpherson, late of the Bengal Medical Service, aged 76.

ROBERTSON.—On the 3rd ult., at Kelso, John Robertson, M.D., aged 54.

ROBINSON.—On the 15th inst., John E. Robinson, L.R.C.P.Ed., of Westville, Rotherham, aged 27.

WATMOUGH.—On the 8th inst., at Pocklington, Yorkshire, Isaac Watmough, M.D., aged 66.

WILLIAMS.—On the 12th inst, Edward Williams, M.D., of Pendoylon House, Glamorganshire, aged 57.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

THE BUDGET OF THE HOSPITALS OF PARIS.

THE budget for 1876 has been published. For the year 1875 it was £1,180,000; for 1876 it will be only £980,000, being a diminution of £200,000. This is owing to the completion of extensive works undertaken in 1875. The actual income of the hospitals amounts to £529,000, hence the Board requests from the municipal body a grant of £447,600. In 1875 the grant amounted to £448,800, the difference being £1200. The Board consider that about 3200 children will in 1876 be received and treated in the Foundling. The former has also the charge of about 30,000 children being brought up in the country at the expense of the Board. The insane of Paris will cost in 1876 £160,600.

An Enquirer.—The Crown nominees on the General Medical Council, as at present constituted, consist of the following members:—Dr. Sharpey, Dr. Parkes, Dr. Quain, Sir Wm. Gull, Dr. Begbie, and Dr. Stokes. On referring back we discover that two vacancies will occur during the forthcoming year. Dr. Sharpey's term of office will expire in May, and Sir Wm. Gull's in June, 1876.

Dr. R. J. Metcalfe's letter shall receive attention in our next issue.

ACTION OF METALLIC ZINC ON NITRATE OF SILVER.

PROF. CORRADI has proposed, after an ulcer or wound has been cauterised with nitrate of silver, to touch the spot with metallic zinc. The caustic action is thereby increased, and from a minute study of the phenomena it is concluded that nitrate of zinc is produced. M. Jullien, deputy professor at the Faculty at Nancy, introduced this method at Lyons, after a journey to Italy; and M. Jules Chéron, Surgeon to the St. Lazare Infirmary of Paris, has just published a paper on the subject. This paper has been the subject of an article in the *Lyon Médical* (Oct. 17th, 1875) by M. Aubert. M. Chéron has applied this method especially in fungating syphilitic ulcerations. 18 patients treated by the nitrate of silver aided by the zinc were well in 9 days on an average; whilst 23, on whom the acid nitrate of mercury was used, took on an average 29 days to recover; and 26 patients treated simply by rest, inert applications, and baths, averaged 59 days before they were well. Of course such data are rather vague, as it is not said whether all the patients had the same *internal* remedies. It may be observed that the stick of zinc immediately applied to the locality touched with the nitrate of silver produces a black coloration, which is owing to a chemical change, the nature of which is a subject of controversy. M. Aubert, as we stated above, considers that a nitrate of zinc is formed; and hence he proposes, considering the success obtained, to substitute the latter salt for the nitrate of silver, which is expensive and apt to stain the linen and fingers.

G., (London.)—We never recommend a particular physician or surgeon.

AN APPEAL.

To the Editor of THE LANCET.

SIR,—In your issue of the 7th of August you were good enough to publish the following appeal:—

"I respectfully invite the attention of the medical officers of the public services to the following particulars of a sad case.

An assistant-surgeon, whose name it is not, perhaps, necessary to give, but which can be given to any subscriber who desires to know it, lost his health in the Crimea, and, after a lingering illness, died from softening of the brain, leaving a widow and five children in circumstances of extreme destitution. This officer's ill-health was not brought on by imprudence or bad habits. Those who have interested themselves in this case, and whose names are given below, know that his habits and conduct were always such as to command the respect of his friends. It must also be added that he made such provision as he could for his family by insuring his life in the Army and Navy Insurance Office, afterwards amalgamated with the 'European.' It is useless to add that no benefit was derived from this insurance, as this Office disastrously failed. When this occurred the state of the assistant-surgeon's health was such that a second insurance on his life was impossible. For several years before his death he supported his wife and family, and met all the expenses of his long illness, on his half-pay of 8*s.* a day. Not having served for ten years, his widow is not entitled to a pension.

"It is proposed to raise a sum of money for the purchase of an annuity for the benefit of the widow, who at this time depends on the charity of her neighbours for daily bread for herself and children.

"The following gentlemen will be happy to receive subscriptions in aid of this fund:—Major-General Lewis, Shirley, Southampton; Lieutenant-Colonel Begbie, Shirley, Southampton; Dr. Parkes, F.R.S.; Surgeon-General Longmore, C.B.; and Surgeon-General W. C. Maclean, C.B., Royal Victoria Hospital, Netley.

"I am, Sir, your most obedient servant,
"Netley, 30th July, 1875." "W. C. MACLEAN, M.D.

This appeal has been most kindly responded to, and I have to announce that Messrs. Atherley, Hankinson, and Darwin, Bankers, High-street, Southampton, who have been good enough to take charge of the fund, have in their hands the sum of £178 19*s.*, contributed for the purpose indicated in the appeal. I have acknowledged in every instance the receipt of contributions, with the exception of the sum of 5*s.* in postage stamps sent by H. P., R.N., whose address I did not know, and who wished his "mite" to be acknowledged through your columns.

The sum mentioned above is not inconsiderable, but it is quite inadequate to meet the requirements of the case. I have been advised that my appeal was published at the most unsuitable time of the year, when all the world is on the move, and when many professional men are abroad seeking relaxation. I, therefore, venture to ask you to give space in your columns once more to my appeal on behalf of this widow and her children.

I am, Sir, your obedient servant,
Royal Victoria Hospital, Netley, Oct. 19th, 1875. W. C. MACLEAN.

F.R.C.S.—1. An examination has just been held, and the next will take place on June 13th, 1876.—2. Parkes; Wilson; Local Government Board Medical Reports.—3. We cannot give an instance at present.

Dr. Woodward.—We cannot insert copies of letters addressed to other papers.

Mr. W. Story is thanked for his communication.

PALLIATIVE TREATMENT OF ULCERS.

To the Editor of THE LANCET.

SIR,—On reading in the "Notes" &c. of your valuable journal of the 2nd instant a communication from Mr. Rendle on the "Palliative Treatment of Ulcers," two inquiries occurred to me. 1st. Does Mr. Rendle mean that from *two* to *three and a half* grains of acetate of morphia dissolved in five drachms of water are to be applied to the ulcer at one time? 2nd. How often is the application of the charcoal dressing to be renewed? and is the solution of morphia to be used at each dressing of the ulcer?

If your correspondent would kindly take the trouble to answer these inquiries, he would greatly oblige, Yours truly,
Leicester, Oct. 14th, 1875. AN OLD PRACTITIONER.

A Model Seaside Watering-place.

The *Leeds Mercury* reports that it is projected to build at Salt Dean, a few miles east of Brighton, a model village, to consist of small houses, suited to the means of artisans, clerks, and others whose means are limited; such houses as might be let at rents which should commence as low as 5*s.* a week. There can be no question as to the great boon which such a seaside village would prove to the class for whose benefit it is proposed to be erected. At present the only way that is open to the working classes to visit the sea is by availing themselves of the cheap day excursions on bank and other general holidays; and we entirely agree with our contemporary in believing that in the majority of cases these long and fatiguing single holidays to Brighton or elsewhere do more harm than good, even when the fatigues of the day do not lead, as they so often do, to excess of drinking. A holiday to a working man, whether he work with his hands or his brain, to be a beneficial holiday, should be more or less a day of rest; and a day excursion to the seaside can never in any sense be called a day of rest. This proposed new watering-place is not only to be cheap, but the construction of the houses is to be as nearly perfect, so far as sanitary appliances are concerned, as recent knowledge on the subject renders possible. Places for public worship and for recreation, as well as reading-rooms, are to be provided; but, following the example of the Shaftesbury Estate, no public-house is to be erected. If this scheme should ever be carried out and become an established fact, its public utility will much depend upon its treatment by the London and Brighton Railway Company. Want of liberality shown by this Company to the public is, however, again improving the prospects of a new and competing line to Brighton, which, for a time at least, would be a great boon to the metropolis.

Mr. L. Tomlin.—We would advise our correspondent to advertise.

Mrs. Rusher's Convalescent Home.

To the Editor of The Lancet.

Sir,—It is possible that Mr. Morton's ill-advised letter may have the effect of drawing public attention to the special merits of the Dover Home, as it differs in many important respects from other institutions established for convalescent purposes.

It was Mrs. Rusher's desire in originating the Home to divest it as much as possible of the rigid discipline which is thought necessary for the successful working of most public institutions, and to render it a home in the strictest sense of the word—a place where the inmates would meet with the social comforts of domestic life, with the minimum of restraint essential to a well-ordered household. That she has succeeded in her laudable object, no one who has visited the Home can for a moment doubt. I have had occasion to send hundreds of individuals of both sexes to the Home, and they have spoken in the highest terms of the kindness they have received, and of the admirable manner in which the business of the establishment is conducted. The Home, which was formerly the old Ship Hotel at Dover, was kindly granted for its present use by the Directors of the London, Chatham, and Dover Railway. It contains accommodation for upwards of a hundred inmates, and during the summer months it is fully occupied by the industrious and sickly poor, who, on the recommendation of a clergyman or a medical man, are received on payment of a weekly charge, varying from 7*s.* to 9*s.*, according to sex. One special feature in the management is the facility given to members of the same family to enjoy together the privileges of the seaside. A man and his wife in shattered health, or a mother with a sickly child or two, may be accommodated in a separate room; but all dine at the same table, or at separate tables in the same room, for there is no class distinction. With our experience of similar establishments, it is not easy to reconcile this freedom of intercourse and economy of management, in which this institution stands pre-eminent, with administrative success; but the explanation is obvious to anyone who takes the trouble to inquire into the matter for himself. It will be seen that the lady who first founded the Home not only contributes much of her private income to its support, but that she also resides on the premises, combining in her own person the multifarious offices of lady superintendent, secretary, treasurer, and head nurse, watching over her charge as the one aim and object of her life. While other establishments depend for their support on the patronage of the rich, and spend a considerable portion of their income on incessant appeals in the daily press, it is refreshing to meet with one which has never advertised its claims, and to see how much can be done by patient self-denial and individual energy properly directed.

I am, Sir, yours &c.,

Guy's Hospital, Oct. 19th, 1875. J. C. Steele, M.D.

Fatal Catheterism.

The French pharmacien as well as the British pharmaceutist is apt to prescribe, and even at times to undertake surgical operations. At Bordeaux, a short time ago, a man suffering from stricture applied to Mr. B., a pharmacien of the place. He at once sent his son to the patient, and the young gentleman immediately sounded him so roughly that he died in a short time. A post-mortem examination was ordered by the authorities, and extensive urethral lacerations were found. The case will be sent to the sessions.

A. H. B. is entitled to his fee, and would have a good chance of getting it by suing in a County Court. It has often been granted. Sometimes it has not.

"On a New Urethrotome for Internal Urethrotomy."

We have received the following communication from *Dr. Patrick H. Watson*, but too late to append to his paper published this week in another part of our columns:—

> "The draughtsman has not done justice to his pattern, as he has not made the different sizes of the thick and slender parts of the staff sufficiently distinct, nor the transition of the one into the other as abrupt as it is in the actual instrument."

Dr. J. Cheeseman.—1. Decidedly unwholesome.—2. Unfit for food.

Life Assurance and Medical Fees.

The London Life Association object to pay to medical men the customary and very legitimate fee. The proposer is furnished with a printed form in the shape of a letter to his medical attendant, requesting him to supply the Office with minute details of the proposer's health. The latter is requested to sign the letter and forward it to the surgeon. By these means the Office has the information, and leaves the medical man to seek remuneration from his patient. We know of two instances in which the surgeon declined to accept any fee from the patient, and sent back the form to the Office, with the promise that it would be filled up if the proper fee were forwarded. In each instance the Company chose to do without the information, and accepted the life.

Mr. B. Walker's paper has been received, and will be published.

Maunsell Memorial Fund.

The following additional subscriptions have been received on behalf of the above:—

Subscriptions will be received by Dr. Joseph Rogers, 33, Dean-street, Soho, London.

How not to do it.

The papers contain a curious inquiry into the cause of death of one Stephen Walker, aged eighty-one, which admirably illustrates the way in which some people, in reasoning often, as well as in practical life, manage to overlook that which is readiest and nearest at hand. The poor old man was found by his son and daughter hanging from the staircase. They were too frightened to cut him down, and ran for a policeman. The constable went for a doctor instead of himself rendering prompt assistance, and the doctor on arrival severed the rope, but found life extinct.

Dr. Hugo Senftleben is thanked.

Dresses for Nurses.

To the Editor of The Lancet.

Sir,—In the very kind notice you gave of my paper on "Sick Nursing" in *Chambers's Journal* of the 11th of September, you expressed an opinion as to *print* dresses being better than what I advised—namely, black merino or lustre, as a dress for the sick-room.

Will you permit to say that there appear to me to be two strong objections to cotton dresses: first, they show every stain with glaring distinctness; secondly, they are a chilly sort of garment to sit up in all night. There is no necessity for a plain black dress to look gloomy, since a white collar and cuffs and a bright knot of ribbon at the throat obviate that at once.

Several papers have, I find, followed suit in discussing the very important subject of conduct and dress in the sick-room, and various objections have been made to the dress worn by our various sisterhoods. Now, I think those who make these objections do so in ignorance of the many *strong* reasons that exist for the adoption of a distinctive dress in such cases, and the idea that there is any dislike among the poor to the sister's sombre attire is quite erroneous; on the contrary, I have myself seen several instances where the outward appearance of the sister has carried weight, commanded respect, and caused advice to be listened to and acted upon, which I am convinced would have been otherwise neglected. On one occasion I was accompanying a friend who wore the sister's dress on an errand where time was valuable. We went by the Underground, and when the train came up every carriage was full, crowded with working men returning to their homes. The guard shook his head, and evidently considered our case hopeless; but no sooner did my friend appear at the door of a third-class carriage than the working men expressed in homely but forcible language a determination she should find a seat; for who knew but she was going to some "poor sick crittur or another?" So two of the men stood for the rest of the journey, and tried to make her as comfortable as circumstances would permit, evidently showing a certain amount of deference to me, simply because I was in such good company.

I remain yours &c.,

London, Oct. 14th, 1875. Bertha Leith Adams.

The Colchester Union.

This union is in some embarrassment by the resignation of Dr. Brown, the medical officer of the second ward. The medical officers of the remaining wards decline to take the duties permanently, and the other medical men of the place show no disposition to take them at all. In these circumstances the other medical officers are to be asked to do the duties for a month on their own terms. Would that scarcity of medical service were a little more common.

Oculus.—We do not know the gentleman's present address; but a letter addressed to the India Office would reach him.

"Schools for Scarlet Fever."

Our contemporary and good friend, *Punch*, publishes a few observations this week under the above heading, which are founded on a recent letter of "A Medical Man" in the *Standard*, complaining of the ignorance and ill-directed zeal of School Board visitors. It is argued that for "hyper-zealous visitors" not to know the dangerous nature of scarlet fever and other infectious diseases is ignorance quite as criminal as any which, when it kills people, juries find to be manslaughter. We commend our contemporary's remarks to the consideration of School Board officials.

B. H. H.—If our correspondent will refer to a Parliamentary Return relating to appointments of medical officers of health and inspectors of nuisances, published during the session 1873, and to be procured for a few pence at Hansard's or through a bookseller, he will there find all the known facts upon which answers to his questions can be based, and will be able to form his own opinion.

Army Medical Service.

To the Editor of The Lancet.

Sir,—It seems to me a pity that the grievances of a certain number of medical officers of the army should have been represented in Parliament as pertaining to the whole department, whereas a large proportion of it has no grievances to represent. This, I think, I can easily point out. In the first place, the juniors, or those who entered the service after the publication of Mr. Cardwell's Warrant in 1873, have nothing whatever to complain of. They entered under certain terms, which they were aware of, and are bound to abide by them, and Government has every right to obtain her servants at the lowest market rates. In the next place, the seniors, or those who came into the service prior to the publication of the Warrant of 1858, are certainly in as good a position now (if not better) with regard to pay and allowances as they would be under the old terms, and, in my opinion, they have reason to be thankful for being allowed the forage allowance of their rank, which was not at first guaranteed to them.

With reference to the remaining portion of the department, or those who were enticed into the service by the terms of the Warrant of 1858, which terms Government has latterly thought proper to repudiate, I presume it was the grievances of these officers Dr. Lush kindly endeavoured to lay before the House; and as Mr. Hardy's reply on the subject was most evasive, I trust that those concerned will not allow the matter to rest. It is of little consequence to us whether Mr. Hardy can or cannot procure doctors for the army under existing rules. I can most positively state for my own part that on such terms I never would have entered Her Majesty's service.

The loss of forage, including a groom, amounts to at least £60 a year, and is no trifle in these times of high prices and costly living, to say nothing of the indignity it entails, which is only equalled by the derogatory position of a medical officer when sent to march with a regiment of cavalry, and provided with the horse and equipment of a common soldier. It is hard to expect that we can be respected in the service when Government does not respect us.

The restriction put upon sick leave is utter ruination to the unfortunate whose health breaks down from climate or service, and I submit that it can justly be applied *only* to those officers who entered the service after it became a rule, and were aware of its existence.

In case our rights are still withheld from us, I would suggest that a fund be raised by those interested, with the view of obtaining the opinion of Sir Henry James on the subject, as I have been informed by high authority that it is not in the power of the Secretary of State to deprive officers of the privileges secured to them by the terms of a Royal Warrant.

I remain yours &c.,

Loongabhudra, Sept. 10th, 1875. A Grievance-walla.

New Sanitary Periodical.

We have received the two first numbers of the *Journal d'Hygiène*, lately started at Paris by Dr. de Pietra Santa. It is to be published twice a month, and to comprise climatology, mineral waters, winter resorts, sea-bathing, and epidemics. This is certainly a wide range, and, judging from the first numbers, we may look forward to much information on the subjects just named.

A. J. K.—The charge is not excessive. Something will depend on circumstances, such as previous custom, number of visits, &c.

Sea-sickness.

To the Editor of The Lancet.

Sir,—In Dr. Wilks's letter on Sea-sickness, he refers to a cause which coincides with an opinion I formed (from actual observation) on the same subject many years ago. It is this, that after the upheaval of the vessel by the action of the sea, the sudden sinking, as it were, of the deck, and the feeling of having the ground or support slipping from under you, produce that peculiar and horrible sensation through the spine and sinking at the epigastrium and faintness that result in sea-sickness.

Now, the remedy for this, which I practised with complete success on one occasion in a very rough passage from Rotterdam to London, is *to carefully attend to the motion of the vessel, and to accompany in your mind*, even by a slight stooping or pressing downwards of the body, the sinking down of the vessel's deck. It is well known that many sailors, when first starting on a voyage, suffer from sea-sickness, but soon get over it. I believe they as well as others who are good sailors do so by acquiring what may be almost called a new sense, that of closely following the movement of the vessel both physically and mentally, or through the nerves, and that this ultimately becomes so instinctive that sailors are not aware of exerting such a faculty. I shall be glad if anyone seeing this would try this simple and, I believe, efficacious remedy. I may add that during my voyage I felt very qualmy, and only kept off sickness by assiduously practising the above manœuvre. Nor could I stay any time downstairs, but always remained on deck.

Yours &c.,

Bristol, Oct. 18th, 1875. R. M. Ellis, M.R.C.S. Eng.

P.S.—The faculty is similar to the one acquired by the mason and builder and the chamois hunter, who are accustomed to look down fearlessly from a height which infallibly produces giddiness, a sense of danger and of falling in those not used to it.

To Young Ladies.

The following advertisement was cut out of the *Western Gazette*. The construction of the paragraph is somewhat involved, and, in spite of its delightful frankness, it is not quite clear whether Mr. Young is most anxious to get an increased practice or to secure a wife:—

> "I, Charles Young, Surgeon, requiring a wife, seek a larger practice. If I cannot leave advantageously, I hope to remain."

We have no doubt there will be quite a rush of young ladies and patients towards this interesting advertiser. The profession in the district, though, might wish him to "leave advantageously."

A Nurse.—We really do not know.

"Cheap Doctors."

To the Editor of The Lancet.

Sir,—My letter in your journal of October 2nd did not pretend to be an exposition of *how* to establish a dispensary, but a defence of its existence; hence your objection to its incompleteness placed at the foot of the letter of "M.D." in your last week's issue is devoid of point, as my letter could not be "incomplete" in a direction in which my arguments were not aimed. I have much pleasure in supplementing that letter with this further one, and in saying the mode I adopted to establish my dispensary was to let all patients know it as they came to me, and the institution grew with time. I charge 1*s.* for seven days' attendance at my place, and 3*s.* when I attend at patients' homes. In all cases I insist on prepayment, and will not go without, unless I know my people. I make all comers provide their own bottles or pay for them, come for their own medicines, and attend at my hours, from 10 to 12 A.M., and from 7 to 9 P.M. (Sundays excepted, on which day I see only those out-door cases that are very ill). These arrangements obviate all collection and attendant expenses, which latter with me are limited to drug bill and assistant. It will be found advisable to head the dispensary letter or card with the day of the week, as constant endeavours will be made to crowd two Mondays or Saturdays, as the case may be, into one week. This trick is then detected at a glance. The letter or card serves to prescribe upon, and is retained by the patient, as in out-door hospital practice. The working of a dispensary is also much assisted by the establishment of a pharmacopœia; for if my prescriptions had to be made up at the moment, the work would be immense and much delayed, and I have always found expedition a great element in success, as the poor have but little spare time, and quickness prevents crowding and its unpleasant aroma.

Yours obediently,

London, Oct. 11th, 1875. S.

Aneurism of the Pulmonary Artery.

To the Editor of The Lancet.

Sir,—The following brief case seems to me to be noteworthy, as I am informed that there are only two cases of aneurism of the pulmonary artery on record.

Walter D——, first mate of a ship, had a dispute with one of the seamen, which ended in a violent struggle between the two. They were twice separated, and twice broke away again in continuance of their fight. During this the seaman was seen to draw a knife and stab his opponent, who shortly afterwards became pale, staggered, and expired in a few minutes.

At the post-mortem examination, which was made the next day (June 12th, 1873), I found no external marks of violence, except a small incised wound, about an inch and a quarter in length, on the upper and outer part of the front of the chest on the left side. It did not extend to the cavity of the chest. On opening the chest, an extensive collection of coagula and liquid blood was found, and on further examination a small aneurism of the pulmonary artery perforated by a somewhat ragged hole.

The mate was described by one of the witnesses examined at the inquest as being a "very excitable man," and there can be little doubt that the excitement of the struggle produced the fatal result.

I am, Sir, your obedient servant,

Yokohama, Japan, Aug. 5th, 1875. W. Buckle.

Typhoid Fever at Gunislake.

To the Editor of The Lancet.

Sir,—The outbreak of typhoid fever at Gunislake, as reported in the *Western Morning News* of the 19th instant is substantially correct, but exaggerated. The greater number of cases, which are of a mild type, are near the main outlet of the drain, which is of glazed earthenware, and broken some distance from its end. This drain was flushed by a stream of water, which, from some accidental cause, was perverted from its course; hence the sewage, slop-water, &c., soaked into the soil, and at my visit emitted sickening effluvia. This will be immediately remedied. The village, as reported on former occasions, is in a very unsatisfactory condition.

Yours obediently,

R. Eliot West,

Tavistock, October 20th, 1875. Medical Officer of Health.

P.S.—The water was analysed a few months since, and found to be uncontaminated. It will be again examined forthwith.

Uncertified Deaths.

Dr. Goldie, medical officer of health for Leeds, in his last monthly report to the Sanitary Committee of the town, alludes to this subject in the following words:—

> "I am anxious to mention some facts with regard to those deaths not certified. First, you will find them chiefly amongst children under the first year of life, and the characters of those diseases which are generally put down at 'hap-hazard' as the causes of the deaths are either diarrhœa or some convulsive disease. Those certificates are generally from chemists and unqualified practitioners. And here let me show that chemists and such like persons are not altogether to blame for this. The analysis of the whole secret I find is this: That mothers generally endeavour to treat the cases at home, either from a pecuniary motive or a total indifference to the troubles of their young. They allow the disease to sap the constitution till they see danger and death near at hand; then they run to the first shop at hand with the sign of a druggist over its door, very anxiously seeking assistance, when neither the ordinarily skilled chemist nor the most erudite physician in the world could do anything that would stop the child from dying. Medicine, however, is given, and the deluded mother (consoled that she has done something towards the cure, which she cannot have been anxious about) returns home. Her child dies, and the only person able to give her a certificate of death is this unfortunate chemist. Now what I wish to show is that this chemist is not to blame, but the people themselves. They don't wish any better result than death, but only that they should be screened from an inquest. I would have every one of the cases uncertified made the subjects of a most careful inquiry before the coroner."

Erratum.—In our article last week on the "Recognition of Sanitary Medicine," in the fourth line from the top of the second column, page 566, for "Cambridge," read "London."

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from — Prof. Bentley, London; Dr. G. Johnson, London; Prof. Maclean, Netley; Mr. Savory, London; Dr. B. W. Clinical Lecture
ON
FEIGNED "ERYTHEMA GANGRÆNOSUM."
(A CASE OF MALINGERING.)

Delivered at University College Hospital,

By TILBURY FOX, M.D., F.R.C.P.,
PHYSICIAN TO THE DEPARTMENT FOR SKIN DISEASES.

Gentlemen,—From time immemorial diseases of various kinds have been simulated amongst all classes of society. As has been well said, "the monarch, the statesman, the priest, the soldier, and the criminal have alike feigned mental and bodily infirmities for the advancement of their own ambitious or nefarious designs," whilst others have found, in such deception, the ready means of exciting pity and of securing charity, or extorting claims unfairly. Very many feigners suffer from ill-health, or are the subjects of hysteria or morbid habits, manners, or tastes, and, indeed, are such as one may fairly expect would be likely to be under the influence of the stimulus to morbid actions. In some instances, however—and I shall bring under your notice to-day, as I believe, an instance of the kind,—individuals feign diseases who are *apparently* quite healthy in mind and body, and without there being seemingly any kind of motive or object in their so doing.

There are not many skin diseases which are feigned. Malingerers generally copy the pustular or ulcerative diseases, since these may be readily simulated and kept agoing at will by the application of local irritants. The case which I wish to speak to you about now was one in which a number of semi-gangrenous spots were developed in different parts of the body, and which, I doubt not, were produced by the patient herself. The disease answers to what has been termed erythema gangrænosum, which I have always regarded with grave suspicion, at least in almost all cases, as a feigned disease. Here are the notes of the case.

Previous history.—Patient has been a general servant without interruption since February, 1874. She is single, has lived well, and is well clothed. She has been in one situation only since she went out to service; the house is dry and very open. Has lived in London or its suburbs all her life. She is short for her age, and rather stout, of lively disposition, pale and sallow complexion. She has four brothers and one sister all healthy. Has had good health, is well nourished, and strong. Last December had dropsy, which lasted about a month. Has never had rheumatism or scarlet fever.

Present illness.—On Thursday, August 20th, she first noticed a long red patch on the front of the lower part of her left leg, about three inches long and an inch wide. This itched a great deal both day and night. On Friday, the 21st, she found a scab formed over the outer part of the patch, leaving a narrow red rim round it. A short time after the appearance of this first patch, five others were seen, one on the left cheek, a second on the back of the left hand, a third on the outer side of the right thigh at the junction of the lower and middle thirds, a fourth on the back of the left forearm about two inches below the elbow, and a fifth to the inner side of the first patch on the left leg over the tibia, and to its inner side, about the lower part of the middle third of the leg. All the patches formed on the same day. The chief patch is over the left mamma; this first showed itself towards the evening of the 20th as a scarlet patch about 4 in. by 4 in., the lower border being about an inch and a half above the nipple, the outer border reaching the anterior margin of the axillary fold, the inner border being about half an inch outside the left margin of the sternum. On the 21st (Friday), on waking, she found that the patch on the breast had become broken up into irregular patches of white, dead-looking skin, surrounded by a reddish halo. Over the parts of the patch which did not become red a slight, thin, brownish-yellow crust formed, as of eczema. About eleven of the white patches have formed altogether on the breast. Since then patient has not noticed any material change in appearance. On the 21st she discovered that the white patches were anæsthetic.

On the 25th of August the patient presented herself at the out-patient department, with a condition of skin as already described. The health is good; patient does not complain of pain, discomfort, or malaise. Menstruating at the present time; began to-day. Over the left mamma, extending over the area just described, is a mottled irregular patch of redness, consisting of many (five or six) isolated patches of various sizes. In each of the smaller patches are one or more depressed dead-white areas, surrounded by a red halo, the intensity of redness being greatest at the edge of the white patches, and fading abruptly at the periphery into the healthy skin. The breadth of the halo varies in different parts; in some cases it is not more than about one line, while at other parts it is two, three, or more lines. The redness of the halo fades a little on pressure, but does not disappear. In some parts there is a wider extent of redness than above described, where the skin is covered with a brownish-yellow crust, as is seen in ordinary eczema or in the later stages of herpes.

The depressed white patches are anæsthetic. The patient can feel, when pinched, to the extreme inner margin of the halo, but loses all sensation immediately the white patches are touched. The white patches feel decidedly colder than the healthy skin. Temperature taken and found to be higher than in other parts. Even over the areas of redness minute white anæsthetic spots may be detected, the size of some of the spots being not larger than millet-seed. In all the parts of the skin that are not white the patient has sensation, although even in the red parts the feeling is perceptibly diminished as compared with the adjacent healthy skin. All the other patches of the body furnish similar results.

It may be observed that all the affected parts lie on the left side of the body except the patch at the lower and outer part of the right thigh, the parts affected being the left mamma, left forearm, left hand (back), and left leg and slightly the left cheek, and, as just said, the lower and outer part of the right thigh. The patch on the right thigh is general, diffused, about 3½ in. in its largest (horizontal) measurement, and about 2 in. in the vertical measurement, the anæsthetic patch within this being 1¾ in. horizontally and 1¼ in. in its greatest vertical direction. On the front of the left leg are three streaky patches, the innermost one being about 1¼ in. long and ⅛ in. broad, and situated at the lower part of the middle third of the leg, just behind the inner edge of the tibia; this runs obliquely downwards, inwards, and backwards. Side by side with it is another patch about an inch long, and varying from a line to ⅕ in. in width. Nearly the whole of the skin on these patches is white and anæsthetic, there being only a narrow red halo, about a line in length, round them. The remaining patch in this situation is six inches long, but is not quite continuous, there being a break of half an inch at the lower part of the middle third; its width is half an inch above the break, one-eighth of an inch below. The lower portion runs obliquely outwards, downwards, and backwards, in the direction of the external malleolus; the upper portion is vertical, and on the inner side is an irregular portion of white anæsthetic skin extending at the upper and lower ends more than half-way across the patch, in the middle for about one-third of the distance; on the outer side there is a streak a quarter of an inch wide, which is partially anæsthetic, but is of a mottled appearance; between them there is a portion of skin which is red, but which retains its sensibility. The lower segment of this patch below the break is white and anæsthetic, surrounded by a red halo a line in width. The general appearance of these patches, taken collectively, gives the idea of some strong corrosive liquid having run down the front of the leg and caused the skin to lose its vitality. On the back of the hand is a circular diffused patch three-quarters of an inch in diameter, the white anæsthetic portion within this being about the size of a large pea. On the back of the arm there is also a circular diffused patch an inch in diameter, the skin within this being dark red, but more or less anæsthetic. On the cheek there are a few irregular spots, which are anæsthetic; they are surrounded by a narrow red halo, which is not so distinct as round the other patches. The portions of skin which were yesterday of a dull pearly whiteness, have to-day assumed a greenish tint. Temperature of white skin taken on the largest patch on the mamma 94·4°; healthy skin, 92·8°.

Aug. 27th.—The patches have not altered much in character, except that the yellowish scabs on the left mamma are thicker. Patient slept well. Bowels open. Takes her food well. General temperature 98·6°; temperature of white patch on left mamma 94 2°; of healthy skin of right mamma, 92°. Heart examined and found normal. Urine acid, 1020, no albumen, no sugar. The patches are now of yellowish tinge, and not dead white, as when first seen. The patient states that the skin surrounding the patches is painful, and that it has always been so. Some simple ointment has been applied to the patch on the right thigh, and the patient says now that she feels over the part when touched. This part is now covered with a dark honey-coloured crust. Over some of the patches the cuticle is beginning to loosen. Repeat yellow mixture and simple ointment. Patient states that she already feels better after a few doses of the mixture, though she did not complain before of feeling ill in the least. A question as to this point was put on admittance.

29th.—On Thursday, the 27th, there being reason to doubt the truth of the patient's statements with regard to the loss of sensibility of the white patches, the patches on the front of her left leg, being obscured from her view, were touched four times in succession with the point of a steel pen on the same spot. Twice she said she felt, and twice she said she did not. This afternoon Mr. Tweedy tried the patch on the breast with a pair of sharp-pointed scissors, sometimes using one point, sometimes two. It was then found that when she could not see the part she made guesses at random, sometimes saying she could feel, and at others that she could not, though the same spot was touched in each instance.

Sept. 1st.—The cuticle forming the white patches on the front of the left leg which has been treated with spermaceti ointment has been shed, leaving deep sharp-cut ulcers, surrounded by slightly raised, red, inflamed margins. There is no material alteration in the patch on the left breast beyond a thickening of the yellow honey-like scabs. There is also a thickening of the scabs of the patch on the right thigh. The other patches appear to be dying away. The scabs on the left hand and forearm, and also on the cuticle forming the white patches in those situations, have come away, leaving in the place of the former a red blush, of the latter white cicatrices.

5th.—The white patch of cuticle on the left breast is evidently much thickened and hardened, and there is some amount of serum effused beneath it. The scabs are still thickening. Ordered quinine and iron three times a day.

8th.—The scabs on the breast have been shed, leaving a red blush. The large patch of white skin is still *in situ*, and has not changed its appearance.

10th.—The patch of white cuticle on the breast was yesterday rubbed off by the patient's dress, leaving a weeping surface of true skin, which has this morning scabbed over. The ulcers on the left leg are in much the same condition as on the 29th ult. They have been treated with opium and lead liniment since the 26th.

15th.—The scabs have all come away, leaving a red blush. The ulcers on the left leg are slowly healing up. To be dressed with red-wash.

23rd.—There is a red mottled appearance of the skin in the situation of all the sores, except those on the left leg, the ulcers of which are healing more rapidly. Patient discharged this afternoon.

Now, gentlemen, I will give you the reasons which induced Mr. Tweedy and myself to come to the conclusion that this was a case of self-induced disease, and not one of erythema gangrænosum.

In the first place, there was no evidence of any disturbance of the general health, such as would explain the local lesions. The girl at the date of the attack of eruption was apparently in excellent health; she had never been subjected to any deprivation or been placed under any insanitary influences such as might have induced a cachectic or morbid state of body. It is impossible to suppose that gangrenous spots could spring up idiopathically and extensively over the surface unless there were very serious disturbance of the nutrition of the body to account for it. In cases of undoubted erythema gangrænosum of the skin the patients have been rather moribund than anything else; the nutrition of the body has been profoundly altered, and the mischief in the skin has constituted only one of a series of phenomena indicative thereof. For instance, in certain paralytic cases, when death has not been far off, in cases of ossified arteries, in the instance of severe purpura, erythema followed by gangrene has been observed. But in the case I bring under your notice there was not to be found a jot or tittle of evidence of ill-health or malnutrition. It is true the girl had what she termed "dropsy" a few months before, but it is difficult to say what she meant by this term; it may have been swelling of the legs from anæmia; but, at all events, for some time before, and at the time of the attack of the disease in the skin, the girl was in good health, and erythema gangrænosum does not occur under these circumstances.

Secondly. The onset and course of the disease were not those of a gangrenous disease, but just those of severe blistering. The patches began by active hyperæmia, assumed the aspect of a vesicated surface, and not the livid sphacelated aspect of a gangrene, whilst a healthy reparative process was speedily set up in them. As before observed, patches of erythema gangrænosum often begin as purpuric or livid spots, and certainly not by active hyperæmia, which in the present instance was more like that induced by a local irritant, as was also the vesication, or what appeared to be gangrene; whilst the speedy advent of active repair indicated that the nutrition of the body was good. As soon as the patient came into the hospital and had no further chance of practising deception, fresh supposed gangrenous patches ceased to appear, and the whole of the diseased spots began to take on the healing process, which proceeded at a rapid rate. It was, indeed, the general aspect of the pathological changes, especially the exact similarity of the changes to those which occur in a severe vesication in a healthy subject (the whitened centre and the red halo around), which led us at once to suspect malingering; because it seemed to us clear that, if the disease were an idiopathic one, a state of nutrition which could induce so profound a change in the tissues as gangrene was altogether antagonistic to the occurrence of the most active reparative process. The fact of the existence of the latter, indeed, gave the lie to that of the former. The changes in the patches ran the course of those of healthy wounds, and hence the disease could hardly be idiopathic gangrene.

Thirdly. The distribution of the patches was very peculiar. They were all but one on the left side, and exactly in the sites most accessible to the right hand—viz., over the mamma, the cheek, back of the hand, back of the forearm, and over the front of the tibia. The patch on the right thigh was at its lower and outer part, or the place most conveniently reached by the hand. There was nothing in the shape of the patches to call for much notice, save that the patches on the left leg were long and narrow, the long axis of the patch corresponding to that of the limb itself; and, as stated in the notes, their appearance collectively gave the idea that some strong corrosive liquid had been allowed to trickle down the leg, and to have been diverted laterally on either side below, as would indeed occur if fluid of a certain character were allowed to flow down the front of the leg. The non-symmetrical distribution of the disease, its presence in the parts of the body most accessible to the hand, and the appearance of the streaky patches on the left leg, point to a simulated and not a real disease.

Fourthly. The statements of the patient with reference to anæsthesia conclusively showed that, at least, the patient knowingly deceived us in regard to certain features of the cases. You will remember the notes stated that at first it seemed to be certain that the white areas of the diseased patches were anæsthetic; but on further testing this point, whilst the patient's view was obscured, her statements were found to be contradictory and untrustworthy. This, of course, must be regarded as very strongly confirmative of my view of the case.

Fifthly. The effect of pseudo-physic in this case confirms me in the view I take of it. The patient was ordered some yellow mixture, and told she would have some medicine, whilst the wounds were dressed with the simplest unguent. After some few doses of the sugar-and-water, she expressed herself as feeling already very much better, the fact being that she had never complained of feeling in any way ill or unwell before, though she was expressly interrogated upon this point on admission, and subsequently. She, in fact, assumed that she was and had been ill, and was better after taking the medicine, whilst she had before expressly stated that she was quite well. This seemed again to point to deception, the patient having forgotten to act up to the *rôle* assumed on former occasions.

I do not enter into any other considerations. I think the above quite sufficient, and especially the pathological aspect, to show that the case could not have been one of idiopathic erythema gangrænosum, but a self-induced one. The difficulty of discovering any motive for the feigning of gangrene does not alter the matter at all.

If you ask me what irritant did the girl use, I answer candidly that I do not know. It is not unlikely that it may have been hydrochloric acid, which has been used to produce "white gangrene" of the skin.

I beg of you to be very cautious in dealing with instances of so-called erythema gangrænosum of the skin, especially in hysterical subjects. Why individuals should take a fancy into their heads to produce vesicated patches of disease here and there about their body may be difficult or impossible to determine, yet that they do so cannot be doubted; but whenever you observe a case of the kind, you will know it is not one of idiopathic erythema gangrænosum if it occurs in a healthy subject, is accompanied at its outset by active hyperæmia, by an absence of purpuric symptoms, and if the patches speedily undergo repair. In other words, a gangrenous condition is incompatible with the phenomena of acute inflammation and rapid repair; at least, this is my experience.

One word before concluding touching the moral treatment of the case. When you have detected a case of malingering, do not be too hasty to deal harshly with the patient. There may be some morbid state of mind in him or her, unappreciable to the ken of the physician, which impels the malingerer to his feigning. Therefore be tardy in treating him or her as a wilful misbehaver; the duty of the physician is to be kind under all circumstances, and never cruel.

NOTES OF FIVE CASES OF ARROW-WOUNDS (RECEIVED IN THE SOUTH SEA ISLANDS), TWO FOLLOWED BY TETANUS AND DEATH.

By SURGEON ALFRED CORRIE, R.N.

CASE 1.—F. S——, nineteen, seaman, a strong, muscular, healthy lad, was struck when on shore at Santa Cruz Island by an arrow (which is supposed to have been poisoned by being in contact for some days with a dead body in an advanced state of decomposition). The wound, a small punctured one of the scalp, extended down to the skull, and on passing a probe a roughness was felt about the bone in that particular spot; the arrow broke in the wound, but the broken bit was at once removed, and the wound immediately sucked and bathed by some of the seamen. The man was stunned for the time, but soon recovered himself; felt a little giddy and sick. Fifteen minutes after the accident, after he was brought on board, he was seen by the medical officers, the wound enlarged, well explored, nothing found, nitrate of silver applied, and a small quantity of brandy-and-water administered; patient ordered to keep very quiet.

The accident took place on August 12th, at 3.30 P.M. At 8.30, some five hours after the affair, the patient complained of nothing but a little headache and some pain about the wound.

Aug. 13th.—Passed a good night; vomited this morning; slight headache; more pain about wound; no chills; tongue coated with a white fur; bowels regular. Ordered water dressing to wound. Temperature 99·2°; pulse 64.—8 P.M. (some thirty hours after accident): No headache or vomiting; slept much during the day; taken food fairly; bowels been open. Temperature 99·6°; pulse 64.

14th.—Passed a good night; less pain in wound; no headache; states he feels better. Ordered some opening medicine, and linseed-meal poultice to remove eschar. Temperature 99·8°; pulse 68.—8 P.M.: A little discharge from wound; no sickness, headache, or rigors; bowels freely open; taken food well. Ordered to continue poultice. Temperature 98·4°; pulse 64.

15th.—Slept well; a little more discharge from wound; pain in part much the same; the wound was enlarged to give exit to any pus that might be there; taking food well; tongue clean; very slight constitutional disturbance. To continue poultice. Temperature 100°; pulse 80.—8 P.M.: Discharge coming from scalp; less pain in wounded part; taking food well; slept during the day; a little vomiting; no fever. Temperature 98·4°; pulse 60.

16th.—Still some discharge from wound, not much; passed a good night; no headache or sickness. To continue poultice. Temperature 98·8°; pulse 60.—8 P.M.: Much the same as this morning; wound redressed. Temperature 98·4°; pulse 60.

17th.—Wound discharging; general health good; sleeping and taking food well; bowels regular. To continue poultice. Temperature 98·6°; pulse 60.—8 P.M.: No change in patient. Temperature 98·4°; pulse 60.

18th.—Patient much the same as on previous day; wound discharging a little still. Continue poultice. Temperature 98·6°; pulse 56.—8 P.M. (sixth day of accident): Has complained during the day of stiffness about the jaws, unable to open mouth so freely as usual; some pain in swallowing; a peculiar expression of countenance as if suffering great pain, but complaining of none; no change in wound, no sickness or headache, taking food well. No signs of fever or any general constitutional disturbance. Temperature 98·4°; pulse 48, slow, but regular.

19th.—Patient slept well; complains of no particular pain about wound, but a nasty, unhealthy-looking discharge coming from it. A feeling of stiffness and soreness about the jaws and throat; unable to open mouth widely or protrude tongue freely, which is now covered with a dirty white fur; countenance assuming that peculiar expression of pain and anguish; features somewhat fixed; angles of mouth drawn down, constituting that appearance called the "risus sardonicus"; a general uneasiness of the whole body, and slight pain complained of about the dorsal region. No headache or sickness; slight thirst. Ordered beef-tea, jelly, wine, &c. Temperature 99·4°; pulse 60.—8 P.M.: Perfect trismus; can hardly separate teeth at all; much difficulty in swallowing, liable to bring on spasms of the facial muscles; more pain in cervical and dorsal regions; no spasms as yet of the lower extremities; slept some hours during the day; passed water freely; wound in the same condition; taken a fair amount of nourishment in the shape of beef-tea, jelly, wine, and brandy. Temperature 98·4°; pulse 56.

20th.—Patient very restless during the night, the spasms very slight; several doses of chloral hydrate were administered, and nutritious fluids given whenever the patient could take them. At 8 A.M. the patient got out of bed to be shifted, when a very severe spasm came on; the whole body was convulsed, the head thrown back and fixed by the powerful contraction of the muscles of the neck, the countenance pale and anxious, and greatly disfigured by the perverted action of the muscles; jaws firmly fixed; breathing short and hurried; the body became covered with profuse perspiration, and the patient greatly exhausted after the attack. Temperature 98·4°; pulse 80. Soon after this an enema of beef-tea and one drachm of chloral was given. The patient slept a little after this, but was disturbed by incessant twitching of the muscles.—At 10 A.M. another spasm came on, very similar to the one I have described.—At 1 P.M. another enema of beef-tea and chloral was given. Patient remained quiet after this, but did not sleep.—At 3 30 P.M. an injection of morphia was ordered hypodermically. He slept a short time after this, and on awaking stated that he felt better; able to open mouth a little more freely, and articulate with less difficulty; constant twitching going on in the muscles, but he had not had a severe spasm since 10 A.M.; the only thing he can swallow is jelly—taken several ounces of it. At 6 P.M. an enema of strong beef-tea, two ounces of brandy, and one drachm of chloral was given. The patient went to sleep soon after this, and slept soundly, with little or no spasmodic action until 8.30 P.M., some two hours and a half. He awoke refreshed, and took a small quantity of nourishment.—At 10.30 P.M. a severe fit came on, very similar to the one he had in the morning, but of greater intensity; the body suddenly raised; muscles of back of neck, trunk, and lower extremities powerfully affected; body regularly formed into a bow (opisthotonos); an expression of great mental distress and anguish in the countenance; jaws firmly fixed; the whole face greatly distorted and disfigured; breathing hurried and short; pulse weak and irregular; surface of body covered with profuse sweat; muscles of chest and abdomen felt like hard pieces of board. Patient fell back perfectly exhausted and gasping for breath. He was offered a variety of things in the shape of nutritious fluids; he could swallow nothing; a horrible dread if he took anything that another spasm would come on. Injections of morphia were given with no benefit, the spasms coming on with greater frequency and severity. Between the fits the body was hot and damp; temperature 104·6°; pulse rapid but weak; the slightest noise or movement brought on fresh convulsions.

At 6 A.M. of the morning of the 21st the patient was attacked with a final spasm; gave a sudden jerk, and was completely thrown off the bed; took two or three men to hold him during the fit; features assumed a horrible appearance, lips becoming blue; body fearfully convulsed; muscles rigid and tense. Death closed the awful scene.

The man died on the ninth day of the accident, and some fifty or sixty hours after the first signs of tetanus set in. The mind was clear from the beginning to the end, and there was no want of control over the bladder or bowels. Death appeared to take place from suffocation combined with extreme exhaustion.

(To be continued.)

NOTES ON A

CASE OF TUMOUR OF THE CEREBELLUM.

By RICHARD CATON, M.D.,

LECTURER ON PHYSIOLOGY, LIVERPOOL SCHOOL OF MEDICINE; ASSISTANT-PHYSICIAN TO THE INFIRMARY FOR CHILDREN.

On the 15th January, 1875, I was asked to see A. B——, a man somewhat under the middle height, of healthy appearance, aged twenty-eight, the manager of a large farm.

History.—About fifteen years ago patient had an attack of rheumatic fever, which was believed to have left behind it some cardiac affection, which, however, of late years had produced no symptoms of importance. Patient described himself as enjoying excellent health, and was apparently capable of active muscular exercise. About four months ago, when spending too much time in reading after his day's work was over, he suffered for a day or two from occipital headache. On discontinuing the reading this ceased.

Fourteen days before I saw him, having been somewhat short of labourers on his farm, he had helped the men to carry some distance, and to lift up a ladder, a large number of sacks, each weighing about 1½ cwt., the exertion being extremely severe. On that evening he was attacked by a violent pulsating headache in the occipital region. This had remained almost constant up to the time of my seeing him, and was so severe as to prevent sleep and render exertion impossible. He had had two or three attacks of vomiting.

Symptoms when first seen.—Severe pulsating headache in the occipital region complained of. Patient, who is a highly intelligent man, is quite clear intellectually, but is unable to bear much conversation, is very sensitive to noises, and suffers much from tinnitus. He exhibits some degree of difficulty and unsteadiness in walking; has no paralysis of motion or sensation; sight unaffected. He cannot recline on the back without increase of pain. Tongue furred; bowels constipated; no appetite; respiratory sounds normal; a remarkably loud, double aortic murmur; cardiac dulness perhaps slightly increased; pulse about 120, markedly aortic; temperature rather above the normal range; urine normal. He has always been strictly temperate, and has never had syphilis.

The *diagnosis* presented some little difficulty. I was in doubt between two theories—firstly, that of the existence of structural lesion of the brain; secondly, cerebral anæmia or some disturbance of brain circulation, due perhaps to mechanical injury of a previously diseased valve, sustained during the violent exertion on the day from which the symptoms dated. I rather inclined to the latter theory.

The *treatment* consisted in rest, the employment of counter-irritation over the nape of the neck, gentle aperients, and bromide of potassium, and subsequently iodide of potassium.

Progress of the case.—Coincidently with the treatment referred to, improvement took place in some of the symptoms. The headache, instead of being constant, became intermittent, the remissions became longer, and, finally, in about ten days the headache had become only occasional; any excitement or over-exertion would bring it on. The appetite returned. Notwithstanding improvement in these respects, great and increasing muscular weakness was observed; the muscles were largely developed, but the patient, who a fortnight ago had been capable of muscular exertion such as few of his farm labourers could surpass, now could not ascend two pairs of stairs without assistance. His gait began to be more unsteady; he could not turn round with the eyes shut without falling. Eyesight perfectly good, but a remarkable slowness in accommodation manifested itself. In adjusting the focus of the eye from an object one foot distant to another at fifty feet, a delay of three seconds took place. I measured this carefully on several occasions. The movements of the eyeball were normal; spectra in the form of blue rings were described.

These symptoms again excited fears of the existence of some structural lesion (perhaps of the cerebellum), and I decided to have a careful ophthalmoscopic examination made. Mr. Edgar Browne, surgeon to the Eye and Ear Infirmary, reported the presence of commencing optic neuritis about both discs, with dilated and tortuous vessels and one or two small hæmorrhages. This evidence was considered conclusive as to the existence of coarse disease, tumour, apoplexy, or abscess of the cerebellum being suggested. A very unfavourable prognosis was given. The eyesight as yet was quite good, but, notwithstanding appropriate treatment, the clouding of the retina was seen by us to spread steadily day by day, until at length, within about ten days from its first discovery, it produced loss of sight. About the same time the general symptoms became more severe, pulse and temperature rose, and occasional delirium occurred. Rheumatic symptoms were complained of, and pain in the loins drew attention again to the urine, which a few weeks back had been quite normal, but now was found loaded with albumen and containing numbers of granular tube-casts. Severe night-perspirations occurred; temperature often rose to 103°; pulse ranged from 110 to 130. The patient's hearing, which had formerly been morbidly acute, was now noticed to be defective on the left side. Several weeks now elapsed, during which no important change took place. Pain in the cardiac region and left hypochondrium were occasionally complained of. He suffered from a sense of oppression in the head, but only at intervals from headache, and was usually quite clear intellectually.

Towards the end of April, œdema of the legs appeared, and some fluid collected in the peritoneum. Occasional squint and signs of partial paralysis of the facial muscles of the right side became manifest. About the 1st May he began to have difficulty in expressing himself, on the 3rd became gradually hemiplegic on the right side, and died on the 4th.

Autopsy.—Cerebral hemispheres normal externally. A tumour, the size of a small walnut, was found on the under surface of the left hemisphere of the cerebellum, adjacent to the pons, and beneath the auditory nerve, which was stretched over it. There was a small embolus in the left middle cerebral artery, beyond its first anterior branch. The ventricles contained two or three ounces of fluid.

Remarks.—The sudden onset of the symptoms immediately after violent muscular exertion, valvular disease being present, was very misleading, and caused at first an error in diagnosis. Subsequently the diminution of muscular power without paralysis, the ataxia, together with the occipital headache and optic neuritis, formed a group of symptoms on the whole characteristic of tumour of the cerebellum. The affection of hearing gave, later on, a clue as to the probable locality of the tumour. The slowness of accommodation is a symptom which I have not seen described before. It was very marked. If the patient glanced up from the book he was reading towards the figure of any person entering the room, he described himself as only being able for two or three seconds to see a dim haze, then he saw quite distinctly. Changes in focal adjustment were obviously made slowly and with difficulty. Prof. Ferrier has shown how largely the cerebellum is concerned in the co-ordination of the muscles of the eyeball; has it a like control over the ciliary muscle and the mechanism of accommodation?

Liverpool.

EMPYEMA, FOLLOWING SCARLET FEVER: THORACENTESIS; RECOVERY.

By BENJAMIN WALKER, M.R.C.S., L.R.C.P., &c.

Sarah Jane W——, aged two years and a half, the child of healthy parents, was seized with convulsions on the 5th of April. The attack lasted about half an hour, and the left half of the body was chiefly affected, the left hand being very blue and the face much distorted. The left half of the body was quite powerless. Speech was not affected. On the following day the characteristic rash of scarlatina appeared. The nearest medical man was called in, and he attended her till the 16th, when she came under my care. This was the twelfth day of the illness. There was then considerable though not complete loss of power of the left half of the body; tongue dry and glazed; pulse 130, feeble and compressible; skin hot and dry. The temperature could not be taken at any time through the illness on account of the restlessness and fear of the child when approached. Throat affection slight. There was great thirst. The bowels had been freely opened by my predecessor. Bark and ammonia were now ordered, with beef-tea, egg, and brandy mixture at regular intervals, and, to quench the thirst, milk and lime-water *ad lib.*

May 1st. — Condition was one of hectic, with frequent flushings and rigors, and the child was greatly emaciated, the support being taken in a very desultory manner.

8th. — An abscess of considerable size under the left pectoral muscle was opened, and gave exit to about three ounces of fairly formed pus; there was a slight drain for a few days and then the discharge ceased. In the course of two weeks the left side of the chest began to increase in size, so that the measurement exceeded the right by about an inch; the heart was displaced to the right, so that the apex beat was to the right of the sternum, a little below and to the inner side of the right nipple. There had been a troublesome cough for three weeks past, latterly increasing in severity, but without much expectoration, till the 17th, when there was a copious discharge of pus tinged with blood, denoting the occurrence of bronchial fistula. Some relief followed this, and purulent matter was from time to time expectorated with the cough, in greater or less quantity; the chest measurement, however, was little affected, and the child continued in much the same state for the next six weeks, when the dyspnœa became daily more marked, and it was evident that, unless relief were obtained by other than nature's method, there would soon be a fatal termination, for the little patient was emaciated to an extreme degree and rapidly sinking from hectic.

July 15th.—With the assistance of my friend Mr. Foulds, who saw her in consultation, a medium-sized needle of Maw's bottle aspirator was inserted, between the sixth and seventh ribs near their angles, and 20 oz. of odourless pus of the consistence and exact appearance of pea-soup drawn off. A little blood commencing to flow warned us to withdraw the needle. The lung gradually expanded whilst the fluid was being withdrawn, as indicated by the cough, and afterwards verified by auscultation and percussion. No anæsthetic was used, and the operation was the simplest in performance, only a sharp twinge of pain being felt at the moment of inserting the needle. Immediate relief followed the operation; the breathing was easier, the cough less troublesome, and purulent expectoration ceased from this date. Next day the child was better, and there was no irritation or discharge at the seat of puncture, which was seen as a mere spot, and soon entirely disappeared. The relief, however, was but temporary; for in three days (the 18th) the distension of the pleura was as great as before, and the aspirator was again employed, and a little more than a pint of odourless pus similar to the former drawn off, with relief to all the urgent symptoms.

The exhaustive and able "Clinical Remarks on Tapping and Draining the Pleura," by Mr. Berkeley Hill, appeared in The Lancet just at this time (July 17th), and I derived practical benefit from the excellent rules there laid down.

The purulent effusion again distended the pleura, displacing the heart as much as before, but more slowly. The condition of the child was one of extreme emaciation, the limbs being apparently little more than bones covered with skin. The two aspirations having yielded perfectly inodorous pus made me unwilling to insert a drainage-tube; but, as she was evidently sinking, with the assistance of my former colleague, a trocar and canula was introduced, which gave exit to about a pint of similar pus. The opening was then enlarged, and a No. 9 Holt's winged catheter introduced. Through this a pint more, at a moderate computation, gradually drained in the next twenty-four hours. The end of the tube was surrounded by a loose pad of tenax to absorb the discharge, and this changed daily. The steady improvement inaugurated by this operation showed it to be the correct one. The child lost all its former hectic and febrile symptoms, and began to take nutriment in almost any shape in which it was offered. In the course of a week or two the appetite was ravenous, and chops and steaks were disposed of in a manner which would certainly have taxed the digestive powers of a healthy adult. Sleep became sound and refreshing, the child awaking once or twice in the night, only to ask for food. In addition to solids, large quantities of milk, and of egg and port mixture, were disposed of in the twenty-four hours. The cough and expectoration both disappeared, and in a month's time she was as plump and firm-fleshed as ever in her life. The increase in the girth of her limbs could almost be graduated daily.

Aug. 28th.—Began to take cod-liver oil emulsion, and, in addition to bark, Parrish's syrup.

At present (Oct. 20th) the discharge from the tube varies, some days being very slight, others more profuse, the weather influencing this in some measure; besides which, the house in which the patient lives is very damp. She runs about as in health, and on fine days goes into the air.

Remarks.—The advantage of giving free and permanent opening in empyema, at whatever age occurring, is clearly exemplified by the result of this case. The milder operation of removing the fluid by aspiration is less repugnant, especially in so young a patient; but the reaccumulation in so short a time as three days, with its accompanying hectic, shows that it is but tentative; and on a similar case recurring I should advise drainage after a first aspiration, as giving a better chance of recovery than a repetition of the less severe operation, regardless of the state of exhaustion of the patient.

The subject of antiseptic surgery is again coming to the front, as appears from a leader in The Lancet of the 16th inst.; where there is also recorded (at p. 577) a case of Mr. Pemberton's, at Birmingham, in which "extremely successful results" have been obtained in a case of empyema, "where the chest was opened antiseptically and a drainage-tube run through it, the man having gained weight in a remarkable manner." I think, without any invidious comparison, this little patient shows that equally satisfactory results may be obtained, with care and cleanliness, without antiseptic surgery.

I would also say a word in favour of the simple and inexpensive bottle aspirator of Messrs. Maw and Son, which acts most efficiently. The winged catheter makes an excellent drainage-tube, though it is well to attach it by a thread secured by a strip of diachylon, as, if the wings alone be trusted to, the tube may escape (as occurred once to me), and give some trouble in its reinsertion, especially in a very young patient.

The parents will be most happy to show the child to any practitioner desirous of seeing it.

Spondon, Derby.

NOTES OF SIXTEEN CASES OF ABORTION.

By JOHN DOUGALL, M.D. Glasgow.

(Concluded from page 588.)

Case 12.—Mrs. E——, aged twenty-four, in third month, second abortion, second pregnancy, on a journey from London to Glasgow by railway, became ill soon after leaving Carlisle, but bore up till her destination was reached. She had lost a deal of blood, the result of which was obvious in her feeble polycrotic pulse, exsanguine lips, and anæmic features. An ounce of brandy was at once given, the shoulders lowered, and the pelvis raised. The os was slightly open, and what seemed a portion of ruptured ovum involucra hanging from it. As she was still bleeding, the vagina was stuffed with sponge wet with a solution of tincture of perchloride of iron, and warmth applied to the feet. She began to revive, but being too weak to bear any attempts at extracting the fœtal structures, I resolved to wait, and ordered beef-tea and wine with chicken broth and arrowroot. Next day she was much better; and had slept a few hours, though wakened several times by uterine pains. On withdrawing the plug it was followed by several large clots and fresh hæmorrhage. A cold astringent lotion was injected. The os was somewhat open, but no projecting body felt. The plug was again used successfully, and the extruded coagula were carefully searched, yet no traces of embryo or membranes were seen. That night the plug was once more removed, but had to be replaced. Next day I proposed to give chloroform and explore the uterus, but patient and husband objected. Ergot, strychnia, and steel were prescribed, and for nearly a week the treatment was merely a repetition of the foregoing. Latterly the hæmorrhage so far lessened that the plug could be dispensed with. Astringent injections were continued for some days, when the discharge gradually assumed a lochial character, and ultimately ceased. Convalescence was protracted. She was in fair health and menstruating six months after.

Case 13.—Mrs. F——, aged thirty-two, in third month, first abortion, second pregnancy. I found her in a most perilous state from loss of blood, her features sunk and blanched, her extremities cold and pulseless; in fact, *in articulo mortis.* The vessel contained about half a gallon of blood, while a great portion of her bed and body clothes were saturated with it. As there were no stimulants in the house, I had to wait till some were procured. In the interval the pillows were removed from under her head and placed beneath the pelvis, and cold applied to the vulva and pubes. A friend having returned with half a tumblerful of whisky, she was at once made to swallow about three-fourths of it, while heat and friction were applied to the extremities. Either from nearly absolute depletion, or from general vascular contraction caused by the muffled and weakly flicker of the heart, or more likely from both, the hæmorrhage had spontaneously ceased before my arrival, or was easily arrested by the means stated. In a short time the radial and temporal pulses could be detected—quivering threads, and she answered one or two questions in monosyllables. A mixture of egg and brandy was now given in small and frequent doses, and in an hour after she was much improved; pulse 160. A vaginal examination now made showed the os uteri much dilated, and a round body protruding, which I slightly tried to extract, but failed. Next morning she was further improved. I liberated the body from the os, which proved to be a large black coagulum. For some days she was carefully fed and nursed. There was no more hæmorrhage, and, being naturally healthy and muscular, she made a rapid and uninterrupted recovery. No portion of the ovum was found.

Case 14.—Mrs. T——, aged twenty-eight, in seventh month, third abortion, third pregnancy. Is tall and heavy, but lax of fibre, anæmic, and weak. The night previous she had been doing some extra housework, though suffering from diarrhœa. I found her in bed, with the body of a dead female fœtus protruding from the vagina. The liberation of the head was only wanted to complete the birth, and was easily done, previous to which I gave ergot and borax in cinnamon water. The placenta came away easily, followed by considerable hæmorrhage. She progressed favourably till the thirteenth day, when pain commenced in the right inguinal region, with increased swelling and stiffness of the corresponding leg (her limbs were anasarcous previously), thirst, and headache—symptoms indicative of phlegmasia dolens. She was kept in the horizontal posture, with the affected limb raised, four leeches were applied to the most painful part, hot fomentations, liniments, and dry friction used, milk, wine, raw infusion of muscle, and chicken soup ordered, and a mixture of steel and strychnia prescribed. Under this treatment she improved, and was out of bed in three weeks. She then stayed two months in Arran. At present (eight months after her confinement) the limb is still much swollen. She complains of a dull and constant pain in the knee-joint, while her general health is obviously impaired.

Case 15.—Mrs. C——, aged twenty-six, in third month, first abortion, first pregnancy, married two years and a half, first consulted me in regard to general debility and leucorrhœa. She was much improved by a course of tonics and vaginal injections. Soon after she had a large vulval abscess, which discharged copiously and reduced her health considerably. She then had fistula in ano, and was operated on. After this she was put on steel and cod-liver oil, by which she laid on flesh very rapidly. I then advised her to stop the oil and continue to take ten minims of tincture of perchloride of iron thrice daily. About eight weeks afterwards she called to say she had missed two of her monthly periods. In less than a week I was requested to see her. She had been losing a little blood for two days, and had now bearing-down pains. "She was sure it was not because she had not taken the steel drops, as she had not missed a single dose." Though I had an idea that the iron might have contributed to causing her pregnancy, I now thought that her taking it after might be the cause of her aborting. The os was slightly open, but no ovum could be felt. Opium, digitalis, and sulphuric acid were prescribed, with light diet, the horizontal posture, and quietness. This treatment seemed successful, but next day the pain and bleeding returned, and the bag of membranes was felt dilating the os. Ergot was given, and, after four hours' severe suffering, the ovum was shed entire. She made a good recovery. The fistula was unhealed four months afterwards.

Case 16.—Mrs. B——, aged thirty, in fifth month, first abortion, fifth pregnancy. The previous evening she fell from a chair while adjusting some clothes on a rope. I found her on the verge of syncope from loss of blood and in great pain. On examination the membranes were found entire and beginning to part the labia pudendi. They were at once ruptured, as recommended by Prezos,* and almost immediately the fœtus was expelled by the breech. Ergot was given, and in five minutes the placenta was easily removed, hæmorrhage and pain quickly ceasing. Patient was up in a week.

Remarks.—Some points in these cases are common to all such, as the period when abortion took place, its cause, chief symptoms, &c. But there are others, illustrating certain doctrines in regard to abortion generally, to which the following remarks apply.

1. The removal of a retained ovum or placenta is effected in three ways: (*a*) by the giving of substances which stimulate the uterus to contract; (*b*) by the avulsion of the ovum or placenta with forceps, &c.; (*c*) by passing the hand into the vagina and the fingers into the uterus and turning out its contents. (*a*) Cases 1, 2, 5, 6, 7, 9, 10, 11 show that, whatever effect ergot or borax had in lessening hæmorrhage, they had little if any in causing uterine contractions. (*b*) The use of the ovum forceps, wire crotchet, &c., for dragging away the ovum or placenta is generally and justly condemned from the obvious risk of wounding the uterus. Only in Case 2 was the ovum forceps used and without benefit. (*c*) Cases 1, 2, 10 show that the placenta may be retained a considerable time without danger, also the success attending its removal by the hand in the vagina. In Case 10, where the placenta was adherent, and uterine stimulants failed, obviously no other procedure could have resulted nearly so satisfactorily.

2. There is a strong presumption that the cause of abortion in Case 4 was uterine flexion and adhesion prior to pregnancy. Madame Boivin found, in the course of her dissections, that in many of those women who always

---

* Rigby's Midwifery, p. 95.

aborted when they arrived at a particular period of pregnancy, the uterus had contracted adhesions with the neighbouring viscera and the general pelvic cavity.*

3. Plugging the vagina with sponge wetted with some astringent fluid was done nearly a dozen times with unvarying success, the speculum being used in most cases. While admiring the scientific manner of plugging with tangle, recommended by Dr. Barnes, I have found it comparatively difficult to perform; besides, it is necessary, so as to be sure the plug will keep *in situ*, to stuff the vagina with a portion of sponge, lint, or some such body, which of itself might be sufficient to prevent hæmorrhage. If this be omitted, it may be found that the tangle is expelled as soon as it begins to expand the os, from the uterine contractions thereby originated.

4. In Case 5 the action of the enema in stimulating uterine contractions was very marked and successful. This plan is well worthy of further trial in cases of retained secundines with hæmorrhage, in conjunction with other means usually employed.

5. Vaginal injections of hydrochloric acid, where the lochia seemed at all fetid, were often used. The mineral acids, being reliable disinfectants in small quantity, as distinguished from mere deodorants, should be used in all such cases.

6. In six of the cases it was attempted, without success, to save the ovum. The twice-recurring threatened abortion in the pregnancy succeeding abortion, in Case 6, shows, however, that even where miscarriage is imminent (provided there is reason to believe the ovum or fœtus is living) the means to avert it should be employed.

7. I am not aware of any recorded instance of the injection of iron alum into the uterus. The astringency of this salt is very great; and in Case 6, where it was frequently used, the effect was highly satisfactory. I find the uterus is more tolerant of internal medication than is generally believed; and in cases of chronic endometritis I have frequently injected solutions of iodine and chromic acid, and also have often introduced pure carbolic acid with the probe invented by Professor Playfair, and as recommended by him in The Lancet about two years ago.

8. The bracing effects of the atmosphere of certain places on the west coast of Scotland are well known. I have several times been struck with its curative influence on functional diseases of the female sexual organs, and have had at least four cases where some weeks' residence at the coast, along with other appropriate treatment, was soon followed by pregnancy after prolonged sterility. Whatever favourable effect the compound syrup of phosphate of iron may have had in Case 8, the woman herself is convinced that she owes, in great part, her improved health and living child to a lengthened stay at one of the Clyde watering-places.

9. Case 14 is typical of a class not uncommon, where nature, in a cachectic habit, with its usual malign concomitants, makes frequent abortive attempts at reproduction. In such cases utero-gestation is often, in the same patient, brought to the verge of completion, when, from some cause, fœtal or maternal, not easily eliminated and difficult to avert, the vital process is suddenly blighted, and a premature still-birth results. The phlegmasia dolens which followed in this case could not arise from the usual cause, great hæmorrhage, as that was only considerable.

10. Whether the continued administration of iron during pregnancy in Case 15 helped to cause the abortion is questionable, but I have thought proper to record the circumstance. At a meeting of the London Obstetrical Society† Dr. Barnes alluded to an instance where a pupil of his had given iron to a pregnant woman, and was in consequence accused of intending to produce abortion. Dr. Barnes said he had given it in dozens of cases, and never witnessed any ill consequences, or instances in which abortion could be traced to its administration. He thought iron might safely be given where anæmia was present during pregnancy, to improve the patient's condition and lessen the risk of hæmorrhage during parturition.

11. The quantity of blood women lose in abortion and parturition is often very great, yet it is astonishing how quickly they generally recover. Cases 7, 12, 13, and 16 are marked examples. In view of this, probably bleeding might be had recourse to with benefit more frequently in acute diseases. The admirable address of Sir James Paget, chiefly on bleeding, at the Norwich meeting of the British Medical Association confirms the above. Amongst other things, he said: "At the present day we undoubtedly overvalue the blood, and estimate too cautiously the loss of it. The loss of blood to fainting is absolutely harmless." These remarks applied to healthy persons.

Glasgow.

ON A CASE OF

ANEURISMAL TUMOUR OF THE PHARYNX.

By JOHN J. BARNES, M.R.C.S.

I beg to call attention to the following interesting case.

B. N——, aged seventy-three, a female patient of mine, had complained of slight difficulty in swallowing. On looking into the throat I found it natural, with the exception of a small pulsating tumour, situated at the back of the pharynx, between the median line and the right posterior pillar of the fauces, but nearer the latter. It is about an inch in length and half an inch in width, the upper end being opposite the lower edge of the soft palate. The pulsation of this tumour is entirely arrested by very moderate pressure over the external carotid. Partly, no doubt, from the difficulty of getting a good *point d'appui*, it cannot be arrested completely by such pressure as my patient can bear over the common carotid.

Cases have been recorded by Porter and Syme of aneurism of the internal carotid "pointing" in the above situation. I think, however, from the extreme ease with which the pulsation is arrested in this case by pressure over the external carotid, that it is more likely to be an aneurism of the ascending pharyngeal branch of that artery. It is of course open to anybody to maintain that the pressure with which one arrests the pulsation is conveyed through intervening structures to the internal carotid. I can only reply that the pressure required is so moderate that it seems doubtful whether it would be sufficient to stop the flow through the internal carotid, considering its depth from the surface. There are no pressure signs; the pupils are equal; there is no alteration of voice; no dyspnœa. The only complaint is of occasional slight discomfort in swallowing, which amounts to very little. There is no evidence of aneurism elsewhere.

Considering the age of my patient, and that the tumour has not materially increased during the last three months, I do not feel justified at present in tying the common carotid. If the aneurism should increase, I think it would be right to give digital pressure a trial. In the event of any bleeding coming on, the patient's friends have been instructed how to compress the external carotid, which they can do perfectly. Tying the common carotid would then, I presume, be the only resource.

Bolton.

Doncaster Infirmary.—At the annual meeting of the governors and friends of this institution, held last week, a report was read which was satisfactory as testifying to the prosperity of the infirmary. Whereas last year there was a balance of £121 due to the treasurer, this year there is a balance of £54 in favour of the institution, whilst its supporters are becoming more numerous and influential. Its usefulness also had been shown in the aid it had afforded to an increased number of patients. A legacy of £3000 by the late Mr. Barker had been paid, and the combined results of Hospital Saturday and Sunday had enriched the funds of the infirmary to the extent of nearly £300.

Bequests, &c., to Medical Charities. — The Newcastle-on-Tyne Infirmary has received £2425 under the will of Mr. James Pigg. TheConvalescent Society, Whitley, has received £1000 under the will of Mrs. Blackwell. Mr. William Crook, of York-street, Portman-square, bequeathed £200 each to the Hertford Infirmary and the Worcester Infirmary, and £50 each to the Royal United Hospital, Bath, and the Harrowgate Hospital. Miss Sarah Goodin, of Maida-vale, bequeathed £200 each to the Surrey Dispensary, the London Hospital, and St. Mary's Hospital.

GUY'S HOSPITAL.

CASE OF EMPYEMA TREATED BY FREE EVACUATION OF THE FLUID.

(Under the care of Dr. Wilks.)

In the Mirror of the 14th December, 1872, we referred to some cases of empyema treated by Dr. Wilks by means of free evacuation of the collected fluids and by subsequent drainage. At a recent visit to Guy's Hospital we saw a case which illustrated in a marked manner the great benefit that is often derived from freely opening the chest in these cases. A thin delicate woman, aged twenty-one, but looking much older, was admitted on the 13th inst., apparently moribund. It was ascertained that the patient was quite well until eleven months ago, never having had any illness, except small-pox when a child. The father died of hæmoptysis at the age of forty-five, but the mother and the brothers and sisters are living and healthy. Eleven months ago the patient caught cold, and suffered from cough accompanied by pain down the sternum. This pain was always much increased by coughing. There were never any rigors, but there was some delirium at the commencement of the illness. For a month she attended the Southport Infirmary as an out-patient, but, becoming worse, she was taken into the infirmary, where she remained for six months, under the care of Dr. Seager. During that time she suffered great pain in the right side of the chest, together with cough and shortness of breath; and she stated that on one occasion she spat up about two quarts of blood. She was, however, better when she left the infirmary, but was unable to do any work. She remained at home four months, but, becoming much worse, was admitted into Guy's Hospital.

On admission she was thin and delicate-looking, and had very flushed cheeks, the expression of the face being pinched and almost peevish. The skin was hot and dry. The voice was feeble and husky, and there was a constant hacking cough. The nails were filbert-shaped, and the ends of the fingers clubbed. The ocular conjunctivæ had a pearly appearance. The tongue was white and moist; the gums were pale, and presented a red line at the base of the teeth. Just below the right mamma was a red, hot, tender swelling, and there was extreme tenderness over the whole of the lower part of the thorax from the spine forwards, and also over the liver, and, on deep pressure, throughout the whole of the abdominal region. There was dulness of the whole of the right side of the chest in front; below the third rib the dulness was absolute, and in this part there was entire absence of vesicular murmur. Above the third rib there was increased vocal resonance and tubular breathing. The left front was resonant throughout, the vocal resonance increased, and the breath-sound tubular. At the back on the right side there was absolute dulness, and absence of breath-sounds below the spine of the scapula. About this there were tubular breathing and increased vocal resonance. The left back was resonant, and the respiration sounds were exaggerated. The apex beat of the heart was diffused, and one inch below and half an inch outside the nipple. There was a cardiac bruit of a churning sound most audible at the apex. The patient suffered greatly from thirst. The temperature on the morning of admission was 103·5° F., in the evening 100°, respiration 36; bowels regular; urine sp. gr. 1012, no albumen or sugar. The patient had not menstruated for eleven months.

On the evening of the 14th an incision was made into the front of the chest, where the pus was pointing. A catheter was then introduced into the pleural cavity and made to point behind, where another incision was made. About sixteen ounces of fluid escaped. A drainage-tube was then put in, and the cavity washed out with a solution of carbolic acid (1 to 40). Next day the patient was decidedly better and looked brighter, and the temperature was normal. On the 16th both sides of the chest expanded fairly well below the clavicles. The right side was hyper-resonant in front but rather dull behind, with marked ægophony and very slight vesicular breathing. There was good resonance on the left side of the chest, both in front and behind. The breath-sounds were harsh, but vesicular just below the right clavicle; in the left front they were puerile. At the back the breath-sounds were bad on both sides. On the 19th the patient was still better, felt stronger, slept well, and the appetite was good. The cough also had ceased. On the 20th all signs of the inflammation had subsided from the surface of the thorax, and the tenderness was much less. The right chest was tympanitic on percussion, but very little air entered the lung. On the 21st the drainage-tube was withdrawn from the opening in front of the chest, and the washings, which had hitherto been performed daily, were now ordered to be done every other day. On the 25th (the day of our visit) the patient, although evidently still weak, was sitting up in bed unsupported, and stated that she felt stronger. The right subclavian region was resonant, and below this the chest was hyper-resonant. There was, however, no tactile vibration, although vesicular murmur could be heard at the inner half of the right subclavian region. At the back the right supra-scapular region was normal, but below this there was dulness with distant and feeble breath-sounds. There was fairly good tactile vibration. The temperature was normal, as indeed it had been since the tapping, but the respirations were still very frequent, being, at the time we saw the case, 38 per minute.

Remarks.—This case (for many of the notes of which we are indebted to Mr. Thomas Duke) is an example, by no means rare, of what may be done by means of tapping in even some of the worst cases of empyema. It is scarcely too much to say that in this instance life was actually saved by the procedure; at all events, it has been prolonged, and the patient put in a fair way for recovery. Nor is the case by any means exceptional. Free opening has been so uniformly successful in these cases that Dr. Wilks alleged that he would always recommend it in empyema, and experience has shown that this advice is in the main thoroughly sound. For, notwithstanding the adverse opinion of many of the older teachers, and even of many of the present day, it must be confessed that the lives of patients have been sometimes unmistakably sacrificed to the efforts made to save the lung. The practice of tapping has been again and again denounced as likely to damage the lung. In former times, even when the operation was sanctioned it was done with a sparing hand. A few ounces of fluid were allowed to escape, and then the puncture was firmly closed. But as the patient did not improve, the operation was repeated in the same niggardly manner several times, at longer or shorter intervals. After all, the patient too commonly died with a chest full of fluid, a large share of which was, not without reason, often attributed to the evil effects of tapping; whereas, if free evacuation had been ensured, the result would in all probability have been vastly different. When there is pus in the pleural cavity Dr. Wilks maintains that the lung is destroyed, and then it is useless to attempt to restore it to its natural state. There is, however, one exception to the universal adoption of tapping in empyema. Often in children large quantities of pus collect in the pleural cavity, but afterwards become entirely absorbed, leaving the lung practically unimpaired. In such instances to establish a communication between the outer air and the pleural cavity would not only be unnecessary, but might be attended with evil results, and lead to irreparable collapse of the lung.

ROYAL HANTS COUNTY HOSPITAL.

CASE OF SEVERE NEURALGIA IN THE TRACT OF THE RIGHT DENTAL NERVE; OPERATION; RECOVERY.

(Under the care of Mr. Langdon.)

For the following notes we are indebted to Mr. William Robert Smith, house-surgeon.

The patient was a nurse, who had for the last three years suffered from intense neuralgic pains in the face, occurring at irregular intervals, but generally caused by eating, drinking, or exposure to cold. The fits of pain were always preceded by a stinging sensation at the side of the mouth, then a feeling as if a number of hot irons were being thrust into the tongue, followed by the most severe pain, from the symphysis to the ramus of the jaw on the right side, and thence to the temple, spreading both backwards and forwards. During the two years that the patient had been a nurse to the hospital every medicine which was likely to give relief had been tried; but as the pain increased in severity, at the patient's entreaties that something more should be done, it was decided to divide the dental nerve. This was done on Sept. 1st An incision was made along the anterior margin of the masseter muscle, another at right angles to this along the body of the jaw, and the triangular flap of skin raised; the bone was then trephined with an instrument three-quarters of an inch in diameter, and the dental nerve and artery were thus exposed in their canal. About half an inch of the nerve was then removed. Troublesome hæmorrhage took place from the dental artery, but was arrested by the application of a red-hot wire. The edges of the wound were then accurately brought together by means of silver wire, a small opening being left at the apex of the angular incision for the escape of pus. Carbolic oil (1 in 30) was then applied.—8 P.M.: Feels very comfortable. Has had no return of the pain; been slightly sick once. Pulse 120; temperature 102 3°.

Sept. 2nd.—Slept fairly. No pain, but occasional headache. Complains of thirst. Pulse good; no sickness. The wound not dressed.

3rd.—Progressing favourably. No return of pain, but she complains of slight aching in the face. Bowels moved slightly. The wound was dressed with carbolic oil, and looks well, there being only a little watery discharge from the opening, whilst the ends of the incision are quite healed.

4th.—Slept well; complains of pain and stiffness just below the ear, this part being also red and hard; in other respects she is much improved, takes nourishment well, and feels in every way better. A bread poultice was ordered to be applied to the inflamed surface.

5th.—Last evening had severe twitching and stinging sensations, with pain just beneath the tongue and by the side of the jaw; this, however, did not spread over the face, as it had originally done, nor was the pain so intense.

6th.—Had rather a restless night, the twitching still continuing, but with less severity; wound discharging more; the redness and hardness beneath the ear decreased; general condition still in every way good.

7th.—Is much better; has had but a slight return of the twitching sensation; bowels rather confined; wound doing well.

From this time patient went on uninterruptedly getting well, until Sept. 14th, when she had a slight return of the pain. On Sept. 18th she left the hospital for change of air, the wound having nearly healed.

25th.—Patient feels quite well, much better than she has done for some time; has had no return of pain.

27th.—Patient discharged to duty.

The only treatment found necessary in this case was an occasional dose of castor oil; no anodyne was required. The wound was dressed with carbolic oil, with the addition, after a time, of a bread-and-water poultice; the nourishment consisted of milk, soup, beef-tea, pudding, and minced meat.

BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.

SACCULAR DILATATION OF THE URETHRA; REMOVAL; CURE.

(Under the care of Mr. LAWSON TAIT.)

MRS. B——, mother of a large family, had suffered for many years from a protrusion about the size of an egg from the vulva, which was excessively painful. She passed large quantities of fetid pus from the bladder. The protrusion looked like an ordinary cystocele, save that it was quite irreducible, was very hard, and when firmly pressed a large quantity of fetid ammoniacal pus escaped from the orifice of the urethra. If this pus got on the fingers it made them smart. The sound readily passed into the cavity of the protrusion from the urethra. It was clearly, therefore, not an ordinary cystocele, but probably a sacculation of the urethra, and the only benefit likely to be obtained was by its removal. She was placed under ether, and the lower half of the protrusion was removed by a cut of the scissors, and this opened into a large cavity lined with thickened corrugated mucous membrane. It had an opening into the urethra large enough to admit a No. 9 or 10 catheter, the opening being situated in the lower wall of the urethra, and about half way between its orifice and the entrance to the bladder. The whole of the mucous lining of the sac was removed, and the vaginal mucous membrane was closed over the cavity by deep sutures. The wound healed rapidly and the cure is now complete.

Mr. Tait remarked that he had never met with a case like this, and he supposed that the sac must have been of congenital origin.

REMOVAL OF A LARGE SOFT FIBRO-MYOMA BY ABDOMINAL SECTION; DEATH.

(Under the care of Mr. LAWSON TAIT.)

Mrs. W——, aged forty-five (sent by Dr. Eshelby, of Stroud), had been aware of an increase in size for about four years, but chiefly within the last few months. Mr. Tait saw her first at the end of July, and found a large semi-fluctuating tumour reaching up to the xyphoid cartilage, lying chiefly to the left side, but with a well-defined secondary mass lying under the liver. There was a good deal of ascites. The tumour moved very freely. The uterus was high, and moved with the tumour, but not closely enough to make it certain that it was not ovarian. Mr. Tait expressed a doubtful opinion about the nature of the tumour, but advised an exploratory incision, and the removal of the tumour if it were possible. The incision was accordingly made on Sept. 11th, and, even when the tumour was bared, it was not till a needle had been passed into it that its non-cystic nature could be definitely ascertained. The tumour was free from adhesions, and had a fair pedicle. Mr. Tait therefore removed it and placed a clamp on the pedicle. The tumour was found to be a collection of extremely soft fibroids growing in the fundus uteri, which was of course removed with them. The patient went on well for thirty-six hours, but died of general peritonitis on the fourth day.

This is the second case of the kind that Mr. Tait has operated on, the first having recovered.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE ordinary meeting of this Society was held on the 26th inst., Sir James Paget, F.R.S., in the chair. A paper by Dr. Greenhalgh, advocating the use of the actual cautery for the enucleation and removal of certain uterine fibroids was read. The difficulties in the selection of suitable cases, and the subsequent risks arising out of the disintegration of the growths were the points chiefly dwelt upon by Drs. Meadows and Barnes, who spoke on the subject. This paper was followed by one by Mr. Spitta, late Demonstrator of Anatomy at St. George's Hospital, explanatory of a new working model of the larynx, and containing a confutation of current opinions as to the actions of the respective laryngeal muscles.

Dr. GREENHALGH, at the commencement of his paper "On the Use of the Actual Cautery in the Enucleation of Fibroid Tumours of the Uterus," alluded to the infrequent use of the actual cautery as compared with its application on the Continent, and passed on to enumerate the cases in which, for the last twelve years, he had used it with more or less success. These cases include chronic enlargements, with induration of the cervix uteri, due to inflammatory or fibroid diseases; epithelioma and cancer of the neck of the uterus where the organ is movable; some cases of vascular tumour of the meatus urinarius; slight cases of recto- and vesico-vaginal fistula; in incontinence of urine due to dilated urethral canal, and in certain cases of interstitial and intra-uterine fibroid growths. It was to its use in the two latter classes of cases that he limited his present observations. Full notes of a series of five cases in which this operation was performed were then given. The following is a brief outline of this part of the paper.—Case 1. Forty-three years of age, married thirteen years, with six children; came under treatment for retention of urine in 1866. For three years there had been much vaginal discharge, and, latterly, menorrhagia. Examination showed a large elastic growth from the posterior wall and fundus of the uterus, reaching to within an inch of the umbilicus, and in the pelvis compressing the rectum. A trocar was introduced into the mass in the vagina, which was followed by jetting of arterial blood, only checked by means of the actual cautery. A profuse serous discharge followed, and four days later the cautery was again applied, and by degrees the tumour shelled out from its capsule through the aperture thus made. The tumour was of the size of the fœtal head at term.—Case 2. Forty-seven years of age, married twelve years, never pregnant. Came under treatment for difficulty in micturition and defecation. A large tumour, flattening the rectum, filled up the pelvis. It was opened in the most dependent part by the actual cautery. Death occurred from peritonitis, due to perforation of the intestine, and the tumour was found to have contracted adhesions with the cæcum and rectum, and to be ulcerating into these cavities.—Case 3. Thirty-eight years of age, married thirteen years, four miscarriages; a large tumour from the posterior lip of the os uteri obstructed labour. The growth was treated by the actual cautery. The tumour gradually enucleated, and the patient made a good recovery. [With reference to this case, Dr. Greenhalgh read a letter received from Mr. Marriott, of Leicester, stating that last month the patient was delivered safely of a full-grown child at term. Before the operation was undertaken, the posterior lip of the uterus used to enlarge during pregnancy, and on the last occasion premature labour had to be induced.]—Case 4. Aged forty-seven, married, never pregnant; suffered much from hæmorrhage, constipation, and difficult micturition. A large tumour occupied the hypogastric region; the os uteri was stretched over the growth. The cautery was used in all four times, and the tumour removed piecemeal, gradually disintegrating. The patient recovered.—Case 5. Aged thirty; came under treatment in August, 1874; had suffered from floodings since January. An enormous fibroid tumour occupied a large part of the abdomen, and below it projected into the vagina from the posterior lip of the uterus. The case was under treatment for several months. The cautery was frequently applied, and the mass gradually disintegrated. There was much putrid discharge, and constitutional disturbance. The patient died in February, 1875, from embolism, after the growth had been apparently in great part, if not wholly removed. The tumour weighed in all 7 lb. 1 oz. Thus of these five cases three were intra-mural, one intra-uterine, and one extra-mural. The author expressed an opinion that diffused fibroid deposits of the uterus in the early stage were more amenable to treatment than was generally supposed. Further, there were cases in which through the large losses of blood to which they gave rise, or the mechanical effects they produced, surgical interference was demanded. Dilatation or enucleation by the knife was sometimes employed, but this had been followed by ill effects, while the advantages of the actual cautery might be summed up as affording facility of application, causing but little pain, being rapid in its action, giving rise to no bleeding, and therefore obviating plugging; in the charred opening being unfavourable to absorption; in there being no offensive discharge from the charred surface; in the ready dilatation of the opening without bleeding; in permitting of manipulation through the opening immediately after its use. Lastly, by the use of the cautery, portions of the tumour may be rapidly destroyed, its size reduced and its lower segments rendered conical, thereby facilitating dilatation of the opening, and the subsequent detachment, expulsion, or removal of the morbid growth. Spontaneous expulsive efforts shortly followed its use, and the density of the tumour appeared to be more or less reduced. In conclusion the author drew especial attention to the three following points:—Firstly, the advisability of the gradual detachment of the growth from its surrounding capsule, especially in cases where the tumour is of large size or where the patient has been much reduced by previous hæmorrhage, by which further losses of blood are avoided and more perfect contraction of the investing tissues is secured, and the chance of pent-up offensive discharge is almost certainly prevented. Secondly, the removal of only so much of the tumour at each operation as is external to the opening, by which the opening is kept dilated, and all chance of its closure upon the remainder of the growth avoided. Thirdly, the speedy destruction by the cautery or removal by the écraseur or hand of the tumour, should sloughing ensue.—Dr. Meadows, while acknowledging that the method proposed was a valuable addition to the modes of treatment of fibroid tumours, pointed out the difficulties arising from its application owing to the variable amount of union between such tumours and the uterine wall, for whereas some were distinctly encapsuled, and could be enucleated with ease, others were intimately blended with the muscular fibres. It was difficult in practice to distinguish these cases. Then the cases in which the operation was applicable were those in which the tumour was strictly intra-mural, so that the uterine tissue might aid in the process of enucleation. This or any other operative measure was contra-indicated if the growth were close to the peritoneal or mucous surface. The difficulty in diagnosing the exact site of the growth was then a great hindrance to operative measures. The cautery was no doubt preferable to the knife, but as it frequently required the introduction of the finger to break down the attachments of the tumour, another element was introduced. The cautery *alone* would be almost free from danger.—Dr. Barnes concurred with Dr. Meadows in the difficulty of diagnosis of the exact nature and site of many fibroid tumours. Those springing from the cervix might fairly be treated by this method; but there was great risk in dealing with those arising from the fundus. One danger he especially insisted on was the tendency which these growths showed—after operations had been practised on them—to undergo a process of low necrotic inflammation, terminating in septicæmia; a course of events followed in one of Dr. Greenhalgh's cases. The actual cautery could not guard against this result, and he almost doubted if it were perfectly secure against the supervention of hæmorrhage. He was not then at all prepared to accept the use of the cautery, which much resembled the "gouging" process; and it could only be reserved for extreme cases.—Dr. Greenhalgh, in reply, pointed out that in his cases the cervix was involved in the growth. He would reserve the cautery for suitable cases, and would not employ it in subperitoneal tumours. He alluded to the soft semi-fluctuating character of some of the tumours, and the escape of serum that followed. If operative measures be undertaken, the cautery was the best means, for even dilatation was dangerous. Moreover, by the use of the cautery there was no interference with the cavity of the uterus, e.g., Case 3.

A paper was then read entitled "An original View of the Laryngeal Movements," accompanied by a new movable model, by Mr. E. J. Spitta. The model, which was designed as an aid to demonstration, was constructed of metal, the muscles being made of india-rubber. The following is a brief abstract of the paper:—"The model illustrates the present theory by exhibiting mechanically the two operations of the larynx under which all its movements may be included—namely, the *tensing* and *relaxing* the cords, and the *opening* and *closing* the glottis. The new view principally concerns the last-named operation. It shows, in the first place, from the construction of the crico-arytenoid joints, how neither forward nor rotatory movements of the arytenoids are possible, and that these cartilages can only move laterally, but that by this very movement the interval between the cords is horizontally increased and the glottis opened. It then describes the laryngeal muscles, and how they effect the two operations above-named, giving them fresh names in accordance with their actions: the arytenoideus, for example, is called the 'occludens,' and the crico-arytenoidei named the 'M. patulens.' Lastly, the new view adds a remarkable though totally unexpected corroboration of its truth, derived from the peculiarity in distribution of the laryngeal nerves."—Mr. Charles Brooke pointed out that in the model the membranous portion of the vocal cords was not represented, and referred to the experiments of Willis designed to show the part played by the membranous portion in vocalisation, sonorous vibrations only being produced when the upper portions of the membrane are placed parallel.—Mr. Nunn said that the real question at issue was as to the nature of the crico-arytenoid articulation. The action of the muscles must depend upon the peculiar arrangement of the facets of this articulation.—Dr. Whipham thought Mr. Spitta's views received confirmation from the appearances seen in the laryngeal mirror. He had never been able to perceive any rotation of the arytenoids, but had noticed their recession downwards and backwards when the glottis was opened. The upward movement of the arytenoid cartilage could be seen during life by its producing a pale patch by pressing the blood out of the mucous membrane, the recession of the cartilage being followed by restoration of normal appearance.—Mr. Spitta, in reply, stated that the omission of the membranous portion of the vocal cords from the model was intentional, being due to mechanical difficulties. The articular facets of the arytenoid cartilages had a direction backwards, outwards, and downwards, and therefore they must move in the same direction. Rotation could only take place if the facets were horizontal.

The meeting then adjourned.

CLINICAL SOCIETY OF LONDON.

This Society held its ordinary meeting on Friday, the 22nd inst., the principal business of the evening being the adjourned discussion on the cases of antiseptic surgery brought forward by Mr. Callender and Mr. Pick at the previous meeting. The attendance was, as usual, very good, a large number of surgeons being present in anticipation of an animated debate. The chair was occupied by Mr. Callender in the absence of Sir W. Jenner. Previous to the resumption of the discussion two very interesting cases were brought forward by Mr. Hutchinson, and the patients shown.

Mr. Jonathan Hutchinson showed a case of very curious Tumour or Malformation of the Head. The patient, a child four years of age, was first seen by Mr. Hutchinson at Moorfields, in October, 1871, when six months old, having been brought by its mother on account of a prominence of the eyeballs. The child is the younger of two, and the parents are healthy. When first seen, at the age of six months, there was a nearly hemispherical tumour on the vertex of the head, nearly in the middle line, which was said to have been noticed at birth, but to have been increasing since. The tumour was hard to the feel, and there was a hard ridge extending along the course of the sagittal suture as far as the root of the nose. The anterior fontanelle was not quite closed, but small; and there was considerable proptosis. At the present time the child is in good health, but though four years of age looks only two. She has only just learned to walk, is good-tempered, cheerful, and not passionate. There is no sign of rickets in any part of the body. There is no paralysis, but the right hand is rather weak, and colder than the other. The lower part of the face is natural, but the upper is greatly disfigured by the prominence of the eyeballs and by the tumour. There is a swelling extending from the root of the nose upwards, and out to the angles of the orbits, which are shallow. On the vertex of the head is a swelling about one inch and a half high, and two inches in width, irregularly hemispherical, with a sort of transverse depression across its middle part. The tumour is soft, pseudo-fluctuating; two small plates of bone can be felt in it; and it receives impulse both from the circulation and respiration, but the pulsation communicated is only weak. The skin is not tender over the tumour. Mr. Hutchinson said that he believed the proptosis, which was very considerable (so that at one examination the globe of the eye was completely dislocated), was due to the extreme shallowness of the orbits. In all probability it was not an ordinary case of encephalocele, or of hydrocephalus, but one of defective development of the bones of the skull, the sutures of which had given way with the growth of the brain, and led to its protrusion. At the same time he thought there was possibly also excess of fluid in the ventricles, and that this formed a part of the tumour. In other cases of similar nature a ridge in the line of the sagittal suture had been observed. The pathology of the case was at any rate obscure, and he sought light upon it.

A rather long discussion followed the exhibition of the case, the point considered being the probable nature of the tumour. — Mr. Callender thought from the description that it was probably some form of meningocele with malformation of the bone. He mentioned a case which he had seen under the care of Mr. Stanley, in which the patient lived till the age of twelve. After death the tumour was found to be a soft malignant growth, which had taken nine or ten years in the development externally. Finally, the growth had extended inwards, and had involved the two cerebral hemispheres, reaching the floor of the lateral ventricles. The present case, however, seemed less likely to be of malignant nature, and more probably consisted of the membranes of the brain distended with fluid, owing to defective development of the skull.—Mr. Henry Morris thought that the explanation offered—viz., that the tumour was due to the extrusion of the contents through the opening of the brain-case—was improbable, from the fact that there was such marked protrusion of the eyes; because, if the pressure were only outwards, there was no reason for such protrusion. He mentioned a case of similar character which he saw in an out-patient at Middlesex Hospital eighteen months ago. In this case the patient was a woman, forty-five years old, unmarried, who had received a blow on her head some months before. A soft tumour had subsequently formed, and increased rapidly. When admitted into the hospital she had a soft fluctuating tumour over the parietal region, measuring 5½ in. in diameter, elastic, with slight general pulsation, and some localised pulsation where larger vessels crossed it. Another feature of similarity was the presence of a hard bony ridge at the circumference of the tumour, and the presence also of small bony masses in it. On puncture, only bloody fluid was obtained from the tumour, and no operation was considered advisable. The tumour is now rapidly increasing, but there is no pain. Mr. Couling, of Brighton, thought the case to be one of soft medullary cancer of the diploe, from the similarity to another case in which there was also a tumour of the same kind involving the clavicle. The absence of fungation and the uniform growth might be ascribed to the mechanical conditions which facilitated uniform extension.—Mr. Holmes did not think it clearly proved that the cases mentioned by Mr. Morris were really cases of medullary cancer at all. He referred to a case which was in St. George's Hospital some years ago, under the care of Mr. Cæsar Hawkins, in which, in a man aged sixty, a tumour, occupying a similar situation but further back, had existed for fifteen years. There were no symptoms except occasional epileptiform seizures and attacks of mild delirium. His general health was good. There was a pulsating growth on the top of the head, with here and there more marked pulsation. The patient died of pneumonia, and the growth was found at the post-mortem to be of fibrous nature, pressing on the membranes of the brain and the pericranium. The history of the present case showed that the growth was not really malignant, but came under the head of fungous tumour of the brain, as described by Louis.—Mr. Morris said that the cases were described as of medullary cancer by their authors.

Mr. Hutchinson showed also a case of Ulcer of the Tongue, probably of a cancerous nature; and, if so, of remarkably quiet and slight character. A year and a half ago the patient, who is a man sixty years of age, came with a hard ulcer, the size of a sixpence, on the middle of the tongue; it had hard edges, but was free from warty growth. It was cauterised with nitrate of silver and nitrate of mercury, and the ulcer was greatly improved and nearly healed. This spring another small ulcer broke out at the side of the former, and was again cauterised with temporary good result. There is now a small, slightly indurated, circumscribed ulcer on the middle of the tongue. But the glands under the jaw are now enlarged, and one has softened, with the discharge of much serous fluid, and another beneath the sterno-mastoid is also enlarged. If, as seems probable, the disease is cancerous, Mr. Hutchinson thought it was very quiet and innocent in its appearance, and the case showed the difficulty of diagnosis in some of these cases. Mr.

Hutchinson added, in answer to inquiries, that the family history was good, that the patient's health was good, and that the disease was ascribed to injury with a pipe. No microscopical examination had been possible, and there was no suspicion of syphilis.—Mr. **Henry Lee** thought that the condition and history of the glandular swellings were opposed to the view that the disease was either cancerous or syphilitic.—Mr. **Maunder**, on the other hand, thought that these were in favour of the diagnosis of cancer.—Mr. **Callender** also agreed that it was probably malignant, from the age, characters of the ulcer, and condition of the glands.

The adjourned Discussion on Antiseptic Dressing was then resumed.

Mr. **Pick** briefly narrated the main facts of the case brought forward by himself at the last meeting, and the results obtained; and also mentioned Mr. Callender's cases of treatment with salicylic acid, and the conclusion he drew from his experience with that agent,—all of which we have already fully reported. Mr. Pick said that his great object in bringing forward this case was merely to elicit opinion with regard to antiseptic treatment in general. He himself had great faith in it, but did not consider that it prevented suppuration nor that it hastened union, but that it prevented the *decomposition* of pus, which was what we had to dread. It was especially in cases of excision of joints that its value was discovered; and in his experience as surgeon to the Belgrave Hospital for Children, where, before the introduction of Lister's method, traumatic fever and a foul condition of the pus were of constant occurrence, since its use he had had little or no fever and the pus was always healthy. Moreover he had not had a single case of erysipelas or pyæmia under his care since its employment. He had now a case in St. George's Hospital in which the wound had only been dressed three times since the operation, and this was especially beneficial, as it obviated frequent movement of the wound. He made it a rule never to dress the wound again until the discharge oozed through the dressing. Then, although the pus might be very fetid and offensive in the more superficial layers of the dressing—i.e., where it was in contact with the air,—on reaching the deeper layers it was good and sweet, and the wound healthy-looking. He had treated all his cases of operation with carbolic acid except one, a case of enchondroma in the parotid region; and that patient died of pyæmia.

Mr. **Maunder** had not had the opportunity of hearing Mr. Pick's case read at the last meeting, but he gathered from the reports in the papers that in that case there was traumatic fever, suppuration of the thigh in various directions, and serious general symptoms, ending, in *five months*, with the result of a useful limb. Now, on reflecting on the cases which he had had in his own practice, he thought he had seen like cases treated in the ordinary way with equally good results; and he had collected three such cases, which occurred some years ago, of suppuration in the knee-joint—one a case of ordinary character, which was treated by a free incision, and was soon well; another treated by incision and drainage-tube, which also speedily recovered; in the third case there was very severe injury, and the joint was completely disorganised, suppuration occurring in all directions in the thigh; but the patient was treated with plenty of food and stimulants, and after a stay in the hospital for six months, he left with as good a result as in Mr. Pick's case. (Two of these patients were shown.) He did not say, however, that carbolic acid was of no use; he had used it frequently, and should still continue to do so. But Mr. Lister expects more than Mr. Pick, and would be sorry to stand godfather to Mr. Pick's case; Mr. Lister expects to prevent traumatic fever and the occurrence of suppuration, &c. Mr. Maunder recalled another case of severe injury to the knee-joint, in which another method of treatment was adopted for the reduction of traumatic fever—viz., ligature of the femoral artery. In a case where this was done by Mr. Little, at his suggestion, nine years ago, the arrest of the fever was immediate, and he would be inclined to regard it as equal to Lister's method for the purpose. He guarded himself, however, from the supposition that he was opposed to the antiseptic treatment; for example, he believed that Mr. Pick's care was the cause of the good result, and this was no doubt often the real benefit of the system. He would add that in the case he himself showed the question of amputating the limb was discussed on two occasions.—In reply to Mr. Callender, Mr. Maunder stated that there was an open wound, with laceration and severe traumatic fever, when the ligature was applied.

Dr. **Moxon** inquired whether Mr. Pick made any observation on the presence of bacteria in the pus in the wound?

Mr. **Holmes** remarked that it was evident that the value of antiseptic surgery would never be settled by single cases. It is true that Lister hopes to prevent suppuration, traumatic fever, &c.; but even Lister would not expect it when the patella was cut across and the femur injured, and the patient not seen until some time after the accident. Such cases were not relevant or comparable for the purpose. Cases of open wounds of joints vary greatly in their results under all methods of treatment, so that a comparison of such cases was of no value. What was really wanted was that surgeons who have employed antiseptics of various kinds should give the results of their experience, and of the impressions which they have formed on their value; such impressions would be of far higher value than any individual cases. He himself had used Lister's method for some years, and the more he used it the higher did his opinion of it become. Its chief effect was no doubt the prevention of traumatic fever, and this was especially well seen in the case of the opening of large abscesses, where, if treated by Lister's method, there was in most cases an absence of traumatic fever. But to obtain success it is needful that the wound should be under our control from the first, and not after its exposure to all sorts of external influences of an infectious or irritating nature. He did not believe in Lister's *theory*—i.e., with regard to germs,—as it did not seem to be sufficiently proved by the evidence, but he had no doubt that carbolic acid prevented suppuration. The general principles of his treatment are valuable; probably, however, not the details. The great principle which is of value is the withdrawal of the wound from the influences of the irritation of foreign bodies and of disturbance, and also that the surgeon is obliged to dress it himself. To these facts he attributed the great value of antiseptic surgery, and he was satisfied with the results obtained. He believed that pyæmia occurred in cases so treated, but as to the general prevalence of pyæmia in hospitals he thought a good deal of misconception existed. To show this he had taken the post-mortem records of St. George's Hospital for three years, 1864, 1870, and 1874 respectively, and examined the number of cases of pyæmia. He found that in 1864, out of a total of 360 deaths, there were 11 cases of pyæmia; 8 occurred after various diseases, 1 after childbirth, 1 from diffuse periostitis, and others after accidents, whilst only 3 occurred after operations, 1 of which was for fistula, 1 for hernia, and 1 for excision of the hip-joint. In 1870, 19 cases occurred out of a total of 359 deaths; of these 11 were after accident or disease, and 8 after surgical operations. In 1874, with a total of 241 deaths, only 11 cases occurred, and only 1 of these was after an operation. These details should correct the error as to the undue prevalence of pyæmia in hospitals, showing as they did the relatively small number of cases in a long period of time. A long experience with different methods could alone show the effects of the treatment on pyæmia, as when there were many cases in a ward treated by antiseptics the air became carbolised and to some extent antiseptic. So that, whilst not binding himself to Lister's theory, he had no doubt of the real value of his practice.

Mr. **De Morgan** expressed his belief that a great part of the success of the antiseptic system was due to the extreme care on the part of the surgeon both in the dressing of wounds and the general hygienic measures. This was well illustrated by an inspection of Mr. Callender's cases in St. Bartholomew's Hospital. He considered the antiseptic system of great use—not, however, on account of its purifying the air or excluding air from wounds. With respect to the latter, we know that the free admission of air is not injurious: e. g., in empyema, if there is only a small opening, the accumulation of pus becomes extremely fetid; whereas, if a counter-opening be made and air freely admitted, the discharge becomes sweeter, the air itself not being the cause of the suppuration, but the pent-up air being injurious. Professor Humphry's experience of the treatment of wounds by free exposure and the absence of all restraint had shown how very well wounds may do under this method. In certain cases, however, there was an undoubted gain from antiseptics, such as one published by himself in the first volume of the Society's Transactions, which was a case of caries of the bones entering into the knee-joint, with much suppuration. The joint was freely opened and washed out with chloride of zinc. Healing was rapid and without a bad symptom, and the result good, the patient being able to walk well. This successful result would doubtless not have occurred unless means had been taken to prevent the decomposition of the tissues. He recalled also another case of similar nature, where no fever occurred. In such cases as these the good from antiseptics was undoubted. But in general, if great care be taken to prevent the entry of extraneous bodies and infectious matters, and the general hygienic conditions be attended to, we shall be successful in avoiding all the evils which used to haunt hospital wards. Lister's general rules of treatment might be followed with benefit. Mr. De Morgan expressed his preference for boracic acid over carbolic acid as a dressing. In one case of amputation the use of sulphurous acid was followed by a good result; but the constant care and attention, and the great anxiety on the part of the sister that the case should succeed, were possibly the real causes of success, and not the sulphurous acid.

Mr. Barwell thought that, in speaking of Lister's method and of antiseptics, they were discussing two different things. In Mr. Pick's case, which was really one of compound fracture, all that could be done was to avoid putrefaction, and it did not matter which antiseptic was employed. He thought Mr. Maunder's cases pertinent, as showing that such cases may do well without antiseptics. But in the case of operation wounds, when we make the wound and can control it from the first, Lister's method is very valuable, as we can insure an antiseptic atmosphere around the wound. The lotion employed as a dressing might be varied at will; chloride of zinc being very valuable in some cases, or dressing with carbolised collodion; in one of the latter no trace of suppuration had occurred. Results were obtained by Lister's method which could not be otherwise got, but in his opinion Mr. Lister had mixed up with his method many details which were very repulsive to surgeons, and had thus done himself and his method an injury.

Mr. Christopher Heath narrated his experience of a visit to Professor Lister's wards in Edinburgh before the meeting of the British Medical Association. He did not, he said, go to see the show cases, but beforehand, and was surprised with the results which he saw. For example, he had seen a case of excision of the femur, where there was a slit for ten inches in length along the thigh, and when uncovered under the spray, he saw the clot undergoing organisation, and, still later, the same case was shown at the meeting of the Association with the wound healed. Many other cases of equally surprising character were shown to him. Mr. Lister himself showed him the details of his method, and insisted on all the minutiæ, regarding them as of great importance. If any case went wrong, there was always some slight mishap or omission in these details, to which the failure was ascribed. This being the case, he was surprised that Mr. Holmes should say that he had taken up the method and yet did not follow the minutiæ. If so, which of them is it that he omits? Mr. Heath said that the method was repellent to him, especially the operating with a cloud of spray on one's hands, and often in one's eyes, and he had almost resolved each time he employed it not to do it again. In cases of ordinary compound fracture, he did not find that the method always gave better results than the ordinary treatment; in two cases now under his care, the one treated in the usual way was going on quite as well as the other. He had seen elevation of temperature after operation under the antiseptic treatment. Lastly, he inquired why, if Mr. Maunder approved of ligature of the femoral to check traumatic fever, he did not employ it in either of the cases he had narrated.

Mr. Maunder explained that the reason why he had not ligatured the femoral was that in one case, where he had advised it shortly before, the result was merely ephemeral.

Mr. Thomas Smith protested against the idea of discussing Lister's method whilst omitting the details on which he insisted so strongly. We should accept his method *in toto* or reject it altogether. Lister objects to carrying out his method in such a way, as he says, as to court failure. He instanced a thing often done in the middle of an operation: the operator takes up a pair of forceps, and dips them in carbolised lotion, and then uses them in the wound; whereas they should be soaked for half an hour. This, Prof. Lister says, is to court failure. This may seem absurd to us, but we ought to follow all his details, or not to say that his method is a failure. At present Mr. Smith did not see that any evidence had been brought forward to justify the statements for or against it.

Mr. Barwell, in reply to Mr. Smith's strictures, explained that all he wished was to simplify Lister's method.

Mr. Croft said that he had visited Lister's wards in Glasgow some years ago, and was so impressed with the improvement in the wards that he had begun the treatment at St. Thomas's on his return. He could say much in favour of Lister's method from his own experience, but at present would only suggest the hope that hospital surgeons would not look at it only from the point of view of the patient operated on, but would also consider the other patients in the same ward. The condition of the atmosphere in the ward was of great importance to the other patients, and had much to do with the prevalence of pyæmia in the wards.

At this point, the time having expired, the discussion was adjourned to the next meeting, when it was understood that Mr. Holmes would bring forward a paper on the same subject.

MEDICAL SOCIETY OF LONDON.

Some interesting cases were brought forward at a clinical meeting held on the 25th inst., Dr. Routh, President, in the chair.

The proceedings opened by Dr. Thorowgood reading notes of a case of Acute Pneumonia in a man aged forty-five, who had been an inmate of the West London Hospital. The patient had all the signs of pneumonia in the right base, but about the seventh day the expectoration, from being rusty, became black and most offensive; between the tenth and fourteenth day the condition was critical, the skin being clammy, the cough violent and paroxysmal, the temperature 102·6°, and the breath so fetid that it could be smelt all over a ward fifty feet long. Ammonia and bark in very full doses, Dover's powder at night, and six ounces of brandy and four ounces of wine in the twenty-four hours, were administered, and under this treatment the patient recovered and returned to work as a labourer, though slight cough and expectoration, together with some dulness at the right base, still remained. Dr. Thorowgood, after alluding to the rarity of pulmonary gangrene as a termination of acute pneumonia, said he considered the case one of limited slough of a portion of lung-tissue, due probably to the plugging of some of the vessels by the pneumonic exudation. He remarked that a very small slough or gangrene may cause great fetor of the breath, and drew attention to the improvement of the patient under liberal stimulation. In conclusion, he stated that previous to the attack the man had been in good health, with the exception of a winter cough; there was no albuminuria, and the patient was of sound mind and temperate habits.—In the discussion which followed, Dr. Theodore Williams said he had seen patients die of gangrene of the lung, and in the cases which recovered, vomicæ remained, followed sometimes by well-marked phthisis. He thought the disease was always brought about by some great trial of the strength and constitution, and with regard to the sputa he drew attention to its peculiar smell when kept, called the "cowslip odour" by Dr. C. J. B. Williams. The speaker suggested carbolic acid to check the fetor and sedatives for the excessive cough, and concluded by remarking that the disease is not so uncommon in England as it is said to be on the Continent.—Dr. Rogers related a very severe case of this kind in which very beneficial results had followed free stimulation, the patient having previously been kept too low.—Dr. Farquharson suggested the name of "bronchorrhœa" for these cases, as applied by Professor Laycock and Dr. Gamgee, of Edinburgh.—Mr. Myers related the case of a soldier who had come under his care presenting the same features as Dr. Thorowgood's, though the patient had a very phthisical history, and in which a stimulating treatment had produced great improvement.—The President divided this class of cases into four sections:—1st. Those of phthisical character.

2nd. Those of simple pneumonia, in which the fetor was intense. 3rd. Bronchorrhœa, with dilatation of the bronchi. 4th. Those where the patient had been exposed to bad drainage.—After Dr. Thorowgood had said a few words in reply,

Mr. Hutchinson related the case of a patient aged sixty, suffering from dyspepsia and indigestion, together with the expectoration of arterial and frothy blood to the amount of five or six ounces daily, there being no pulmonary symptoms whatever beyond a slight cough at the time of expectoration. The medical men were puzzled till it was discovered that the blood welled up through a small ulcer by the canine tooth. The patient had worn a plate with artificial teeth some time without changing, which had become in an intense state of fetor; rapid recovery followed treatment of the ulcer and removal of the plate.

Mr. Richard Davy then exhibited a man with enormous Hypertrophy of the Buttock Tissues, which had existed for thirteen years. The patient, who was in excellent health, measured 32½ inches round the waist, and 54 inches round the buttocks. Mr. Davy thought the flabby tumour was probably an exaggeration of connective tissue and fat, and disapproved of any operative interference, merely suggesting a shoulder-belt as a support to obviate the great inconvenience.—Mr. Maunder did not consider the tumour fatty, and drew attention to a similar case in the Transactions of the Pathological Society brought forward by Mr. George Pollock, and called Fibroid Molluscum.—Dr. Brunton had seen like appearances in the whole of the body of a Scotch giant, there being no increase of fat, but enlargement of the fibrous tissue.

Dr. Dowse next recounted the case of a man who had died from Syncope after Violent Hæmorrhage. The patient, a costermonger, with no history of syphilis, was emaciated when first seen, the heart-sounds being healthy, though the dyspnœa was urgent, and no aneurism could be detected. After death the arch of the aorta was found to be in a sacculated condition, with acute inflammatory changes in the inner coats, the vessel being adherent to the trachea, into which a small ulcer opened. The preparation was shown.—Dr. Symes Thompson thought it strange no tracheal breathing was audible between the scapulæ.—Dr. Theodore Williams asked if there existed any difficulty in swallowing, or any signs of pressure on the recurrent laryngeals.—Dr. Dowse, in reply, said there was nothing but pain between the shoulders.

Mr. Maunder read an extract from a letter written by a gentleman from New Zealand whose elbow-joint of the right arm he had excised six years ago, in which the patient says he has won the champion billiard cue, and taken second honours in quoits, proving the efficacy of Mr. Maunder's method of incision, by which active extension of the triceps muscle is secured, and examples of which had been exhibited to the Society five years ago.—Mr. Davy and Mr. Adams made some congratulatory remarks.

Dr. Henry Smith showed a Testicle which he had removed for strumous disease, both as a good example of the disease and to illustrate his plan of performing castration without tying the cord, but by seizing it with the ordinary hæmorrhoidal clamp, and applying the actual cautery; this method he had carried out in three or four cases, and all with perfect success with regard to the stopping of the hæmorrhage. He supported this practice, though it was going back to old surgery, and thought it lessened the liability to blood-poisoning.—Mr. Royes Bell corroborated Mr. Smith's statements.—Dr. Drysdale wished to know the condition of the epididymis in this case, and drew attention to the difference between a syphilitic and a strumous testicle.—Mr. Myers thought the cautery advantageous in hospital practice, but in the country he suggested it involved a risk of secondary hæmorrhage with no one at hand to control it. He advocated the use of the catgut ligature, and considered the temperature of the cautery when used as a most important point.—Mr. Davy had used the catgut ligature to the spermatic artery in a case of castration, and drew attention to the castration of dogs in which the testicle is merely wrenched out.—Dr. Cook related an operation by the late Mr. Partridge, in which a testicle was removed from the perineum and nothing used.—Dr. Farquharson mentioned the castration of lambs as being performed merely with the teeth of the operator.—Mr. Smith briefly replied, and the meeting adjourned.

Reviews and Notices of Books.

A Practical Treatise on Diseases of the Eye. By Robert Brudenell Carter, F.R.C.S.; Ophthalmic Surgeon to St. George's Hospital; Surgeon to the Royal South London Ophthalmic Hospital; Consulting Surgeon to the Gloucestershire Eye Institution; Hunterian Professor of Surgery and Pathology to the Royal College of Surgeons of England. London: Macmillan and Co.

It would be difficult for Mr. Carter to write an uninstructive book, and impossible for him to write an uninteresting one. Even on subjects with which he is not bound to be familiar he can discourse with a rare degree of clearness and effect. Our readers therefore will not be surprised to learn that a work by him on Diseases of the Eye makes a very valuable addition to ophthalmic literature. A specialist like Mr. Carter may have two objects in view in writing a book on his own specialty. He may propose to himself to write for the benefit of general practitioners, discovering to them the secrets and the principal points of his own branch of practice; or he may write as a specialist for specialists, subjecting his own views and practice to their criticism. Our perusal of this book leads us to the conclusion that Mr. Carter had both these objects in view, but especially the former. He is characteristically original in suggestion. His book abounds in lively and smart criticism of the work and views of other specialists of eminence. It is also full of details of personal practice which, in turn, will afford ample material for criticism. But it is to be gathered from the preface, and from the book generally, that Mr. Carter has written it for the use of the profession at large. "My aim," he says, "in the composition of the following pages has been to place before the profession, in a concise and readable form, a general view of the present state of knowledge with regard to the nature and treatment of the more important diseases of the eye." Mr. Carter is no narrow specialist. He would like to see general practitioners skilful in detecting and treating the gravest forms of eye disease. Some of the happiest operations for cataract which we have seen have been performed, in the old style, by general practitioners. Mr. Carter would have them equal to every emergency, including that which requires the prompt performance of iridectomy. Such a feeling is not more liberal on the part of a specialist than it is just and encouraging to general practitioners. The author remarks:

> "The operative surgery of the eye is an art which demands, from any who would either understand or practise it, a careful and twofold study: first, a study of the mechanical arts that are to be accomplished; next, the training of the hands to the uses to which they are to be put. Such study, moreover, should not be considered superfluous by any surgical practitioner, however little he may design to be an ophthalmic specialist; for as there are conditions in which the prompt performance of iridectomy is at least as essential to the preservation of vision as the prompt performance of herniotomy, or the prompt deligation of an artery, can ever be to the preservation of life, so no one should think himself entirely fitted to enter upon the responsibilities of surgical practice until he has prepared himself for the discharge of either duty in an efficient and creditable manner."

We have long held that far more good specialism is realisable in general practice than has yet been attained. If specialists would take a little more pains to elucidate the principles and details of their practice, and so to facilitate the learning of them by general practitioners, we should have that best of all results, the multiplication of the special aptitudes of general practitioners. Whatever may be thought of specialism, there can be but one opinion that the more special knowledge every practitioner has the better practitioner will he be. No one will read Mr. Carter's book without having both his special and general knowledge increased, and without feeling more intelligently convinced of the need of more specialism in general practice, and more general knowledge in special practice.

The ophthalmic specialty has been wonderfully developed of late years. Practitioners who know no more of eye diseases than was to be learned in the course even of their special study twenty years ago will be amazed at the changes which have taken place in knowledge, in doctrine, and in practice. The new applications of iridectomy in cataract operations, in glaucoma, in keratitis, &c., the use of the ophthalmoscope, the transplantation of conjunctiva, the elucidation of diseases of refraction, the study of the remote or constitutional significance of certain morbid conditions of either the deeper or more superficial parts of the eye, are a few of the points which mark the recent strides of this specialty, which has commanded the respect alike of the public and the profession, both for the scientific spirit in which it has been studied and the brilliant results which it has achieved.

It is no light task to undertake to present to the profession the state of knowledge and practice in this department. But Mr. Carter has undertaken it; and we think the profession will consider that he has acquitted himself well. The book is not a mere text-book describing in a routine way the recognised views; it is throughout practical and personal, containing but slight reference to modes of practice beyond the experience of the author.

The general plan of the book is as follows:—The first chapter treats of the Anatomy and Physiology of the Eye; the second of the Examination of the Eye; the third of the Ophthalmoscope and its application; the fourth of the Principles of Ophthalmic Therapeutics; the fifth of the Principles of Ophthalmic Surgery; the sixth of Diseases of the Lids and Lachrymal Apparatus; the seventh of Diseases of the Conjunctiva; the eighth of Diseases of the Cornea; the ninth of Diseases of the Iris, including Irido-choroiditis and Sympathetic Ophthalmia; the tenth of Cataract; the eleventh of Glaucoma; the twelfth of Diseases of the Fundus Oculi; the thirteenth of Injuries of the Eye; the fourteenth of Squint and Affections of the Ocular Muscles; and the fifteenth of the Uses and Selection of Spectacles. Under one or other of these heads, Mr. Carter manages to express an opinion and give advice on almost every practical point in ophthalmic pathology and in ophthalmic therapeutics, whether medical or surgical. Some of these opinions are new and independent, but they are always supported by arguments based on physiological and clinical facts. It would be difficult to analyse the various chapters and appraise their exact value, the more so as they are all full of suggestions which can only be tested clinically. But we must notice some of them.

One of the best chapters in the book is the fourth, which treats of the Principles of Ophthalmic Therapeutics. The importance which is attached by the author to nerve lesions in the production of grave diseases of the eye, and, correspondingly, to the action of bromide of potassium; the suggestion that iodide of potassium and mercury have applications in other than syphilitic cases; that mercury has some special influence over inflammatory lesions in the region of the fifth pair; that pain must have special and considerate treatment; that atropine is much too inadequately used—are opinions of the highest practical importance. The chapter which treats of Conjunctivitis includes an excellent account of purulent ophthalmia as it affects schools and other institutions where numbers congregate under insanitary conditions. Admirable, too, is the chapter on Diseases of the Cornea, with this practical keynote, "all forms of inflammation of the cornea, or, as it is conveniently called, keratitis, are broadly distinguishable from inflammation of the conjunctiva by this marked character, that they will not bear astringent or irritating applications." A noticeable feature of this chapter is the frequency with which the author commends iridectomy in urgent or intractable or recurrent forms of corneitis. In it mention is made of a new way of performing iridectomy with M. de Wecker's scissors, concerning which Mr. Carter has given a still later account at the Clinical Society, and which there is reason to believe will turn out to be a very satisfactory operation. He claims for it the advantage that the operator is more able to control the size of the gap in the iris, and less likely to injure the lens, than in other methods. We will only quote one remark in the chapter on Iritis. Mr. Carter says—and he is a most orthodox receiver of Ricord's views of the use of mercury in syphilis,—"The influence exerted upon iritis by mercury, and the necessity for administering it in certain cases, seem to me to be essentially independent of the syphilitic or non-syphilitic character of the affection." Resistance to atropine is with him the one sufficient proof that mercury is needed.

Possibly the chapter that will be read with most interest by specialists is that on Cataract. Mr. Carter estimates that 20 per cent. of the old cataract operations went wrong. The introduction of iridectomy and the careful pathological observations which led up to it are well stated. The chapter is full of valuable criticism and discrimination, not unmixed with a dash of satire on some recent operations, which makes the chapter more pleasant reading to everybody, except, perhaps, the authors of the operations condemned. Passing over the important chapters on Iritis, Irido-choroiditis, and Sympathetic Ophthalmia, and a most lucid one on the Use of Spectacles, we have only space left to notice the chapter on Diseases of the Fundus, and we do this principally to mention Mr. Carter's dissent from the views held by Dr. Hughlings Jackson and others on the significance of "choked discs." In this matter, as in so many others, the eye is an object of interest to the general physician, and Mr. Carter's knowledge of general medicine, combined with his special knowledge of the eye, makes his words on the value of choked discs as evidence of coarse intra-cranial disease interesting.

Here we must leave Mr. Carter's book. We will not claim for it faultlessness. Some of the opinions expressed in it may be discredited by the "test of time," and may be shown to have been formed too easily; but the book will remain one useful alike to the general and the special practitioner. Not the least valuable result which we expect from it is that it will to some considerable extent despecialise this brilliant department of medicine.

CORONERS' FEES.—At a meeting of the Middlesex magistrates last week the report of the Committee of Accounts and General Purposes was presented, which recommended that the following coroners' accounts, after having been verified on oath in open court, be paid:—Mr. Humphreys, 262 inquests, £415 8*s.*; Dr. Hardwicke, 185 inquests, £379 1*s.* 10*d.*; Dr. Diplock, 95 inquests, £176 7*s.*; Mr. Payne, 11 inquests, £18 18*s.*; Mr. Bedford, £99 15*s.* 6*d.* Captain Morley, in moving that the coroners' accounts be paid, said it was most gratifying to him to find that, as compared with the corresponding six weeks of last year, although there had been 42 more inquests held, the cost had been £103 less, being a saving of nearly £1000 per annum. After the remarks which he had felt it to be his duty to make in reference to the coroners' accounts, it must be pleasing to the Court to learn that more satisfactory results had been arrived at. We hope the gallant captain is now satisfied.

THE LANCET.

LONDON: SATURDAY, OCTOBER 30, 1875.

It was not difficult to forecast the future sanitary policy of the Local Government Board from the 286th section of the Public Health Act, 1872. The section was, indeed, at the same time, a confession of failure and the promulgation of a policy. In coming so early to Parliament for powers to enforce such an arrangement of districts and their medical officers as would admit of some reasonable relationship between areas and the duties to be performed therein, the Board proved how completely it had failed to secure the confidence of the new sanitary authorities. The straits must indeed have been desperate which, after so brief an experience, could have compelled the Board to stultify its vaunted "educational policy" and policy of "local health self-government" by asking means to regulate both the "education" and the "self-government" compulsorily. We apprehend that Mr. Sclater-Booth had no choice in the matter if he indulged in any hope of struggling successfully against the legacy of muddle left by his predecessor, and Mr. Stansfeld's support of the compulsory clause proved how urgent its need must be. The clause foreshadowed a defined policy of the Board as to appointments of medical officers of health. It indicated an approval of districts large enough to remunerate competent men for giving up their whole time to the duties of medical officers of health, the Poor-law medical officers, when necessary, acting as assistant medical officers. The initiation of a policy of this kind would show that the Board had profited somewhat by experience; and, backed by the power conferred upon him by the Public Health Act of 1875, it would go hard if Mr. Sclater-Booth did not rectify to a greater or less extent the perverse blunders of his predecessor in this matter. To this end, it would clearly not be enough, after the manner of Mr. Stansfeld, to seek the union of districts solely with reference to incidence of expense, the fitness of the area for the particular purpose for which they were united being disregarded. Some sort of reasonable relation between areas and duties it might now be expected would be insisted upon, the area of the united district being regulated by the possibility of due performance of the duties for which it was designed, as well as by considerations of incidence of cost. Nothing of the kind, however, we regret to state, seems to be contemplated. The conception of Clause 286 of the Act would appear to be empirical, and it is to be carried out empirically. That is to say, the general inspectors of the Board are to be entrusted with the interpretation of the policy of the clause to sanitary authorities, each, as heretofore, advising according to his own peculiar notion; and thus another phase of the Board's educational policy of the blind leading the blind is to be exhibited. Mr. Stansfeld blundered in endeavouring to initiate novel arrangements, demanding skilled knowledge for their successful completion by agents entirely unversed in their nature, failing to distinguish what could be compassed by common intelligence, and what could alone be carried out by means of technical information. Mr. Sclater-Booth, although he has had to ask for a legislative knife to cut the tangled knot tied by his predecessor, is about to perpetrate the same blunder in a hardly less mischievous fashion. Although the Board has been compelled unwillingly to adopt a policy urged upon it ever since its establishment, it has determined to make the ultimate object of that policy — namely, the establishment of efficient medical officers of health—subsidiary to other considerations. In the initiation of the new policy as of the old, all competent knowledge of the duties and functions of a medical officer of health and their practicability of performance is being studiously excluded, and the general inspectors are being left to talk at large utter nonsense regarding them to sanitary authorities. A policy therefore, capable of being worked to infinitely good purpose, is to be rendered largely a sham in order to maintain the traditional Poor-law routine of Gwydyr House. Mr. Stansfeld reproached the medical profession for contending that, in this matter, the means should be designed with direct reference to the end they were intended to promote. Mr. Sclater-Booth, it is to be feared—and we regret to say it,—has drifted into the same tone of thought.

Indeed, so far as the projects of the several inspectors of the Board have as yet become known, it would appear (as we have before had occasion to point out) that it contemplates the appointment for large districts, not of medical officers of health in any sense of the term yet known, but of district medical inspectors, the intimate duties of a medical officer of health being done by the Poor-law medical officers. While the whole tendency of experience has been to show that the duties of a medical officer of health will be augmented in value in proportion as they can be carried out in detail, by this proposition the converse is assumed, and the efficiency of the office weakened at the very point where it needs strengthening. It cannot be urged that it would have been impossible to reconcile the question of cost with the view of a medical officer of health's duties supported by experience, for the question has clearly never been entertained. It was one which might well have brought into play the highest qualities of a Minister to solve, but it has been treated as the merest matter of circumlocutional routine peculiar to a particular Government department. In other words, the sanitary administration of the country is treated as a branch of Poor-law administration.

Assuming that the Local Government Board is successful in carrying out its new policy, it is not difficult to understand the anomalous position in which the newly appointed medical officers will be placed. They will have the same relationship to their Sanitary Authorities, on the one hand, and to the Local Government Board, on the other, which is held by the Poor-law officers with relation to the Board of Guardians and to the Central Board. The position of the Poor-law medical officer in these respects has probably given rise to more heart-burnings in the profession than any other cause. How a like position is to be maintained under the grave responsibilities of a medical officer of health, except by the Central Board setting on his shoulders, after the simple but effective fashion of the Old Man of the Sea, is to us incomprehensible. To the kind of relationship maintained by the Poor-law Board between itself and the Poor-law medical staff, through its ordinary inspectors, was due the greater portion of the scandals which have disgraced the sanitary history of workhouses in recent years in this country. The same kind of relationship is to be maintained between the Local Government Board and the medical officers of health. Already the anomalous nature of this relationship is being experienced. The time is rapidly approaching when the temporary periods of appointment of the medical officers of health for united districts will terminate; and much uneasiness is felt by the holders as to the course which may be pursued by the Local Government Board in the future with regard to these districts. A meeting of medical officers of united districts took place in London last week, and from it a deputation was sent to Gwydyr House, and had there an interview with Mr. SCLATER-BOOTH. The members were received with much courtesy, and made the important discovery that they were balls in a very pretty three-cornered game, in which the bats were held by the Local Government Board, the general inspectors of the Board, and the Local Authority. We need not point the moral of the discovery, and we shall wait with interest to see what further course the medical officers of united districts will take.

◆

A SECOND very valuable and important series of researches on the Lymphatics, undertaken for the Medical Department of the Privy Council, has just been published by Dr. KLEIN, the assistant-professor at the laboratory of the Brown Institution. The present volume deals with the Lymphatics of the Lung, both in their normal and in their pathological conditions; and Dr. KLEIN informs us in the preface that the research was originally intended to ascertain the relation of the lymphatic system of the lung to the process of tuberculosis. It was soon ascertained, however, that the incomplete state of our knowledge of the lymphatics of the lung rendered it imperative to subject them to a careful scrutiny with a view of discovering their minute distribution. The result of the investigation has proved of extreme value in elucidating the process of artificial tuberculosis in guinea-pigs, and the process of acute miliary tuberculosis in man, which are fully discussed in the second section of the volume.

Dr. KLEIN commences his account of the normal condition of the pulmonary lymphatics by a minute description of the cells investing both the costal and the pulmonary pleura; in the course of which he shows that, whilst those of the costal pleura are ordinary pavement epithelium, those of the pulmonary pleura present considerable differences, according to whether they are examined when the lung is in a contracted or in an expanded state. In the expanded condition of the lungs the cells forming the endothelium covering it are flattened, rather thicker at their centres than at the periphery, with pale and transparent cell-substance, and discoid excentric nucleus. When stained with nitrate of silver the lines of junction of the cells are marked by fine, dark striæ, enclosing polyhedric areas. In the contracted condition, on the other hand, the cells are no longer flattened plates, but are polyhedral or even columnar, with rounded apices; their contents are distinctly granular, and the nucleus has assumed the form of a slightly flattened spheroid. The change in the form of the cells causes a different appearance to be presented when the superficial and the deeper parts are respectively brought into focus. In the former case the cells appear as spherical bodies, separated from each other by broad furrows; in the latter case they appear like a continuous mosaic of cells, separated by thin intercellular lines. Dr. KLEIN points out that the differences between the endothelial cells of the collapsed lung and those of the costal pleura are very similar to the differences observed by WALDEYER between the cells covering the upper part of the ovary and those lining the peritoneum generally.

He next considers the matrix of the pulmonary pleura, which he describes as composed of very delicate bundles of connective-tissue fibres, with a few fine elastic fibres crossing each other in various directions, and leaving spaces between them, each of which contains a flattened nucleated connective-tissue corpuscle. These spaces, with the contained corpuscles, intercommunicate freely, and constitute the so-called lymph canalicular system. In guinea-pigs there are in addition slender bundles of unstriped muscle-fibres, arranged so as to form a network with long rhombic meshes. The position and arrangement of these fibres are minutely described, and it is shown that the lymphatics are in close relation with them; and that since the meshes enlarge and contract with the movements of the lung in inspiration and expiration, they must exert a pumping action, exercising an important influence in promoting absorption from the pleural cavity. But the question naturally arises, Is there any direct communication between the cavity of the pleura and the lymph canalicular system? And Dr. KLEIN answers this in his third chapter by showing that there are stomata surrounded by germinating epithelium on the surface of the pulmonary pleura, which are connected by short vertical tubes communicating with the lymphatic lacunæ of the muscular coat, which again communicate with the subpleural lymphatics, the distribution of which he carefully describes. In the mucous membrane of the bronchi the lymphatics open on the surface in a different way. Here there are indeed no stomata nor vertical tubes, but Dr. KLEIN has discovered what he terms a pseudo-stomatous tissue, consisting of isolated connective-tissue cells, differing in their shape, their refractive power, the character of their nucleus, and their mode of staining—in short, in all their morphological characters—from the adjoining epithelial cells. These cells occupy spaces which, like the true stomata, form communications between the free surface and the submucous lymphatics, but, being filled with the cells, are impervious, unless the tissue is expanded or distended. Further investigation showed that there is a system of perivascular lymphatics around the bloodvessels of the alveoli.

It thus appears that the radicles of the lymphatics of the lung are distributed over three different parts—the walls of the alveoli, the walls of the bronchi, and the pulmonary pleura. The first system is represented by irregular lacunæ and anastomosing vessels, being the spaces for the branched connective-tissue corpuscles. Some of the vessels of this system, appearing on the surface, form the *subpleural lymphatics;* whilst others accompany the branches of the pulmonary artery and vein, and constitute the *perivascular lymphatics;* the larger vessels running towards the root of the lung. The second system is represented by irregular lacunæ and anastomosing canals in the mucosa, both of which are lined by connective-tissue corpuscles; the lymphatic vessels originating in these have a special endothelial wall, and form a network of *peribronchial lymphatics,* in connexion with which are some lymphatic follicles, and discharge themselves into the same efferent vessels as the perivascular lymphatics of the alveoli. The third system is that of the pulmonary pleura, which, as already stated, is supplemented in the guinea-pig by a system of *intermuscular lymph spaces.* The subpleural lymphatic vessels stand in a direct open communication with the pleural cavity by means of *stomata;* whilst the radicles of the perivascular and peribronchial lymphatics stand in an indirect communication with the alveolar cavities or the surface of the bronchial mucous membrane, respectively, by means of *pseudo-stomata.*

We shall proceed on another occasion to show the bearings of these anatomical facts upon the pathology of the lung, a subject of the utmost interest in relation to the most important disease of this country—tuberculosis.

◆

A few weeks ago, in a short article, we ventured to question the propriety of medical men selling their services on terms calculated to give a very poor idea of their own sense of the value of those services. We instanced the case of a gentleman in the provinces who issued a handbill to the effect that the poor might have his advice and medicine for threepence, and might be visited at home and supplied with medicine for sixpence. These terms seemed to us not to represent the value of medicines, much less of medical services or the dignity of the profession. Our remarks have called forth several letters in defence of what we have called, in no offensive spirit, cheap doctors. In our original remarks we said that the system we criticised was not unknown in London. Our correspondence shows that it is extensively practised. One of the gentlemen who practises it, signing himself "S.," in a very temperate and well-written letter, puts its advantages very well indeed. He describes a kind of practice which seems to have fascinated several other correspondents. He is not troubled as other practitioners are. He lies all night in his bed. He attends no midwifery. He keeps no books. He makes no bad debts. He has no bills to make out. Before he began what he euphemistically calls the dispensary system applied to private practice, his receipts were £5 a week. Since he opened a dispensary his receipts have become £16 a week. His health is better. His circumstances are better. He has more leisure; and he maintains that he does not neglect his patients or fail in giving them the most expensive medicines which their case requires, including quinine and opium and iodide of potassium. He knows several gentlemen with dispensaries who use quinine largely. These statements are too circumstantial, too impressive, and altogether too important to be lightly dismissed.

In answer to the request of several correspondents, "S." gave in last week's Lancet details of the way in which he works his private dispensary. He charges one shilling for seven days' attendance, and three shillings when the patient requires to be visited at home. Prepayment is insisted on, and dates are accurately kept on a card. Such is the system out of which our correspondent receives £16 a week, or £832 a year, with no other expenses than those for drugs and an assistant. If report may be trusted, it is possible to make three times this sum out of the system.

We have great respect for all honest and honourable attempts to solve the problem of attending the poor as private patients. It is one of the most difficult of practical problems. They must be attended. The need for medical attendance is an urgency. It is one which must be supplied either gratuitously or at a moderate charge. Such is the peculiar pitiableness of the case of the sick poor that medical men instinctively attend to their calls. Nobody expects a baker to supply loaves for nothing even to starving people. But somehow or other doctors are expected to supply attendance and medicines to sick people, leaving the question of payment for settlement at a future time, when neither the sentiment of gratitude nor of justice may be strong enough to secure him being recompensed. It is one of the most discreditable things that can be noted in the morals of society to see how people who have been helped in trouble by a doctor—had a peritonitis cured, or a typhoid conducted to a safe issue, or an arm presentation rectified—will sneakingly evade their benefactor and live out the life he has saved for them without an attempt to pay him. As regards the working classes, we see no hope at present of getting them to pay adequately for medical attendance on them and their families. They will have to be much further advanced in education, including morals, before this is possible. The choice at present lies between the provident system and some ready cheap system such as that which "S." practises. But the question which we have to discuss at present is, Is the system of "S." satisfactory?—or rather, without pretending that it is satisfactory,—is it to be excused and borne with as a stepping-stone to a better system? We may fairly content ourselves with having published "S.'s" statement of the arguments for, and the advantages of, the system. Let us see what objections can be brought against it.

First, with all respect to "S.," we must question the possibility of supplying proper medicines on such terms. Supposing the patient to come only three times for his shilling and require a bottle of medicine each time, we cannot see how it is to be supplied and well dispensed for such a sum. Respectable druggists, at any rate, do not dispense medicines to medical men on such terms. They charge medical men sixpence to eightpence for a mixture. Some highly methodical and conscientious man, with an assistant to match, may supply something worthy of the name of medicine for this sum, but in the hands of men who are not methodical and not conscientious such a system must supply the patient with inferior medicines. People cannot get decent beer on such terms, and they will not have their respect for medicine raised by them. What shall we say of the possibility of examining cases properly under such a system? Let us suppose that the sixteen pounds a week represent over two hundred shilling cases and thirty-five three-shilling cases. The most of the latter will have to be seen and ought to be prescribed for from day to day—some twice a day. Let us suppose them seen, on an average, six times in the week. The shilling cases we will suppose to be seen three times for a shilling. This will give a daily round of thirty visits a day at patients' houses, and a hundred patients to be seen at the doctor's house. We submit that that amount of work cannot be properly done by one man, that it is not possible to do justice to the cases, and that the remuneration is altogether inadequate. Next, let it be observed that this system does not profess to deal with the obstetric necessities of families. Midwifery is not attended, and obviously could not be.

But we shall be met with the argument that it pays. But does it pay? We have pretty well shown that, if proper medicines are supplied and proper attention given to cases, the system cannot pay the particular medical man who works it; but what of the neighbouring medical men whose better patients are lured by this cheap system? "S." tells us nothing of the demoralising effect on the patients. It will not do to reply that the medical charities are abused. They are, at any rate, open to public inspection. Not so with the private dispensaries. We are not told of any attempt to discriminate patients. And we cannot doubt that the hundreds who go to swell this system and make it pay comprise scores of people who could pay sums to their own medical men more proportionate to the value of medicine and medical services. It may pay one medical man, but it tends to rob and lower the profession. Before the system can be countenanced by those who wish to uphold the dignity of the profession, three points should be attended to: the sums charged should be doubled; care should be taken to exclude improper persons; and the system should include an arrangement by which persons might be enticed to ensure medical attendance in sickness by a "provident" arrangement.

Annotations.

"Ne quid nimis."

THE METROPOLITAN SCARLET FEVER EPIDEMIC.

October is almost invariably the most fatal month for epidemic scarlet fever. During the thirty-two years 1840–71 the average weekly number of deaths from scarlet fever in London was 49, whereas the weekly average was 76 during October—more than double the average during March, April, and May, when the disease is least fatal. The present October forms an exception to the general rule, as the fatal cases of scarlet faver in London have been steadily increasing during recent weeks. Scarlet fever caused 359 deaths in London during the first three weeks of October, against 330 in the same period of last year. In the corresponding three weeks of 1869 and 1870 the recorded deaths from scarlet fever were 673 and 582 respectively. The present epidemic therefore, which may be said to have commenced in July, 1874, has hitherto been far less severe in London than was the epidemic of 1868–9–70, and judging by the experience of past epidemics there is every reason to anticipate that after this month the number of fatal cases will begin to decline. Although small consolation is to be derived from the fact, it is not without interest to learn from the Registrar-General's weekly returns that, although scarlet fever is so fatally prevalent in London, the death-rate from the disease last week exceeded that in the metropolis in Bristol, Nottingham, Leicester, Salford, and Bradford, due allowance being made for the difference of population.

The Metropolitan Asylums Board, at their last meeting, took into consideration the excessive demand for hospital accommodation caused by the increasing prevalence of scarlet fever among the poorer classes of the metropolis. It was reported that the Homerton Fever Hospital contained 168, and the Stockwell Fever Hospital 85, scarlet fever patients. In consequence of the Homerton Hospital being overcrowded, it was decided to reopen the Small-pox Hospital at Homerton (which had been closed for months, as there was no demand for accommodation for small-pox), and to use it as a scarlet fever hospital. Since the beginning of July last the weekly number of scarlet fever patients in the two Asylums Board fever hospitals has steadily increased from 151 to 253 on the 23rd inst., and has averaged 184 in the sixteen weeks, of which 113 were accommodated at Homerton and 71 at Stockwell. The value of the Asylums Board Fever Hospital in the repression of typhus and enteric fever appears to be beyond question, and there is every reason to believe that this increase of hospital accommodation for scarlet fever will be infinitely useful in securing the isolation of the sufferers, and, in the absence of evidence to the contrary, it may be hoped that the hospital treatment reduces the proportion of mortality in the cases. On this point statistics would, however, be valuable, for the advisability of treating scarlet fever in large hospitals is not admitted on all hands.

THE ADMINISTRATIVE AMENITIES OF THE LOCAL GOVERNMENT BOARD.

We received, some few days ago, certain copies of provincial journals, which told at great length and with painful perspicuity of the sayings and doings of the Local Government Board relative to a new workhouse about to be erected at Sheffield. It appears that, as usual, the local authorities have been playing at how not to do it in the matter for some months, but were at last persuaded or compelled to take the sense of the Gwydyr House authorities on the subject. Certain representatives came to town for the purpose, and a conference was held at Whitehall, the Board being represented by Dr. Mouat, Mr. Basil Cane, and Mr. Smith, architect to the department. The main question for decision appears to have been whether the block system should be adopted, or a building erected after plans made by the local architect. Dr. Mouat of course advocated the block system, and Mr. Smith followed suit; Mr. Cane commended the plans of the local architect, but at this meeting seems to have done nothing and advised nothing. A week afterwards the local authorities held their usual meeting at Sheffield, Mr. Basil Cane and Mr. Davy attending from the Local Government Board. It is not necessary, nor would it be interesting, to reproduce the discussion in detail; it suffices to record that the energies of Mr. Cane were exclusively directed to the support of the local architect and the condemnation of the block system in principle and in detail. The block system would, according to Mr. Cane, "render the working of the establishment very inconvenient," "its internal contrivances would be bad," and, moreover, "it would be a thing to laugh at with two storeys at one end and three storeys at the other"! It is difficult to read with gravity these profound official lucubrations. They appear, however, to have had great weight with the local authorities, Dr. Mouat and the architect of the Board being absent, for the advice of the former gentleman was (except as to the hospital) entirely disregarded: the lay inspector won the day against his colleague of the Medical Department, and the designs of the local architect are to be adopted. We do not care to canvass here the merits of the block or any other system, though they have long since been ably summed up by many competent sanitarians, but we desire to call attention to the lamentable want of organisation in a public department, the officers of one branch of which are permitted to stultify the skilled opinion and advice of those of another branch, and that in the absence of the latter. As long as matters are thus administered at Gwydyr House, the less local authorities have to do with the central office the better.

THE "QUARTERLY REVIEW" ON DRUNKENNESS.

An article in the current number of the *Quarterly Review* on "Drink: the Vice and the Disease," deserves something more than a passing notice at our hands. In consists of a forcible and striking account of the ravages of drunkenness in England, and of the moral and physical devastation, individual and social, which results from the English custom. An interesting review of the habits of the upper and middle classes shows how strikingly an average moderation has increased among them, and that in spite of the enormous increase in the importation of wine since Mr. Gladstone removed the barrier of high duty. The increased consumption is mainly of light wine, and society has not been tempted by its cheapness beyond resisting power. But it has been far otherwise with the poor. "Drunk as a lord" was the intelligible, however disgraceful, saying of the olden time; now it is "drunk as a beggar." The increased temptation to which the lower classes have been exposed has been accompanied by no increased power of resistance, rather by an immeasurable decrease. Fatal mistakes have been made in the legislative enactments for the benefit of the poor. The Beerhouse Bill of 1830 added fuel to the flame of inebriety, and "may justly be credited with the boundless increase of that which it was intended to modify." The evidence of the fearful extent and effects of intemperance in this country is traced by the writer through the reports of the various Commissions which have collected facts and opinions on the subject, and their terrible details need no adventitious colouring; they are, indeed, incapable of exaggeration.

To what measures can we look for relief, for any remedy for this "topsy-turvy rottenness of the State"? The hopelessness of expecting self-reformation on the part of the drunken working classes is becoming increasingly evident, so long as the circumstances of their life and temptations remain unchanged. Mental education is powerless to reform the moral fault. "If the drunkenness of the day be not sufficient to raise a public opinion against itself, neither School Board nor Church will ever do it. If the facilities for excess are confessedly so superabundant as to entice a poor fallible child of man beyond his powers of endurance, why are they not curtailed? Here we touch the root of the matter, and know well the outcry the mere suggestion will raise. Is not the poor man to be allowed to drink as much as the rich man? Is the liberty of the subject to be curtailed? But why *tempt* the one more than the other?" It is to the *number* of these places, the writer urges, and with justice, that public attention must be directed, and he believes that if we could close all the beershops, and limit the number of public-houses, the mischief would be to a great extent stayed. He cites the example of the self-reform of Gothenburg as an example worthy of study, if impracticable for complete imitation.

The main features of dipsomania are sketched with equal vigour and fidelity, and the need for legislative interference for its restraint is not only concurred in, but urged with great force. "The man who *cannot* refrain from that which renders him periodically mad is as irresponsible as the chronically insane, and must be treated accordingly. His own will being in abeyance, it is only by the act of another's will, and that supported by the law of the land, that he can be rescued and his family relieved." The relation of the vice to the disease is clearly shown. "The unprincipled man lapses into the helpless man. The vice entails the disease, and yet the vice cannot be met by the medical profession, and the disease is not met by the law. The vice can never be cured by the law alone, and the disease never cured by the doctor alone."

Finally, the writer reviews the objections which have been urged against the legal detention of the dipsomaniac, and shows how conclusively they may be answered. He points out especially how effective legal provision is, even when not employed, the knowledge of its existence having been found sufficient, in America, to induce the voluntary retirement of the sufferers. It is urged that neither with this question nor with the larger one of intemperance, can delay be productive of anything but harm. "It is simply a question of which the country can best afford: to let the evil gather strength with every year, or to grapple with it earnestly and at once."

THE MEDICAL WOMEN QUESTION.

Alderman Chamberlain, the Mayor of Birmingham, is so deservedly popular amongst his fellow-townsmen, and his civic reign has attracted so much notice and won such high praise throughout the country, that any measure advocated by him is certain to receive very careful consideration. The medical education of women has never met with a more able and influential supporter than Mr. Chamberlain, who appears to have set his heart on opening to his fair clients the doors of the Birmingham Queen's College. We recently announced the decision of the College against the Mayor's proposal, and it was at one time believed that the ladies' friends would accept that decision as final; but the recent general meeting of the Queen's College governors has dispelled the illusion. In the absence of Lord Lichfield, the president, the Mayor was voted to the chair, and after an able speech, he concluded by moving a resolution requesting the Council to reconsider its recent decision. The proposition was supported, amongst others, by Mr. George Dixon, M.P., but eventually it was withdrawn. The discretion of the retreat had been made very obvious by the disparity of numbers on the two sides, and the wisdom of the women's advocates would have been still more conspicuous if their leader had not for a moment lost his equanimity and indulged in taunts of trade-unionism and threats to establish a rival institution.

The Council of Queen's College had no other course open to them than to decline the Mayor's overtures for the admission of women to Queen's College; for the whole body of teachers in the Birmingham Medical School had declared themselves unable, by a very decided majority, to conduct the proposed experiment. The Birmingham Medical School has an exceptional constitution. The systematic teaching is conducted by a body of professors and tutors at Queen's College; while the General Hospital and the Queen's Hospital are amalgamated for purposes of clinical instruction, their staffs forming one clinical board, and the pupils attending alternate sessions at the two hospitals — an arrangement which widens the basis of the school, increases the number of teachers, and furnishes immense scope for clinical observation. In the presence of the formidable party headed by Alderman Chamberlain, the members of the Birmingham

Medical School have taken counsel together. They do not oppose the medical education of women, but they have declared that, as a school, they are not prepared to undertake it. The women's advocates plead in the name of freedom, and the Birmingham medical teachers simply resent coercion. Medical education, which has never been easy, is in the present state of knowledge so intricate, and demands, on the part of teachers and pupils, so much continued and persevering attention, that it admits of no exciting diversions or questionable experiments within the precincts of a school. The women's advocates are a wealthy body, and they may found their own school, as others have done. If the Council of Queen's College and its consolidated body of medical teachers persevere in their endeavours to promote the interests of the medical profession, they will not lack support. They have wisely declined a very tempting offer from a great political party, and are to be congratulated on the moderation and perfect temper in which they have conducted the delicate negotiation.

THE SANITARY CONDITION OF HULL.

OUR remarks on the high death-rate lately reached in one of the districts of the town of Hull has brought us considerable correspondence, and a formidable collection of newspaper cuttings and reports of recent meetings of the Sanitary Committee of that town. We have patiently examined the large amount of evidence thus afforded, with a view of arriving at some definite conclusion as to the real state of the sanitary affairs at Hull and the amount of responsibility resting with the sanitary committee. To render our remarks more impartial, we have limited our criticism entirely to the statements of members of the Sanitary Committee. At a meeting of the Hull Board of Health, Sept. 30th, Mr. Chapman alluded to letters that had appeared in the newspapers with respect to the outbreak of fever in Blyth-street; he denied that the houses were fever beds, and stated fever raged in more places in the town than in Blyth-street, and that Blyth-street was not so bad as had been represented. Mr. Waller remarked "that all the nonsense which had ever been written or spoken, as to drainage being a source of fever, there had never been so much as in the case of Blyth-street." He had visited the house in question. "In the front room, which was about ten feet by six feet, there was a bed, and on it three or four children. In the back room, which was about the same size, there was a bed the clothes of which nearly touched the fireplace, and on this bed there had been people ill of fever. In the back yard there were all sorts of dirt. In the house there had been living a man, his wife, six children, a lodger, and very often the man's mother. The odium fairly belonged to the people who were living in the house." Dr. King described the condition of Blyth-street, and said that if Mr. Chapman had been in the house, he (Dr. King) had; where there were eight persons ill of fever he would have felt that it was a serious matter, and attention ought to be given to it. The drain in Blyth-street was stopped with a brick. The surveyor explained that "the Board had as yet exercised no control over Blyth-street; some few years ago the private streets were taken in hand, and eleven out of seventeen miles had been constructed." The medical officer (Mr. Holden) "believed the fever was due to the bad drainage. His idea was, that bad drains brought about a bad condition of property and bad tenants; until the drainage of Blyth-street was remedied they could not well expect a better state of health in the district." The statements of Dr. King, the surveyor, and the medical officer of health thus attribute the outbreak to the bad condition of the drains; whilst Mr. Waller throws the blame on the dirty and crowded condition of the tenements. Whichever view is right, the sanitary authority stand equally charged with neglect. Surely the sanitary authority ought to have all the drains in the streets constantly examined, so as to ascertain if they are blocked or not. Nor is it any excuse to say that houses have become overcrowded, and their back-yards are filled with dirt. What can their inspector of nuisances be doing? Under these circumstances Mr. Chapman's statement that fever raged in more places in the town than in Blyth-street is probably not exaggerated. For it appears that an excess of mortality has arisen in the town during the present year, the excess in scarlet fever alone being 200. The general tone of the Hull sanitary authority, as gathered from the published reports of their meetings, is apathetic; there are a few members, however, who seem disposed to be energetic and liberal. And we are pleased to see that Mr. Blackburn proposed to appoint a medical officer of health for the borough at an adequate salary, who should devote the whole of his time to the duties of the office. (The present officer receives, besides a few small fees, the munificent sum of £20.) The proposal was referred to a committee! From the correspondence and leading articles in the local papers, it would appear that the inhabitants are taking more interest in the sanitary matters of the town than the authorities; and we are surprised that the graphic descriptions of the numerous sanitary evils stated to exist in Hull have not excited the attention of the authorities of Gwydyr House. A visit from one of the Local Government Board medical inspectors is urgently required, and a thorough and impartial investigation of the causes producing the present high rate of mortality in the town should be carried out without delay.

THE NEW ENTRIES.

ON the 24th of March, 1710-11, Addison published a letter in the *Spectator*, which commenced as follows:—"I am sometimes very much troubled when I reflect upon the three great professions of divinity, law, and physic; how they are each of them overburdened with practitioners, and filled with multitudes of ingenious gentlemen that starve one another." If such was the state of things one hundred and sixty years ago, how great would be the distress of the "prince of essayists" if he were among us now! The number of medical students that have entered annually at the metropolitan schools has gradually increased in ten years from one thousand to more than seventeen hundred. How appalling would these numbers be to Addison, who affirmed that it might be laid down as a maxim that when a nation abounds in physicians it grows thin in people, and who even went so far as to suggest that the solution of the difficulty which presented itself to the mind of Sir William Temple why the northern hive does not send out such prodigious swarms as it did formerly might be found in the comparatively modern institution of medical practitioners. These insinuations were, of course, never intended to bear literal interpretation or close examination. Some of the increase in the number of entries into the profession is, of course, due to the larger demand. There are many departments of the State and the public service in which large numbers of medical men are now constantly employed. The Vaccination Act, the Factory Act, the Public Health Act, and many other legislative enactments for the preservation and maintenance of the public health, require for their proper and efficient administration the unremitting services of many trained medical men. But this will not account for all the increase. There is no avoiding the fact that the medical profession is gradually becoming overcrowded, and a similar state obtains, we believe, in the professions of law and divinity. The reason of this is not clear in a commercial community like ours, where it has been stated there are few so dull and heavy who may not be placed in stations of life which may give them an opportunity of making their fortunes. The clamour for professional life is not unfrequently the result of a miscalculation of a boy's aptitude and abilities, and, to satisfy the whim of a friend or parent, many a young man is placed in the medical profession against his natural inclination. It is not, therefore, a matter of surprise that there are some failures; but, on the other hand, it must not be forgotten that honest industry is sure of its reward. A man may not rise to eminence or to wealth, but with good health and a willing heart one who is really determined to act uprightly will not fail.

ANTISEPTIC SURGERY AT THE CLINICAL SOCIETY.

Although the discussion at the last meeting of the Clinical Society on antiseptic surgery was, on the whole, extremely weak, it showed two things—first, that the opinions of those who took part in the discussion were very unsettled; and, secondly, that notwithstanding this, there is on the part of most surgeons a general desire to give the system a full and fair trial. Hitherto the statements have been for the most part plain, a little vague perhaps, but calmly made. We have not yet heard the extravagant praises of the rabid partisan, nor the wholesale condemnation of the obstinate conservative. It is to be hoped, however, that at the next meeting statements more definite than any yet advanced will be forthcoming, for Mr. Pick says that he does not think that antiseptic dressings prevent suppuration, whereas Mr. Holmes, his senior colleague at St. George's, has no doubt that carbolic acid does prevent it. Mr. Lister's own opinion accords, we believe, with that of Mr. Pick. The most weighty remarks were those of Mr. De Morgan, of Middlesex Hospital, who alleged his belief that a great part of the success of the antiseptic system was due to the extreme care on the part of the surgeon, both in the dressing of wounds and in the general hygienic measures. Mr. Maunder entertained a similar opinion. Mr. Heath and Mr. Thomas Smith, who were made partial converts to the faith in the antiseptic system by Mr. Lister's brilliant demonstrations at Edinburgh, urged that it was useless to draw any conclusions from the particular mode of dressing, unless all the minute details of the plan were fully carried out.

Such was the result of the last discussion. Let us hope that the next, at which Mr. Holmes has promised to read a paper on Antiseptic Surgery, may be more profitable.

THE ROYAL MILITARY ACADEMY, WOOLWICH.

As everyone knows, this is the training college for the scientific branches of the army—the Royal Engineers and Artillery Corps,—just as Sandhurst is for the remainder of the army. The Board of Visitors appointed to inspect the former establishment have just issued their report for 1875. On turning to this document, we expect to encounter certain recommendations which have by this time become stereotyped expressions. The present Board, for example, refer to the representations of their predecessors in regard to defective accommodation. It appears that as many as three or four cadets are crowded into one room, and that, for want of quarters near the barracks, the servants have to reside in some of the most unhealthy parts of the town. As regards the first, setting aside the matter of health and propriety, we do not believe it possible for much reading or mental work to be done under such circumstances, and, as the cadets' parents have to contribute to the funds of the institution, it might fairly be expected that every cadet would get, what he is surely entitled to, a separate room. And, as regards the second point, the Board of Visitors concur with the medical officer in thinking that the cadets are more exposed to the risk of contracting infectious diseases than they need be, by the frequent passage of the servants daily from their lodgings in the town to the Royal Military Academy. The Visitors were unable to ascertain that any evil had arisen from the exposure to which the cadets are subjected in winter time, by having to pass through the open air to the bath-rooms attached to the old building, and, pending the execution of their proposal for accommodating each cadet with a room, where bath-rooms under the same roof would be provided, they think the adoption of any temporary expedient unnecessary. No case of disease from immoral causes has come to the knowledge of the medical officer during the year under report. The Visitors are satisfied, after careful inquiry, that a good tone generally prevails amongst the cadets, "but there are still one or two silly distinctions kept up between the older and younger cadets, which, as they do not assist in maintaining discipline, and one of them is likely to injure health, ought to be done away with." The Visitors, while indicating a remedy for certain trifling defects, are satisfied that the system of cadets' messing, and the quantity and quality of the food supplied, are quite satisfactory.

SPREAD OF FEVER BY TAILORS.

The vivid and realistic autobiography of "Alton Locke, Tailor and Poet," first brought into view the fearful risk which attends the practice pursued by most tailors of putting out the whole or some portion of their work. It is next to impossible for an employer to exercise any active control over the homes of his workpeople. These homes are often in the worst neighbourhoods, crowded and filthy, and liable to become at any time centres of disease; and the customer of even a fashionable West-end tailor has no security that the coat he receives has not a few hours before been impregnated with the atmosphere of scarlet fever, or even in actual contact with the victims of the disease. Similar conditions prevail in the dressmaking and shoemaking trades, and it is impossible to doubt that many epidemics of fever for which the physician is now unable to account, would become intelligible if we could trace the previous history of the clothes the patients had worn.

These considerations, which we have often urged, were forcibly recalled to us the other day by a conversation with a respectable tradesman in Soho, who for some time past has had the misfortune to have as lodgers a party of journeymen tailors. The house is of the better class, and the journeymen were in the employ of a well-known West-end tailor, who paid good wages, and was particular about the place in which his workpeople lived. His superintendence clearly could extend no farther. The workpeople in question were, however, extremely dirty in their habits, and a close and disgusting smell was generally perceived in passing their door. Some months ago a case of disease, the nature of which we have been unable to trace, occurred among them, and quite recently a death has taken place. In the latter case no medical man was called in, and the death was registered as from bronchitis. The people of the house, however, believe that the real disease was scarlet fever, and say that one of the women confessed as much, and admitted that they had concealed the fact from fear of losing their employment. Proof in a case of this kind is very hard to obtain, and perhaps the story may be founded in error. But its possibility cannot be denied, and is sufficient to inspire us with very unpleasant ideas.

Surely some remedy could be found for this very obvious public danger. The Act which regulates workshops does nothing to meet it, and there would seem to be only two alternatives open—namely, to forbid employers from putting their work out, which would be difficult, if not impossible; or to provide for the registration and sanitary inspection of all houses or lodgings in which the making up of wearing apparel for sale is carried on. The latter remedy seems to us to be the true one.

OUTBREAK OF ENTERIC FEVER AT UPPINGHAM SCHOOL.

We regret to announce the occurrence of a serious outbreak of enteric fever at Uppingham School. The first case occurred on September 21st, and from that time to the present thirty boys have been affected, four of whom have died. The outbreak commenced in the house of one of the masters of the lower school, occupied by sixty persons; the previous health of the house had been good, though it is stated that a boy had died of enteric fever last June. The total number affected in this house, so far as we have been able to ascertain, is eleven. In another house containing forty-four inmates, there are nine cases. The first of these sickened on 1st of October. In a third house a boy sickened on 2nd of October; this case terminated fatally; no other case occurred in this house. In a fourth house one boy, two daughters of the master, and the matron fell ill. All these cases occurred about the 2nd of October. The medical attendant of the school from the first pronounced the disease to be "enteric fever," and, indeed, the cases seem to have been well-marked. In all the houses the cesspit system has been adopted, and the water-supply is in dangerous proximity. In some of the houses the dormitories are supplied with water from the cisterns which supply the waterclosets. The town of Uppingham, with the exception of two or three cases, is free from enteric fever. The medical officer of the school dealt promptly with the outbreak, and the cases were removed to the sanatorium. It is satisfactory to be able to state, that since the 13th inst. no fresh cases have occurred.

Two points suggest themselves to us. First, the suddenness of the outbreak and the short period intervening between the infection of the different houses, pointing, we think, to one common source of mischief. Secondly, the proximity of the cesspits to the water-supply, and the cisterns for the drinking-water being over the closets. These facts afford, we think, strong evidence that the water-supply of the various houses affected has been contaminated by the introduction of some specifically infected material, and that the inmates of these houses received the poison nearly about the same time. It will be interesting to ascertain if there is any connexion between the case of enteric fever last June, at the end of the half, and the present outbreak this term—how were the infected stools in that case disposed of? A strict inquiry has been demanded by many of the parents, and we shall await with interest the official report of Mr. Haviland, the medical officer of health for the Northamptonshire combined districts, which we suppose will, in due course, be made to the sanitary authority of the district.

THE ARTISANS' DWELLINGS ACT IN BIRMINGHAM.

The adoption of the Artisans' Dwellings Act in Birmingham is a fact of no small significance. It indicates that the attention of the authorities of a great manufacturing centre are alive to the necessity of acting up to the old Roman dictum, "Salus populi suprema lex," and that they are prepared to carry out, even at a cost of half a million of money, a sanitary measure which has for its main object the pulling down of a number of houses which are unfit for human habitation, and the opening up of a district which now is nothing but a hotbed of dirt, fever, and foulnes with good roads and good drainage.

It is creditable to the public spirit of the corporation that this measure was agreed to unanimously, and it is to be hoped that no adverse criticisms on the part of the falsely called "economical" party will prevent the scheme presented by the sanitary committee being carried out in its entirety. Although all praise is due to those who have thus succeeded in passing this wise measure of sanitary reform, it must not be forgotten that no small share of the credit of it must be awarded to the medical officer of health, through whose report on the condition of the affected district the sanitary committee proceeded to act, and to him should be accorded the warmest thanks of the community. It is not a long time ago that Birmingham was without a medical officer of health altogether, the people dwelling in a state of happy ignorance of the risk they were incurring by the neglect of proper sanitary laws. However, they were aroused from their lethargy by the outbreak of a formidable epidemic of small-pox, and in a panic they appointed Dr. Hill as medical officer of health. Since his appointment a thorough sanitary inspection of the various wards of the town has been made, many nuisances have been removed or abated, cesspools have been condemned, the water-supply has been placed in the hands of the corporation, hospital accommodation for those affected with infectious diseases has been provided, and now, to crown the whole, a part of the centre of the town, where property is most valuable, is going to be swept away because the medical officer of health declares it to be "an unhealthy area," the rate of mortality in that quarter of the town being more than double what it is in some of the better built and sewered wards. The very fact that, of the three thousand preventable deaths which occur annually in Birmingham, an unusually large proportion are afforded by this very district, must convince anyone of the wisdom the corporation have shown in listening to the recommendations of the health officer of the borough.

SIMLA, THE INSANITARY.

By all accounts, Simla can no longer be reckoned the chiefest among the health-resorts of India. Notwithstanding its great natural advantages of position and climate, it is, to borrow an expression from our contemporary, the *Indian Medical Gazette*, fast becoming used up, and is a place to be avoided rather than sought by invalids or healthy people. After repeated warnings from medical officers and others as to what must accrue from a long-continued disregard of cleanliness and neglect of all sanitary precautions, and the frequent prevalence of the so-called "hill-diarrhœa," Simla has been quite recently visited by a severe outbreak of cholera. The fact is, the place has become filthy with the accumulated filth of years, and Indian officials are naturally alarmed at finding the cholera betaking itself, like themselves, from the plains to the hills for a change. By the latest accounts received in this country it would, moreover, appear that cases of cholera were still of frequent occurrence in various parts of India. It was very prevalent in different districts of the Madras Presidency, its attacks being almost entirely confined, however, to the native races.

KNIGHTSBRIDGE BARRACKS.

In reporting on the sanitary condition of the Knightsbridge Barracks last summer, we suggested that probably they would themselves solve the question of removal by falling to pieces. We learn from the *Pall Mall Gazette* of Tuesday that our prophecy is in part fulfilled, a portion of the barracks having given way last week. We have pointed out on several occasions the ineligible nature of the present site, not merely as a question of public convenience, but of sanitary principle. We hope, therefore, when the barracks are rebuilt another site will be chosen. If it is absolutely necessary to have barracks in the park, we would suggest that on the north side of the Serpentine a site much better adapted for the erection of spacious and commodious buildings is available. We consider it would be impossible to build barracks with anything like adequate accommodation on the narrow strip of land available at Knightsbridge.

WHERE IS THE WARRANT?

Our contemporary, the *Broad Arrow*, has this question as the heading of a long article on the Army Medical Service, but it is apparently unable to cast any light into the particular pigeon-hole into which that document has been presumably officially laid aside during the Parliamentary recess. However much the Minister for War may find the policy "to rest and be thankful" an agreeable one, the members of the department concerned do not, and they will certainly expect that the intentions of the Government in regard to them will be declared at the earliest practicable date after the meeting of Parliament. Meanwhile, we must suppose that Mr. Gathorne Hardy has kept his own counsel, for no one seems to know what to expect. In his replies to various deputations and in his answers to members of Parliament, he has tied himself down to nothing beyond declaring, in a general sort of way, that he is giving the subject full consideration, with the object of doing something. He can, when he chooses, not only answer the question, "Where is the Warrant?" but "What is it?" also. He has, if we remember rightly, intimated that this subject forms but a portion of the changes affecting the army generally, about which he has now been so long deliberating.

DESICCATED BLOOD.

Some observations on desiccated blood were recently communicated to the Academy of Sciences of Paris by M. Le Bon. If blood is reduced, by simple evaporation, to a solid, the resulting powder is absolutely insoluble and indigestible; it may be macerated for twenty-four hours with a solution of pepsine and acid without being altered. But by evaporation at a low pressure and at a temperature which does not exceed that of the body, M. Le Bon has succeeded in obtaining a powder which, even after being kept for eighteen months, is readily soluble in water, and yields a red solution which has exactly the properties of defibrinated blood, is precipitated in the same manner by heat, and shows under the spectroscope the absorption bands of hæmoglobin. The powder is as soluble in an acidified solution of pepsine or in simple water, a fact which sufficiently proves its digestibility. The therapeutical application of this preparation are important enough if its characters are uniform.

ENTERIC FEVER IN CHESTERFIELD.

A sudden outbreak of enteric fever has occurred in Chesterfield and the immediate neighbourhood. No less than seventy cases are already under treatment from this disease, and a few deaths have taken place. The heavy rains have rendered houses very damp and unhealthy, wells that were insufficiently protected from surface pollution have become impregnated with vegetable *débris* and other refuse, and uncovered ashpits converted into obnoxious cesspools. The general water-supply is also of a doubtful character. The Chesterfield Water Company have no filtering medium, and the catchment basin is very steep; consequently, all animal and vegetable refuse is carried along with the stream to the reservoir, and from thence to the various outlets. This is the real explanation of the outbreak.

Every infected house, yard, drain, and ashpit has been thoroughly disinfected under the superintendence of the inspectors of the medical officer of health; and the stools of the sick, on the recommendation of the medical officer, have been almost in every case disinfected before they were removed from the sick-rooms, and then buried in the gardens. Isolation cannot be completely adopted, as the sanitary authorities are not disposed to provide mortuaries or hospitals. Bills have been freely distributed throughout the district, and posted in every street and corner.

DEAD BODIES CONCEALED.

There cannot be two opinions as to the misconduct of undertakers who, instead of burying the bodies of infants committed to them for that purpose, pocket the fees and conceal the corpses. The severest punishment which can be visited upon offenders of this class will scarcely satisfy justice or appease public indignation. The putrid remains are a nuisance and source of peril to the living. Perhaps the only measure sufficient to meet the case is to give inspectors of nuisances power, and instruct them, to enter and search the premises of every undertaker at uncertain periods. The practice of delay is probably very common, and this leads to the concealment. Meanwhile something would be gained, and many malpractices restrained, if not prevented, by simply adding another column to the form required to be filled up by the local registrar of deaths, attesting the fact, place, and date of interment. Let every certificate given by a registrar to the friends of a deceased person be returnable to the *same* registrar within a specified number of days, signed by the sexton or other official in charge of the burial ground; and enforce registration in all instances of death and burial, and in all cases of *burial* without "death," so as to cover the case of still-born children.

The Keighley Board of Guardians cannot be said to have as yet elicited much sympathy or encouragement from the treatment given to the manifesto against the Vaccination Acts which they continue to forward to other boards throughout the country. The answers received include varieties of the forcible, of the humorous, and of the bantering style. Thus the Merthyr Tydvil Guardians thought the Keighley Board had gone mad, and expressed a hope that the law would bring the members to their senses. The Salford Board had resolved that the Keighley Guardians were fit subjects for a lunatic asylum, and ought to be confined in one at their own cost; they considered even a halfpenny for postage too much to expend on lunatics. The York and Doncaster Guardians had ordered the circular to be thrown under the table. The Canterbury and Halifax Guardians said it was unworthy of consideration. We much fear, however, that these gentle rebuffs will have no effect on the representatives of the Keighley ratepayers.

We announced a few weeks ago that the Strand District Board had memorialised the Metropolitan Board of Works on the subject of public mortuaries. The memorial asked the Board to seek Parliamentary authority to erect such buildings in the metropolis, together with compulsory power for the purchase of sites. We are sorry to find that the Metropolitan Board have declined to accede to the wishes of the memorialists. It must be admitted that the difficulties of forwarding such a scheme are great, but still they are not insuperable. The question will doubtless be ventilated in Parliament next session.

WITHIN the last few days Colonel Cox, on behalf of the Local Government Board, held an inquiry into the sanitary condition of Dewsbury. The central authority took action in the matter in compliance with a formal complaint under the provisions of the Public Health Act of this year made by certain of the inhabitants. The complainants allege that the Town Council are in default in not providing the town with proper sewers, and that the public health had suffered in consequence. A good deal of evidence on both sides of the question was given. The official report of the investigation ought to prove an interesting one. We shall probably refer to it when it makes its appearance. It should be generally known that ratepayers, dissatisfied with the conduct of their representative sanitary authority, can obtain an inquiry into any specified default on making the necessary application.

IN London last week 1563 deaths were registered, including 34 from measles, 127 from scarlet fever, 11 from diphtheria, 47 from whooping-cough, 26 from different forms of fever, and 41 from diarrhœa. No death from small-pox was recorded. It will be observed that there is a considerable increase in the mortality from scarlet fever. The disease has been extending in the metropolis for some weeks past, and we have in another column commented upon the extension. Different forms of violence caused 60 deaths in the period. In the large institutions 255 deaths occurred. The Asylum District Fever Hospitals contained on the 23rd inst. 330 patients, 253 of whom were under treatment for scarlet fever.

FROM the *Western Morning News* we learn that a small place called Buckfastleigh has been visited by an epidemic of scarlet fever of great severity. We are not surprised at the visitation if what our contemporary says of the village is true. It does not, we are told, possess a common sewer. The majority of the inhabitants reside in courts and alleys; they have no privies, but keep their daily refuse of every kind in a pail, and at night deposit it either in the garden or in the river. Into the stream, too, the refuse of a most offensive manufacture finds its way.

THE epidemic of fever on board the *Cornwall* still continues. Six cases have been sent to St. Bartholomew's Hospital, and eight fresh cases have been admitted at the Seamen's Hospital during the past week. Most of the patients at Purfleet have been sent to the hospital-ship *Rhin*, which has been placed at the disposal of the *Cornwall* authorities by the Port Sanitary Committee of the Corporation. Thus it appears that up to the present time 80 out of a total of 245 boys have been attacked.

IT is asserted by M. Vidal that the addition of chloral to a solution of morphia renders it much less liable to spontaneous change. This fact, if it be true, is important. The alteration which concentrated solutions of morphia undergo renders their strength variable and uncertain if they are laid by for a time. M. Vidal adds to the solution a quantity of chloral equivalent to twice the weight of the morphia it contains. He affirms that the injection of this mixture is not painful.

WE gather from the *North British Mail* that a virulent epidemic of scarlet fever prevails in the villages of Busby and Cathcart. Our contemporary states that in some houses almost every member has been seized in turn, while in and around Busby the mortality up to the present time has amounted to about 20 per cent. of the cases. The epidemic is also making itself felt in adjacent districts.

DR. STORRAR has recently been re-elected a member of the General Medical Council. Dr. Storrar was first appointed by the Senate of the University in November, 1858, for the period of five years. Since the expiration of that term of office the appointment has been annual.

REPORT
OF
The Lancet Sanitary Commission
ON THE
DWELLINGS OF THE POOR.

No. V.—THE CITY OF GLASGOW.

THE municipal authorities of Glasgow have greatly distinguished themselves by the efforts which they have made to improve the sanitary condition of the city under their charge. Their water-supply is the best in the country, and the aqueduct from Loch Katrine to the city is a work in every way worthy of one of the richest cities of the kingdom. Good as it is, however, we understand that arrangements are being made to supplement it; and that Loch Lubnaig, to the north of Callender, is to be tapped for the purpose of additional supply. Notwithstanding the unlimited supply of absolutely pure water, the death-rate of the city has continued to be above thirty per thousand. This high death-rate is attributable in some degree to the character and occupation of the inhabitants, and to the fouling of the atmosphere by the innumerable factory chimneys. Mainly, however, it is due to the density and overcrowding of the population—a fact which is forcibly illustrated in the following paragraph from a speech by Sir James Watson, made in 1860, taken from a pamphlet published last year by Baillie James Morrison, one of the most enthusiastic of Glasgow's sanitary reformers.

> "From each side of the streets in the districts referred to (i.e., Gallowgate, High-street, Saltmarket, Trongate, &c.) there are narrow lanes or closes, running, like so many rents or fissures, backwards to the extent of sometimes 200 or 300 feet, in which houses of three or four storeys stand behind each other, generally built so close on each side that the women can either shake hands or scold each other, as they often do, from the opposite windows. ...... Throughout the whole of these districts the population is densely crowded: in many of the lanes there are residing in each not fewer than 500, 600, and even 700 souls; and in one case we observed 38 families, or nearly 300 persons, occupying one common stair."

> Mr. Morrison continues: "This, then, was the condition in 1865 of what may be designated 'Ancient Glasgow,' covering an area of about 88 acres in the centre of the city, where a population of 51,304 was packed together at the average rate of 583 persons to the acre, in upwards of 10,000 houses, the walls of which were permeated with disease. The population of the whole city in 1865 was 423,723, so that fully 12 per cent. occupied houses in every sense of the word unfit for human habitation, rapidly spreading moral and physical deterioration. The death-rate over the whole city was, as might be expected, 32·8 to the 1000, which increased in 1869 to 34 to the 1000; and the average death-rate of the 88 acres alluded to was 38·64 to the 1000. These figures still, however, fail to convey an adequate idea of the rapidly increasing over-density. The improvement scheme comprises 40 areas, in the worst of which, and in portions of the others, the population was housed at the rate of 1000 to the acre, or 640,000 to the square mile. In these plague-spots and fever-dens the death-rate was as high as 52·21 to the 1000 in 1865. In 1870, before demolition commenced, it rose to 70 in the 1000."

It will be seen, therefore, that the overcrowding in the old parts of Glasgow in 1865 exceeded anything which we have in London, where the density of the population nowhere exceeds 430 persons per acre. The number of houses per acre in Glasgow appears to a London reader extraordinarily great, but it must be borne in mind that in the Scotch towns a house corresponds to what we should call a tenement. Every apartment or set of apartments abutting on a common stair is spoken of as a house.

In consequence of the activity with which the improvement schemes have been pushed forward much of the overcrowding has disappeared, but that which remains is amply sufficient to give one an idea of the state of things with which the authorities have had to grapple. We visited the *Saltmarket,* one of the oldest parts of the city, and a part which a century and a half ago was occupied by decent and respectable inhabitants. Readers of "Rob Roy" will remember that Baillie Nicol Jarvey had his house in this quarter of the city. These old houses are solidly built of stone, and the attentive observer will not fail to recognise here and there the evidences of departed respectability. They are, on an average, about three storeys high; the houses of ten and eleven storeys, which are common enough in Edinburgh, not being found in Glasgow. The rows of houses almost touch each other, and every house seemed to us to be literally overflowing with inhabitants. Every house under a certain size in Glasgow is subject to police supervision, and we were enabled to accompany the police officers in their round of inspection. It was evident that the visits of the police were of common occurrence, since our presence seemed to pass almost unnoticed by the inhabitants. The door of every house is decorated with a police ticket, ordinary houses having a square, and lodging-houses a circular, ticket. Upon this ticket is written the cubic space of the house and the number of persons which it is licensed to contain. The authorities allow one adult inhabitant to every 300 cubic feet of space, a child (under eight years and a half of age) counting as half an adult, and being allowed 150 cubic feet of space. The inhabitants of the houses are, for the most part, the lowest class of Irish, and it is needless to say that they live in almost inconceivable squalor and wretchedness. The windows of the houses are, as a rule, small, and the amount of light, owing to the thick atmosphere and the close proximity of the dwellings, extremely little. In the matter of light Glasgow is probably worse off than London. The first house we visited had a cubic space of 2743 feet, and was licensed for nine adults. In the second, of 2295 cubic feet, seven persons were living; and in a third, a lodging-house of one room, containing 2106 cubic feet, there were five beds, touching, or almost touching, each other, licensed to hold nine people. This state of overcrowding, with the dirt and other evils which are its necessary consequences, were everywhere observable; but, although the density of population was far greater than is to be found even in Soho and St. Giles's, we could not but think that the inhabitants were in many respects better off. In the first place, the authorities seem to have shown themselves very capable of dealing with and making the best of matters as they existed—a very important thing, since improvement schemes, involving legal formalities, demolition and reconstruction, necessarily take years to accomplish. The method of ticketing the houses and subjecting them to police supervision seemed to us, though a small matter, to be a most admirable system, and one which we would recommend to the notice of Mr. Cross, since without it the amount of overcrowding would undoubtedly be much greater even than it actually is. Then, again, these old dwellings are immeasurably superior to the London lodging-houses in the matter of water-supply. On every landing, at least, there is a water-tap, from which any amount of pure water may be obtained with a minimum amount of trouble. Close to every tap there is a sink for waste and slops, and the waste pipes run with the rain-water pipes into open drains. These old houses are, happily, for the most part, without subterranean sewers. As to waterclosets, they are practically non-existent in these dwellings, and one very curious result of the displacement and removal of the inhabitants to new quarters has been to make the use of waterclosets more general, and so to increase the pollution of the Clyde. In the "Information" relating to the Glasgow improvements, laid before Parliament at the beginning of this year, the history is given of 263 families whose movements, consequent on the demolition of their old dwellings, had been traced. Among other facts, it is stated that "only 12 of these had watercloset accommodation originally, but 35 had such accommodation in their new houses—that is, whereas only 4½ per cent. of the families whose houses were demolished sent their excreta into the sewers before the demolitions, nearly 13½ per cent. did so afterwards....... As to the immediate effect of the change from privies and ashpits as the method of excrement disposal upon the families themselves, two things must be taken into consideration: (1) that, from the close occupation of the ground in the old localities, for the most part no site was to be had where a privy or midden could be placed, so as not to be a nuisance and a source of injury to the health of the inhabitants; (2) that, of the 35 families who found themselves supplied with waterclosets after these operations, only 13 found them in their houses; the remaining 22 found them on the stairs."

What becomes of the excreta of the remaining 228 families we are not informed in the parliamentary paper. Much of it, no doubt, finds its way into the public privies which the authorities have erected wherever a suitable situation could be found. We inspected one of these privies standing in a court in "Old Vennell." It resembled in external appearance the ordinary cast-iron London urinal, without door, but having a circuitous entrance at either end to screen the occupants. There was accommodation for five persons, and a partition down the centre divided the part used by males from that devoted to the necessities of females and children. The excreta are received into a simple iron pan beneath the seat, and the pans are emptied and cleaned daily by the public scavengers. The number of these privies is probably quite inadequate for the number of inhabitants in these old quarters. The gutters and kennels are probably largely used, and possibly the cry of "*Gardez l'eau!*" may still, as it did in Smollett's time, warn the passer-by of the accident which may befall him from the upper windows. In these old dwellings the one evil seemed to be "overcrowding," and in those parts of the town where the authorities have removed portions of the buildings in the old closes and have opened up small air-spaces, the sanitary condition of the inhabitants is by no means bad.

We next visited a block of new artisans' dwellings in Drygate. These so closely resembled the dwellings of a similar kind in London, which have been described in these columns, that it would be useless to detain our readers with what would be little more than a repetition of previous descriptions. We visited one house, consisting of two rooms and a scullery, the rent of which was £9 19*s.* 8*d.* per annum. By keeping the rent below £10, the occupier is saved a tax of 14*s.* 6*d.* Waterclosets, water-supply, and gas on the stairs are included in this rental. The rent paid is considerably lower than what would be paid for similar accommodation in London. Even in Peabody's buildings, which rest on a charitable basis, the rent for such accommodation would hardly be less than 4*s.* 6*d.* per week, or nearly £12 per annum; while in the dwellings of the Improved Industrial Dwellings Company probably a rental of £17 would be demanded. For one apartment and a scullery the rental in the Glasgow dwellings was £6 per annum. With these low rentals it is hardly to be wondered at that the dwellings have not been a financial success; for, while the returns are lower, the value of the areas upon which they are built is probably as high as in London.

Our next visit was to a model lodging-house which was built some years since by the municipal authorities, and which has paid the very handsome average dividend of 6 per cent. since its establishment. We were very pleased with the arrangements of this house, which seemed to us to approach very nearly to perfection. It affords accommodation for 228 male lodgers, who pay sums of 3*d.*, 4½*d.*, and 6*d.* per night. Sunday is counted as a *dies non,* and no rent is charged, so that the weekly payments are 1*s.* 6*d.*, 2*s.* 3*d.*, and 3*s.* All rent is paid in advance, and if a lodger persistently misconducts himself he is dismissed. The house is divided into day-rooms and sleeping apartments. The day-rooms consist of a common room for dining, reading, writing, and smoking, and a kitchen in which is a capital hot-plate, always heated, cooking utensils, and salt, the use of which is free to the lodgers. They are, of course, their own cooks, and at the time of our visit some of the inmates were boiling coffee, or cooking their evening meal. In the common room there are a series of lockers, keys for which may be obtained by paying a small deposit. In addition there is a lavatory and bath-room where, on payment of a penny, a hot bath may be obtained. The superintendent keeps a small shop, and is allowed to sell bread, butter, sugar, condiments, and other little things, for the benefit of the lodgers and himself. Those who pay the higher prices of 4½*d.* and 6*d.* a night, are provided with separate day-room, kitchen, and reading-room. The sleeping apartments are quite separate, and are kept locked except between the hours of 8 P.M. and 8 A.M. The sleeping-bunks are exactly like those on board a ship, only that the arrangement is much better, inasmuch as every lodger has a separate cabin. The beds are placed one above the other, in a double tier, but so arranged that the occupant of one has his cabin to the right, while the other has his cabin to the left. This arrangement, which permits of privacy without sacrifice of space, struck us as being in the highest degree ingenious. The divisions between the cabins are about six feet high, not running to the roof, and the general arrangement resembles that found in the public baths of London. The ventilation of the sleeping-berths is excellent, and the linen is changed once a fortnight. In short, the accommodation is fully equal in all essentials to that provided for second-class passengers in mail steamers, and much better than that of the officers and gentlemen who constitute the gun-room mess in Her Majesty's navy. These cabins contain a seat and clothes-pegs, and in some of them there is room for a clothes-box. Chamber utensils are, very wisely, not provided, but on every floor there is ample accommodation in the way of waterclosets and urinals. The division between the cabins and the framework of the beds is made in many cases of corrugated iron, and in this way the annoyance from vermin is minimised. The lodgers were stated to be a very tidy class of people, and many of them had lived in the house almost continuously from its erection. We should be glad to see the establishment of such houses in London, and we commend this Glasgow lodging-house to the attention of those who are interested in the welfare of the working classes. We much regretted that the time at our disposal did not permit of our visiting the cheap dining-rooms which are to be found in Glasgow, and by the establishment of which the original promulgator is said to have amassed a handsome fortune, although he provided ample dinners of meat and pudding, at once savoury, wholesome, and nutritious, for the modest sum of 4½*d.* Thus it will be seen that a single man living in a lodging-house and taking advantage of the cheap dining-rooms, might, if he chose, live in considerable comfort for a shilling a day, while those who lodged and boarded him would each get their profit. This seems startling, but is nevertheless a fact, and one is led to reflect how many of the hardships of the poor are due not so much to want as to mismanagement.

Having given samples of the condition of the poor of Glasgow under the old and new conditions, it remains for us to state briefly what has been done. The Glasgow Improvement Act was obtained in 1866, and the powers which it gave are very similar to the powers conferred by the Artisans' Dwelling Act of the past session. The trustees, who are members of the Town Council, have already purchased property to the amount of £1,400,000, which is being gradually demolished. In the matter of reconstruction the trustees limit themselves almost entirely to the formation of new streets (of which forty are projected) and open spaces. They then sell the surplus land and leave the building of houses almost entirely to private enterprise. The new houses, however, have to be built on a plan strictly in accordance with the police regulations. According to Baillie Morrison, the number of persons who have been displaced by the Glasgow improvements is 20,745, while house accommodation has been sanctioned or erected within the municipal boundaries for 162,625. No single case of hardship resulting from displacement has come under the notice of the authorities. The expense of these improvements to the ratepayers is estimated as less than the value of the ground thrown into new streets, including the expense of formation and causewaying the same.

There is good reason to believe, and indeed there are figures to show, that in the areas which have already been "improved" the death-rate from fever has greatly decreased, although perhaps it is too soon to draw conclusions from the health statistics. The effect upon crime, however, seems undoubted. Thus, in 1867, 10,899 crimes were reported to the police of Glasgow, while only 2975 persons were actually convicted. In 1873 there were only 7869 crimes reported to the police and 3526 convictions, notwithstanding that the city population had increased by nearly 58,000. Thus it appears that the demolition of the old "closes" and hiding-places has made the commission of crime more difficult and its detection more easy. It would perhaps be rash to draw any other conclusions from these figures.

The city of St. Mungo has chosen for its motto "Let Glasgow flourish"; and there can be little doubt that while its authorities show such enterprise and wisdom in providing water, air, lodging, and food for its inhabitants, it will continue to flourish in the future as it has deservedly done in the past.

Our thanks are due to Mr. A. B. M'Donald, C.E., for much attention shown to us during our visit to Glasgow.

THE WORK OF THE LOCAL GOVERNMENT BOARD.

THE Fourth Annual Report of the Local Government Board, which has just been issued, forms a bulky volume of 532 pages, and is devoted for the most part to the general duties performed by the Board during the year 1874, comprising the administration of the laws relating to Poor-law relief, of the Local Government and Sanitary Acts, and of the laws relating to Public Health. The second section of the Report, which more particularly concerns our readers, contains a record of the appointments made under the terms of the Public Health Act of 1872. From this, it appears that up to the close of last year a total of 727 medical officers of health had been appointed—360 by rural, 287 by urban, and 80 by combined authorities. These figures do not, however, show the whole number of appointments which have been made, those being excluded who have not yet availed themselves of the Parliamentary grant. There are now, however, very few instances in which either urban or rural authorities have failed to appoint a medical officer of health and an inspector of nuisances. The moiety of salaries of medical officers granted by the State amounted to £26,870, and that of the inspectors of nuisances to £23,187. The total amount of loans to sanitary authorities sanctioned since the passing of the Public Health Act, 1848, is more than three and a half millions. Twenty new urban districts have been formed during the past year, and the temporary orders constituting the 46 port sanitary authorities have been continued for a further period, it not being considered desirable at present to confirm them, "as the arrangements made have not been tested by any serious outbreak of disease." The order as to the port of Liverpool, where the circumstances were exceptional, was confirmed by Parliament during the last session. A total of forty-seven provincial orders issued by the Board were confirmed by Parliament, thirty-three private Bills conferring powers upon sanitary authorities have been deposited with the Board during the year, comprising, among other matters, the construction or extension of waterworks, gasworks, works of sewerage, and street improvements, the establishment of joint sewerage boards, &c. A detailed account is given of the provisions of the Sanitary Law Amendment Act, 1874, which need not be recapitulated here, as it is already superseded by the Consolidation Act of last session. A brief reference is also made to the operation of the Alkali Acts. The passing of the Sale of Food and Drugs Act likewise renders any remarks as to the Adulteration of Food Acts superfluous. The report itself concludes with a brief reference to the Metropolis Water Act, 1871, and to the special Reports of Mr. Simon, three of which have been already noticed in THE LANCET, and the fourth, on Cholera, has not yet been published.

The appendices include a very long Report by Mr. Nettleship on Ophthalmia in Metropolitan Pauper Schools, on the Boarding-out of Pauper Children, on the results of Workhouse School Education in Country Unions, and on Vaccination, all of which require a separate notice. From a return relating to paid officers it appears that during the past year there were in provincial unions ten forced resignations, and one dismissal in the case of medical officers of workhouses, and two forced resignations among those connected with the metropolitan establishments.

SCIENTIFIC GRANTS OF THE BRITISH MEDICAL ASSOCIATION.

The Scientific Grants Committee of the British Medical Association have this year received £300 for allotment amongst those who desire assistance in original researches in medical and the allied sciences. The following grants have already been made, and the Committee are prepared to allot the balance of £170. Applications, which must not be made later than the 29th December next, should be sent in at as early a date as possible to the General Secretary of the Association, 36, Great Queen-street, W.C.:—Drs. Braidswood and Vacher, on the Life History of Contagion, £25; Professor Rutherford, Researches on Biliary Secretion, £20; Dr. Crichton Browne, on the Antagonism of Medicines, £10; Dr. M'Kendrick and Professor Dewar, on the Physiological Action of Chinoline and Pyridine Compounds, £25; Dr. Mahomed, the Pathology of Albuminuria, £15; Dr. Munro, Cupar, Fife, an Antidote for Chloroform, £3; Dr. Caton, on the Electric Currents of the Brain, £15; Dr. Fothergill, the Effect of certain Agents on the Circulation, £10; Dr. Spencer Clifton, the Action of Uranium Salts on Diabetes, £10.

In addition to the scientific grants, Mr. Samuel Wood, of Shrewsbury, has generously presented £25, to be given for the best essay on Pyæmia, and there is also the Hastings prize medal of 20 guineas offered for the best paper on Diphtheria, its Pathology, Diagnosis, and Treatment.

"Audi alteram partem."

EPSOM COLLEGE.

To the Editor of The Lancet.

Sir,—On Thursday last we visited for the first time Epsom College, and, as our presence there was wholly unexpected, our testimony on the general as well as special aspects of that establishment, seeing that we possess no connexion with it, may be relied on. We are, however, anxious that the public, as well as the Governor who writes to you in your last number, should know the truth respecting "the badness of the water and the food."

As staff officers in H.M. Indian army, we have had considerable experience in sanitary matters, as well as in questions of food. We can therefore unhesitatingly assure the Governor that these complaints from the Epsom boys are wholly groundless; purer water and more wholesome food cannot be obtained than we partook of in the College. All the drinking-water is filtered through a large Lipscombe.

As our visit was more than an ordinary one, we will, with your sanction, do more than reply to the letter of the Governor.

We arrived at the College during school hours, and, being accompanied by one of the officials, we entered the school and class-rooms, and were very much gratified at finding the atmosphere in all perfectly free from odour, due to the free ventilation and open windows. School work was not interrupted. We were very much impressed with the healthy aspect of the boys, numbering in all upwards of 200. Somewhat later in the day we saw football and other games in full force; these enjoyed in such an open district in part explained the healthful appearance of the boys.

The baths and gymnasium, too, we found in excellent order, as well also the racket-court; and a more charming cricket-ground we have never seen. Whilst inspecting these the dinner-bell sounded—the first, which is served at 1 p.m., to which we were invited. At the upper table several of the masters partake of luncheon, whilst at each table a master presides. The dinner consisted of beef (ribs and loins) and legs of mutton and plum pudding. The potatoes were small and rather waxy, and the beer somewhat sour. With these exceptions everything was of first-rate quality, and there was no stint to quantity. Our impression is that more animal food was eaten by most of the boys than is good for them.

After dinner we inspected the kitchens, and found everything clean and well ordered. Benham's stove was in full operation, the second dinner being cooked. The potatoes which were being steamed were of a better description than those of which we had partaken at the early dinner; indeed we were told that the stock was from a fresh contract.

Passing up-stairs we were shown the bedrooms, and more commodious and cleaner we had never seen.

In the infirmary—suites of rooms adjoining the pensioners', and as far as possible from the school,—we found five boys, four eating mutton-chops, and one enjoying a bason of beef-tea. These youths we were told had scarlet fever. Up a distant flight of stairs two other boys, who looked very well, were said to have had chicken-pox.

In conclusion, we cannot withhold our highest admiration and approval of this well-conducted and well-ordered public school.

Your obedient servants,
St. James's-square, W., Oct. 1875. Two Staff Officers.

To the Editor of The Lancet.

Sir,—I was glad to see the letter in The Lancet, signed "A Governor of the Medical Benevolent College," directing attention to the fact that several boys are now suffering from scarlet fever. It is quite true that this disease made its appearance at the College during last term, and as two or three boys were taken ill less than a fortnight after the vacation, I think we can come to no other conclusion than that necessary means were neglected to stamp out infection. My son is one of the victims, and has been seriously ill. An attack of scarlet fever must at all times be a source of great anxiety; in this case it is something more, to both parents and pupils. The pupil suffers the loss of the term, for which the parent has to pay. And as soon as the invalid is well enough, of course his parent must take him away. The question arises, Where to? I have other sons attending schools, one at Merchant Taylors'. A convalescent from scarlet fever must not come to my house. I shall have the additional expense and trouble of finding a home for my boy till Christmas.

I think two alterations are required at Epsom College. I am under the impression that the diet allowed is not equal to that of private establishments, and I think the boys should have more exercise out of the College grounds.

I am, Sir, your obedient servant,
James Collyer, L.R.C.P. Lond., &c.
Oak House, Enfield, Oct. 26th, 1875.

FATAL OUTBREAK OF TYPHOID FEVER IN UPPINGHAM SCHOOL.

To the Editor of The Lancet.

Sir,—Will you allow me to draw your attention to the fatal outbreak of typhoid fever in Uppingham School, and to certain facts connected therewith. A fortnight ago yesterday, a relative of mine showed me a letter he had just received from Uppingham, telling him that his eldest son was suffering from a mild form of low fever, which was epidemic there, and which had been said to be due to atmospheric influences, from the excessive wet succeeding the drought in the Midland Counties, and this was given on the authority of a London physician. The parents were told not to alarm themselves, but that if any bad symptoms did make their appearance, they would be informed. I, naturally, translated it as typhoid fever, in spite of the eminent authority, and was asked to go down at once. I left by the next train from Euston-square, and on my arrival at Uppingham called on the master of the lower school, where my little friend was. I found him very reticent, repeating the above opinion, and adding more explicitly that it was a malarious sort of fever. I was introduced to the head master, who gave me permission to visit the boy. He had been removed to the Sanatorium, a small house a little distance off. I found him in a small room with another boy. He was in the second week of typhoid fever, with a temperature of over 105° F. at 4 P.M. I had asked to have the ordinary medical attendant to accompany me, but heard he was out visiting; and I had to return to town that night. I did, however, see him before my return, and asked him why he allowed such rubbish to be written, but he disclaimed all responsibility in the matter. I came back to London, sent down the boy's mother, and I am glad to say he is going on favourably; but there have been several deaths, and it was not till case after case occurred, and perhaps owing to the ill-health of the master himself, that the lower school was at last dismissed. The upper school is still going on. I am told that at the outbreak of the fever the head master assembled the boys and told them that there was no cause for alarm, and that boys who wrote home and got themselves removed would be considered cowards and deserters.

I complain of the school authorities for not telling parents when the fever first broke out, for not telling them even when the children first showed signs of disease, for studiously shutting their eyes to the real nature of the disease, for doing nothing to improve their sanitary arrangements, and for keeping boys in places which were mere pesthouses, as I hear they have been condemned by the medical officer of health.

I enclose my card.

I am, Sir, yours obediently,

October 26th, 1875. MEDICUS.

Obituary.

DUCHENNE (DE BOULOGNE).

(From our Paris Correspondent.)

DUCHENNE (DE BOULOGNE), whose death you noticed in your last issue, was born in 1806, and consequently died at the age of about seventy. After having graduated he began practice in Boulogne-sur-Mer, his native place, but soon found this field too narrow for his restless and inventive mind, and for the experiments which he was already conducting, and so he left for Paris, where, during thirty-three years, he led a life of incessant scientific labour.

In 1847 he presented his first memoir to the Academy of Sciences, and up to within a month previous to his death he continued to publish, either in the Transactions of the two Academies or in the *Archives de Médecine*, the results of his experiments and observations. Amongst the most important of his researches are those on the muscular system; the isolated action and synergy of muscles. His studies on the muscles of the face, and on their office in the mechanism and expression of the human visage, are remarkable, and are familiar in France to artists as well as to medical men. But it was especially in his researches on the nervous centres, on the various forms of paralysis, on congenital or developed deformities, that his great qualities of observation manifested themselves. His name will ever be coupled with the history of progressive muscular atrophy, locomotor ataxy (to which Trousseau proposed that the name of "Duchenne's disease" should be given), glosso-labio-laryngeal paralysis, and, generally, the microscopical anatomy and pathology of the nervous system. His right of priority to the description of certain forms of nervous diseases has been disputed, and with justice; as, for instance, in the case of locomotor ataxy, where Romberg certainly had the precedence. But at the same time, it may be stated that all Duchenne's descriptions and discoveries were original, and the result of his own labours. The writings of Romberg and other foreign *savants* were at the time unknown in France, not only to Duchenne, but even to the best men having a knowledge of foreign languages.

A great many of his researches were carried on by means of electricity, and in turn they threw light on the uses of this powerful agent, and to Duchenne will redound the honour of having methodically applied electricity to physiological and pathological investigations, and of having scientifically used it for the treatment of disease.

His features were familiar to all who visited habitually the wards of the Paris hospitals. Every morning Duchenne was to be seen in one or other of the hospitals, studying cases, examining specimens, drawing his photographs of microscopical appearances, in which he was extraordinarily skilful. For a long time Duchenne's invariable presence in the wards, his incessant moving about, his ardent interrogation of patients, caused him to be looked upon with a somewhat suspicious and anxious eye by many of the hospital physicians. But his consummate experience of disease, his wonderful keenness and ability in making out a diagnosis in cases of paralysis, the sincerity and earnestness of his manner, the honesty of his proceedings, the authority which he gained by the publication of his original researches, the services which he rendered daily in the wards of the hospitals, brought him the esteem and appreciation of all, and made him a welcome guest everywhere.

He was no orator, and could never have given a lecture on any subject, but he was wonderful at the patient's bedside. Dexterous and nimble in handling his patient, sharp and sensible in his questioning, most striking in the way he got up his data, made out the disease, and gave practical demonstrations of the surety of his diagnosis. Amongst the various instances of this last quality which were related in the hospitals about Duchenne was the fact of his taking patients accounted to be paraplegic out of their beds, and of causing a man to get on their shoulders without their giving way in the slightest.

His patience was extraordinary. He would pursue the investigation of a case for years, never losing sight of it, and following the patient in his peregrinations from hospital to hospital and from house to house, often affording help and means of subsistence.

It may be said of Duchenne that under many adverse circumstances—the suspicions of *confrères*, the disputes as to priority, the difficulty of finding a field of study and experiment, as he had no hospital appointment—his reputation has come out clear and bright, as an honest, hard-working, acute, and ingenious observer, an original discoverer, a skilful professional man, and a kind-hearted, benevolent gentleman.

His various writings have been gathered, and are included in the following important works:—"Traité de l'Electrisation Localisée" (third edition); "Le Mécanisme de la Physionomie Humaine"; "La Physiologie des Mouvements Démontrée à l'aide de l'Expérimentation Electrique"; "Anatomie du Système Nerveux"; "Orthopédie Physiologique."

ROYAL COLLEGE OF PHYSICIANS.

AT a meeting of the College of Physicians, on Thursday afternoon, the Fellows were informed that the Gulstonian lectures for the year 1876 would be delivered by Dr. A. B. Shepherd, the Lumleian by Dr. Habershon, and the Croonian by Dr. Dickinson. After the formal admission of the new fellows recently made, the College elected as members after examination, Dr. D. T. Leech and Dr. G. C. Herman, and Dr. R. Hassall under a special bye-law applicable to extra-licentiates. A communication was read from the Foreign Office containing an account of the plague in Mesopotamia, from Surgeon-Major Colville. The epidemic followed the inundation of the country from the overflowing of the Euphrates, and the disease was probably of a dysenteric nature. A letter was read from Mr. Iliff, of Epsom, offering to present the College with a veritable pair of "Perkins' Patent Metallic Tractors," so much in vogue many years since, and used by "quacks." The thanks of the College were ordered to be offered to Mr. Iliff for his present, which was of course accepted. A second gift of certain seeds used in Borneo for the treatment of fevers was received from a gentleman in that place, with a view to their examination by the College. The donor expressed his wish to send supplies of other medicinal substances in use in Borneo. The Registrar was desired to ask for supplies of these substances. A letter was read from the President of the College of Surgeons, in which it was proposed to hold a conference of the several representatives of the bodies co-operating in the promotion of a Conjoint Scheme, and asking if the College would be willing to send two representatives. Probably, as we understand, among the questions to be discussed would be the admission of the Society of Apothecaries to participate in the Conjoint Scheme, and the advisability of modifying in some particular the scheme as at present constituted. The College accepted the invitation, and deputed the President and Registrar to represent the College in the matter.

Medical News.

Royal College of Surgeons of England. — At the last meeting of the Council the following Member was elected a Fellow of the College :—

Bennett, Robert Blacker, Cleckheaton, Yorks.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Oct. 21st :—

Blake, George Farncombe, Old-square, Birmingham.
Parker, Alfred Charles, Worthington, Leicestershire.
Thayer, L. Orton, Mildmay-park.
Tyrrell, Frederick, Harlington, Middlesex.

The following gentlemen passed the Primary Professional Examination on the same day :—

Cordley Bradford, Queen's College, Birmingham ; Arthur Randall Davis and John Wallis Barron Mason, Middlesex Hospital ; James Warner, London Hospital.

Dublin Hospital Sunday this year will take place on the 14th proximo.

Dr. Joseph Wickham, of Penrith, has been placed on the Commission of the Peace for the county of Cumberland.

At the last meeting of the Council of the Irish Medical Association, Dr. Nolan, of Gort, Fellow of the Royal College of Surgeons, was unanimously elected Vice-President of the Association for Connaught.

Dr. Frankland, F.R.S., reports that the proportion of organic impurity in all the river waters supplied to the Metropolis during the month of September was much less than that observed in August.

At the last meeting of the Guild of St. Luke, held at 68, Mortimer-street, on the 20th inst., Mr. Boyd B. Joll was elected Secretary, vice J. Thompson Hayne. For information respecting the Guild address to the present Secretary, at University College, London.

The Royal Commission to inquire into the practice of subjecting live animals to experiments for scientific purposes met at 13, Delahay-street, on Saturday. There were present—Viscount Cardwell, Lord Winmarleigh, Mr. W. E. Forster, Sir John B. Karslake, Mr. T. H. Huxley, Mr. J. Eric Erichsen, Mr. R. H. Hutton, and the Secretary, Mr. N. Baker.

Medical Appointments.

Anderson, J. W., M.D., F.F.P. & S. Glas., has been appointed an Examining Medical Officer to the Hospital for Incurables at Broomhill, Kirkintilloch.

Bailey, J. B., M.D., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the sixth District of the Bath Union; Officer of Health to the Sanitary Authority; Surgeon to the Bluecoat School, the Foresters' and Barrett's Clubs.

Barton, J. K., M.D., F.R.C.S.I., has been appointed Visiting Surgeon to the Convalescent Home, Stillorgan, vice Barker, appointed Assistant-Surgeon to University College Hospital, London.

Bellmont, J. T., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the Parish of Dalkeith, Edinburghshire, vice Jefferiss, deceased.

Caldwell, S., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Crossbane Dispensary District of the Bailieborough Union, Co. Cavan, vice Atkin, resigned.

Clayton, R., L.R.C.P.L., M.R.C.S.E., Medical Officer for the Accrington District of the Haslingden Union, has been reappointed also Public Vaccinator.

Durrant, C. M., M.D., F.R.C.P.L., has been appointed Visiting Physician to Lunatic Asylums in the Borough of Ipswich.

Foster, B. W., M.D., F.R.C.P.L., has been appointed Consulting Physician to the Birmingham and Midland Counties Ear and Throat Infirmary, vice Fleming, deceased.

Fussell, E. F., M.B., M.R.C.P.L., has been appointed a Physician to the Sussex County Hospital, Brighton, vice Moon, resigned.

Greaves. E., L.R.C.P.Ed., M.R.C.S.E., has been reappointed Medical Officer and Public Vaccinator for the Weldon District of the Oundle Union.

Harrison, J. A., M.D., has been appointed Medical Officer of Health for the Haslingden Rural Sanitary District for six months: £100 per ann.

Hollis, W. A., M.D., M.R.C.P.L., has been appointed an Assistant-Physician to the Sussex County Hospital, Brighton, vice Fussell.

Hyatt, J. T., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the 1st Division of No. 4 District of the Shepton-Mallet Union, vice Macdonald, resigned : £18 per annum and fees.

Ireland, A. J., M.D., L.R.C.P.Ed., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Ardrahan Dispensary District of the Gort Union, Co. Galway, vice Nally, appointed to the Kinvarra Dispensary District.

Jones, M., M.R.C.S.E., has been appointed Medical Officer to the Westmoreland Society's Schools, Norwood-lane, vice Mercer, deceased.

Kinsey, R. H., M.R.C.S.E., has been appointed Medical Officer to the County Prison, Bedford, vice Couchman, resigned : £130 per annum.

Morriss, S., L.R.C.S.I., L.M., has been appointed House-Surgeon to the Stanley Hospital, Liverpool, vice Bark, resigned.

Parkinson, C. H. W., M.R.C.S.E., has been appointed Medical Officer to the Wimborne Police, vice C. B. Parkinson, M.R.C.S.E., deceased.

Power, J., L.R.C.P.Ed., L.R.C.S.I., L.M., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Borrisoleigh Dispensary District of the Thurles Union, Co. Tipperary, vice Quinlan, resigned.

Pritchard, R. C., L.F.P. & S. Glas., L.M., has been appointed Medical Officer of Health for the Wigton Urban Sanitary District: £40 for one year.

Rossiter, D., M.R.C.S.E., Medical Officer for the Leverton District of the East Retford Union, has been reappointed also Public Vaccinator.

Smith, P. B., M.B., C.M., has been appointed Chloroformist to the Royal Infirmary, Aberdeen.

Somerville, T. A., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Wilmslow District of the Altrincham Union, Cheshire, vice Bower, deceased.

Stewart, D. P., M.R.C.S.E., has been appointed a Visiting Medical Officer to the Hospital for Incurables at Broomhill, Kirkintilloch.

Sutcliff, E., M.D., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Peters-Marland District of the Torrington Union, vice Pattinson, resigned.

Sykes, W., M.R.C.S.E., L.R.C.P.Ed., has been appointed House-Surgeon to the Doncaster General Infirmary and Dispensary, vice Wallis, resigned.

Wallace, A., M.B., C.M., has been appointed an Examining Medical Officer to the Hospital for Incurables at Broomhill, Kirkintilloch.

Warren, A., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the No. 8, or Wooburn District of the Wycombe Union, Bucks, vice Hayden, resigned.

Wells, E., M.D., F.R.C.P.L., has been appointed Visitor of Houses licensed for the reception of Lunatics in the County of Berks.

White, R., M.B., L.R.C.S.I., has been appointed a Medical Officer for the Carrignavar Dispensary District of the Cork Union.

Whitelaw, W., M.D., F.F.P. & S. Glas., has been appointed a Visiting Medical Officer to the Hospital for Incurables at Broomhill, Kirkintilloch.

Births, Marriages, and Deaths.

BIRTHS.

Brend.—On the 11th inst., at Argyll-road, Kensington, the wife of Wm. Brend, M.R.C.S.E., of a daughter.

Butler.—On the 13th inst., at Ormonde House, Guildford, the wife of T. M. Butler, M.R.C.S.E., of a son.

Clarke.—On the 17th inst., at Mansfield-street, Cavendish-square, the wife of Wm. Fairlie Clarke, F.R.C.S.E., of a son.

Cribb.—On the 21st inst., at Bishop-Stortford, the wife of Henry Cribb, L.R.C.P.L., of a daughter.

Hayward.—On the 23rd inst., at Hillside, Ealing, the wife of H. Howard Hayward, M.R.C.S.E., of a daughter.

Rickards.—On the 21st inst., at Cavendish-place, the wife of Walter Rickards, M.D., of a son.

Winkfield.—On the 15th inst., at Forest Lodge, Shirley, the wife of W. B. Winkfield, L.R.C.P.Ed., of a daughter.

MARRIAGES.

Hamilton—Staveley.—On the 20th inst., at the Reformed Presbyterian Church, Ballymoney, Alex. Macleod Staveley Hamilton, M.D., to Jane Adams, daughter of the Rev. A. M'L. Staveley.

King—Wickham.—On the 19th inst., at St. Mark's, Portobello, Thomas Radford King, M.D., to Agnes Jane, daughter of the late Benjamin Wickham, Esq.

Owen—Greenwell.—On the 20th inst., at St. George's Church, Poynton, Cheshire, S. Holgate Owen, M.D. (eldest son of Henry Owen, Esq., of Manchester), to Catharine Jane, eldest daughter of E. C. Greenwell, Esq., of Poynton.

DEATHS.

Atkins.—On the 19th inst., at Hadleigh, Suffolk, Alfred W. G. Atkins, L.R.C.P.Ed.

Baxter.—On the 16th inst., at Emsworth, Wm. R. Baxter, L.K.Q.C.P.I.

Crisp.—On the 3rd inst., Henry Crisp, M.B., Staff Surgeon-Major Army, of St. Martin's Chambers, Charing-cross, aged 50.

Dwyer.—On the 13th inst., at Tuam, James Dwyer, M.R.C.S.E., aged 58.

Miller.—On the 19th inst., at Denmark-hill, Benj. Miller, M.R.C.S.E., aged 51.

Plant.—On the 25th ult., at Plantation, Monkstown, Co. Dublin, Wm Plant, M.D., F.R.C.S.I., J.P., in his 85th year.

Wrangham.—On the 21st inst., at Wragby, Lincolnshire, J. D. Wrangham, M.D., aged 59.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

Sale of a Hospital under Protest.

At the recent sale of the Vernon Hill Estate, in Hampshire, the property of the late Sir Arthur Helps, the large farms and clay-works were bought in; but some of the other lots realised good prices. Among the lots sold was a building known as the Royal Albert Infirmary, which was bought by a resident at Botley for £1000. This hospital was erected at a cost of £3000, raised by public subscription, on a site given by Sir Arthur. When the building was put up for sale, a protest was handed to the auctioneer on behalf of the Infirmary Committee, and read; but, under the advice of the solicitor for the sale, the auctioneer proceeded to dispose of the building with the above-mentioned result. The first stone of this building, which was intended for an infirmary, although it was never used for that purpose, was laid by Prince Leopold in 1865, in the presence of other members of the Royal Family. The sale of this charitable institution has excited considerable local interest, as there was a strong wish that the building might be obtained for the purpose of providing an addition to the Grammar School of Bishops Waltham. If, as stated above, the site was presented by Sir Arthur Helps, and the building was erected by public subscription, it is not easy to comprehend how the ownership of the land and of the infirmary should have reverted to the representatives of Sir Arthur Helps. Whatever cause militated against the building being used as a hospital, the right of the original owner of the land to step in and reclaim it, together with the buildings erected thereon, appears to require further explanation.

Mr. C. Clapham.—It is hardly necessary to publish the letter.

Sea-sickness.

To the Editor of The Lancet.

Sir,—As the above subject is occupying attention, I venture to send you the result of an experiment I tried upon myself when I last crossed the Channel. The weather was boisterous and the sea very rough. Being a bad sailor I expected to have a miserable passage. Directly the steamer left the harbour we shipped a heavy sea, which completely deluged the deck, and the vessel pitched in such a manner that in a very short time I think I was the only passenger, or almost the only one on board, who was not dreadfully ill. It occurred to my mind that if I could succeed in fixing the diaphragm and muscles of respiration for regular periods, so as to prevent the sudden irregularities that take place in their action, more particularly as the vessel falls into the trough of the sea, I might modify, reduce, or prevent the discomforts of sea-sickness. How to accomplish this was at first a puzzle. I suddenly bethought me of *music*, and I commenced to hum a tune, more mentally than audibly, with regular and rather prolonged cadences. To my intense gratification the experiment answered admirably, and so long as I continued it no nausea occurred. If I ceased only for a few moments, the sensation (which can only be sufficiently appreciated by those who suffer) immediately presented itself. The result, however, was that for the first time in my life I was landed at Folkestone, after a very rough passage, feeling none the worse for my voyage. Now, I do not make this suggestion with the idea that passengers will be induced to form themselves into a temporary choral society, or that it could be carried out during a long voyage; but if the idea be a sound one, some relief might probably be obtained by a tight flannel bandage firmly bound round the waist, after the fashion of a rib-bandage in case of fractured ribs. If sea-sickness is the result of *irregular* pressure of blood on the brain, my plan will at least control it in a measure; for we know that the blood-supply to the brain is influenced by respiration. If it arises from a kindred cause to that which produces nausea when a person rides in a carriage with his back to the horses, I am at a loss for an explanation. In the latter case, however, it must not be forgotten that the retina is performing its function in *reversed order*, and that every object is receding instead of advancing. I do not know whether the same distress is felt in absolute darkness, or in a perfectly closed conveyance, or by people deprived of sight.

I remain, Sir, yours &c.,

Hampstead, Oct. 18th, 1875. H. Cooper Rose, M.D.

Quackery in Colorado.

We have received a letter from Denver, a thriving town at the base of the Rocky Mountains, enclosing a quack advertisement from the local paper, and asking our opinion of the same. There is no such person in London as Sir William Paget. The advertisement is an impudent lie, and the concoctor ought to be punished by the authorities of Denver.

Questions of Taste.

Probably no one who has not been personally concerned in submitting a question of taste to some corporate body or bench of magistrates can form any adequate idea of the difficulties to be encountered. The other day we were called upon to sympathise with the endeavours of a public analyst to convince a Common Councilman that a particular water-supply was poisonous, in face of the Councillor's own perception that the fluid was "clear, sparkling, cool, and refreshing." Our commiseration is now requested for a cheesemonger of Bilston, who has been convicted of exposing for sale cheese "unfit for human consumption," simply because the assembled justices did not happen to appreciate some fragments of the "ripe" delicacy, though handed to their worships in the most appropriate fashion on suitable pieces of bread. We cannot help thinking there was some mismanagement in the conduct of this case. The presentation of the cheese was all very well; but it does not appear to have been explained that, instead of being simply "decomposed"—which seems to have been curiously admitted,—the cheese in question had been submitted by nature to what may be described as a sort of "antiseptic treatment," and that, in point of fact, the mould was that pretty fungus, *Aspergillus glaucus*, or some cryptogamic growth, perfectly innocuous, and, to some palates, nice. This was a great omission; and seeing that the magistrates of Bilston were not properly instructed by the scientific witnesses, it is difficult to condemn them for acting on their own judgments. The taste which prefers fungous cheese, like that which affects a state of tolerably advanced decomposition as the condition of game, is wholly acquired. Except under compulsion, a simple and natural perception would probably choose food in its original purity. The taste that appreciates clear and apparently fresh water, oblivious of the causes from which these qualities may sometimes chance to spring, is simply ignorant, and may be excused—except for its stupidity.

MacGregor.—Parkes; Wilson. Letts's Diaries contain such information.

"Noblesse Oblige."

To the Editor of The Lancet.

Sir,—I desire to draw your attention to a statement of the treatment I met with recently from the authorities of the North Cambs Hospital.

On the 2nd inst. I was summoned by telegram to my father, about twenty miles from here, and who had practised for half a century a few miles from Wisbeach. I found him suffering acutely with fractured humerus and injury to the elbow. I endeavoured to procure an ordinary angular splint from the surgeon who had visited him. He, however, had not one, but suggested that I might obtain the loan of one from the North Cambs Hospital. I introduced myself to the house-surgeon (an elderly person, who had previously been in private practice), and preferred my request, which, to my surprise, he refused, alleging as an excuse "that no instrument or appliance was allowed to be taken out of the hospital." I did the best I could for the patient, extemporising a millboard splint, and, having to return to my own practice the same day, I was compelled to undertake the journey some days later, provided with the necessary appliance.

I wrote to the Chairman of the Hospital Committee, suggesting that if such a rule were in existence, I thought it would be desirable to modify it to meet future cases, and at the same time expressing my surprise at the unprofessional treatment I had met with. The rev. chairman replied in a most uncourteous spirit, that he "had laid the matter before the Committee," that they considered the house-surgeon had "acted perfectly in accordance with the rule," and that they "did not think it advisable to alter the rule."

To refuse aid to a medical *confrère* on an emergency like the above, and particularly to alleviate the sufferings of another medical brother, seems to me to call for severe animadversion. At no other institution in the kingdom, I believe, would similar behaviour be manifested. In this neighbourhood, from the Norfolk and Norwich Hospital aid in the shape either of instruments or surgical appliances is always most readily granted, and I doubt not from every other like institution. I trust that by your publicly drawing attention to the case, the authorities of the North Cambs Hospital may be induced to act in a similar spirit.

I remain, Sir, yours truly,

Beccles, October, 1875. R. I. Metcalfe.

P.S.—Since writing the above, a friend writes me:—"At football at Richmond the other day, B., one of the players, had his leg broken. N. sent off his dog-cart to the infirmary for splints &c., when *everything that could by any possibility be required was sent at once without demur.*"

*** We quite agree with our correspondent.—Ed. L.

The "Boarding-out" System.

The farmers of Cheshire appear to be wise in their generation. They have induced the Board of Guardians of Nantwich to hand over to them the pauper lads of the union, with a subsidy of 3*s.* 10*d.* a week per head. This method of recruiting the agricultural labour market, impoverished somewhat by the exertions of Mr. Arch and his colleagues, will, it is to be hoped, if perpetuated, be carried out with a view to the future interests of the lads as well as the pecuniary profit of the farmers. The "farming" of boys is rather a novel enterprise in England; but it need not, so far as we can see, be attended with anything but good to all concerned.

Medical Registration.

To the Editor of The Lancet.

Sir,—In 1869 a practitioner registers two legal qualifications; in 1872 he registers an additional qualification, on each occasion paying the usual fee. In 1875 he sends notice to the Office of change of residence, and then is informed that his additional qualification has never been entered in the printed Register. Can he sue the Registrar or the Council for breach of contract? What does the Council do with the fees? What practical benefit has resulted, or is likely to result, to the profession or the public from the scheme?

Yours &c.,

October, 1875. R. Rendle.

THE EUCALYPTUS GLOBULUS.

IT will be remembered that the cultivation of this tree was very strongly urged a short time since as a simple and safe way of robbing malarious soils of their injurious properties, and some practical illustrations were also adduced, in order to show what this tree was capable of effecting in this respect. Allowing for exaggeration, it is still, we think, very probable that the growth of these trees in damp and malarious localities would greatly tend to increase the salubrity of the soil. In suitable places the Eucalyptus globulus grows vigorously enough. It was introduced into the Cape by Sir Lowry Cole in 1828, and since that time it has been extensively cultivated and spread throughout the colony. The young plant is said to be tender and incapable of resisting a lower temperature than 27° F., and it is alleged that most of the trees planted by the Roman municipality perished from this cause. The tree does not branch out so much in a lateral as in a vertical direction, and the growth of the leaves is also similar, the edge, instead of the broad of the leaf, being presented. It is of very quick growth, and the roots are long and horizontal in direction. It will be obvious that these characters are very favourable to rapid absorption of water from the soil, and to the ventilation of the ground by the free admission of air through the leaves and branches.

W. W. F. is thanked for his courteous communication.

TYPHOID FEVER FROM AN UNEXPECTED SOURCE.

To the Editor of THE LANCET.

SIR,—All evidence bearing upon the possible origin of the poison of typhoid fever, or of any fresh source through which it might be disseminated, should, I think, be made public, so that it may receive confirmation, or be rejected by further evidence. The possible source to which I wish to draw attention was impressed recently upon my mind by the singular coincidence of two persons being attacked at the same time, who, living apart, yet attributed the cause to the same source. It will be seen also that both were affected at the same time, were attacked in about a week afterwards, and that they were the only cases which occurred in a considerable population, and within a radius of several miles.

A., a groom, called to see B., a coachman, at a stable (detached), half a mile distant from his own home. While they were sitting in the coachman's room above the stable, both became suddenly aware of a fearful stench in the room, sufficiently bad to compel them to get up, to rush to and to open the windows. The stench, it was afterwards seen, proceeded from an evacuation by a large Newfoundland dog, who was then ill with what was called by the veterinary surgeon "ordinary distemper." In about a week from this occurrence the men in their respective homes, and without having again seen each other, were simultaneously attacked with symptoms of typhoid fever, and in due course the rose spots appeared, and both passed through a severe form of the disease, the coachman at last succumbing to it. The dog also died, after having suffered from dysenteric diarrhœa, congestion of the lungs, liver, &c.

The post-mortem examination which was made of the dog revealed, according to the evidence of the veterinary surgeon, disease of the bowels and congestion of the lungs and liver, and these, he says, are the usual appearances in dogs who die of "distemper," and which almost every dog is supposed to have in some form or other before he is a year old.

It has been impossible to trace any other source than that mentioned for the attacks, and as no other cases have occurred since (several weeks having now intervened), and none previously for several years in the immediate neighbourhood, it seems reasonable to look upon the cause cited as that which produced the disease. Moreover, the men seemed continually impressed with the idea that the stench experienced had to do with their illness. Living also at least half a mile apart, and under different conditions, they had nothing in common. The coachman slept when attacked in his employer's house (not in the stable), as the members of the family were from home, and the groom at his own place.

If the disease known by the vague name "distemper" in the dog is capable at any time of so affecting a human being that he suffers afterwards from typhoid fever, it seems only reasonable to suppose that it must be a disease very nearly allied to, if not identical with, typhoid fever. The symptoms are alike, and both are diseases which chiefly affect the young. This much granted, and we have almost always ready at hand a most abundant source for the production and dissemination of typhoid poison, and a means whereby the homes of rich and poor, particularly of the former, may be invaded at any time. Again, in rural districts, where the water for drinking purposes is obtained from open wells, how easy it would be for one affected animal to contaminate the whole, and hence to cause a local epidemic of the fever.

I am, Sir, yours faithfully,

October, 1875. H. H.

Mr. E. D. Harmar, (Aboyne, Aberdeenshire.)—Moore's Manual of Family Medicine for India, with Medical Cabinet (Churchill, New Burlington-street) will meet our correspondent's requirements.

THE letter of *Dr. Dowse* shall not be forgotten.

Inquirer had better communicate with the gentleman who delivered the address.

Dr. Geo. Buchanan's address at Glasgow shall be published next week.

HYDROPHOBIA.

To the Editor of THE LANCET.

SIR,—Some years ago I read in the library of the Athenæum Club, in a book or periodical, an account of some experiments conducted for the purpose of ascertaining whether it were possible to produce hydrophobia in dogs by artificial means. I have since made repeated and wearisome attempts to find the passage, which I remember related to experiments upon *three* dogs, who were treated in some respects variously. Can you or any of your readers help me? I should feel greatly obliged if any gentleman would send the information direct to the address of "J. C., Athenæum Club, Pall-mall."

Your obedient servant,

Oct. 22nd, 1875. J. C.

INGUINAL HERNIA: NOVEL MODE OF REDUCTION.

THE *Lyon Médical* of October 17th, 1875, quotes an article of the *New York Medical Record* (July 24th, 1875) of Dr. Hadden. To reduce an inguinal hernia in a woman of forty-five, who refused kelotomy, the author narcotised the patient with chloroform, introduced his finger into the rectum, and gradually passed his hand as far as the colon. The hand was somewhat obstructed when it reached the promontory of the sacrum; but this obstacle being overcome, it travelled higher up. Dr. Hadden states that he then succeeded in feeling the congested intestine, and used gentle traction with the hand within the abdomen, whilst with the other he performed gentle taxis externally. The reduction was thus effected, and though the patient complained of severe pain in the anal orifice and the colon, she made a good recovery.

Mr. J. T. Wright, (Liverpool.)—It shall appear in due time.

JEREMY BENTHAM.

To the Editor of THE LANCET.

SIR,—The following letter concerning the body of Jeremy Bentham which I received from the late Dr. Southwood Smith in 1857, may possibly be worthy of a place in THE LANCET. It supplements the information supplied to you by my friend Dr. Lloyd, of St. Leonard's, in your issue of Oct. 16th, and in one respect corrects that of your correspondent, "J. T.," in the previous number.

"The Pines, Weybridge, June 14th, 1857.

"MY DEAR SIR,—Jeremy Bentham left by will his body to me for dissection. I was also to deliver a public lecture over his body to medical students and the public generally. The latter was done at the Webb-street School, Brougham, James Mill, Grote, and many other disciples of Bentham being present. After the usual anatomical demonstrations on the body, a skeleton was made of the bones. I endeavoured to preserve the head untouched, merely drawing away the fluids by placing it under an air-pump over sulphuric acid. By this means the head was rendered as hard as the skulls of the New Zealanders, but all expression was gone of course. Seeing this would not do for exhibition, I had a model made in wax by a distinguished French artist, taken from David's bust, Pickersgill's picture, and my own ring. The artist succeeded in producing one of the most admirable likenesses ever seen. I then had the skeleton stuffed out to fit Bentham's own clothes, and this wax likeness fitted to the trunk. This figure was placed seated on the chair in which he usually sat, and one hand holding the walking-stick which was his constant companion when he went out, called by him 'Dapple.' The whole was enclosed in a mahogany case, with folding glass doors. When I removed from Finsbury-square I had no room large enough to hold the case. I therefore gave it to University College, where it now is. Anyone may see it who inquires for it; but no publicity is given to the fact that Bentham reposes there in some back room. The authorities seem to be afraid or ashamed to own their possession.

"I am very faithfully yours,

"Dr. Munk." "SOUTHWOOD SMITH.

The history of the wax model and Dr. Southwood Smith's emphatic testimony to its likeness to the original are interesting points in the above letter.

I am, Sir, yours faithfully,

Finsbury-square, Oct. 23rd, 1875. WILLIAM MUNK, M.D., F.S.A.

A SMALL MOTIVE.

To what base uses may we come after death, and by what small motives are we influenced during life. The last mentioned circumstance is occasionally advantageous. Not even sprinkling the roads with salt in winter will induce ladies to wear shorter dresses. They only complain of the injury done to their skirts by the saline, wholly forgetful of the mischief wrought to apparel by habitually sweeping the streets of all description of dirt and abomination. Now, however, it is thought there will be a reform, and for this most wonderful of reasons. A boot has, it is said, been devised, curiously fashioned of velvet, and altogether so delectable that it must needs be displayed. Anything that will induce women to abstain from trailling their robes in the streets, and incommoding the other part of creation, if not themselves, must be welcomed. Meanwhile, it would be more satisfactory if reason swayed where all but fashion fails.

Mr. Charles Hunter is thanked. We regret, however, that want of space will not permit us to publish the communication.

Dr. James Adams.—Thanks.

Mr. W. Berry, (Wigan.)—The paper came safely to hand, and shall receive consideration.

DEAD BODIES.

AT a recent meeting of the Marylebone Board of Guardians the Workhouse Visiting Committee reported as follows:—

"We find, from a return presented by the master, that during the year ended August last 432 dead bodies were removed from various parts of the parish to the infirmary deadhouse, the removal in most cases being effected by inmates of the workhouse sent out for that purpose; that the Committee consider it very undesirable for inmates to be so employed, and think it is most dangerous for so large a number of bodies, in various stages of decomposition, to be brought through the yards and buildings of the workhouse, and deposited in a deadhouse situate in immediate contiguity to the infirmary wards. That of the 432 bodies above named, the Committee find that 169 were removed at the request of the coroner's officers for the purpose of inquests being held thereon (in most cases necessitating the performance, also in the deadhouse, of post-mortem examinations), and the Committee recommended that the coroner be informed that such practice must be discontinued. That 23 of the bodies were brought by the police and 240 by order of the relieving officers for the purpose of burial, and the Committee recommended that a communication be made to the vestry, asking that the mortuary, situate in Paddington-street, may be used for the reception of these bodies. The Committee further recommend that the attention of the Out-Relief Committee be called to the apparently large number of burial orders given by the relieving officers."

PHYSICAL EDUCATION.

THE *Local Government Chronicle* states that the Croydon guardians, who have just made their annual inspection of the North Surrey District School at Anerley, report very favourably of the arrangements of the school. A swimming bath is one of the new features of the establishment, and, on the occasion of the visit of the guardians, a group of boys were made to illustrate a boat accident, and were suddenly and simultaneously swept into the water, accoutred in their ordinary clothing and heavy boots. Despite these drawbacks, they showed that they could quickly recover themselves, and that if they had to contend with a real instead of a simulated accident there would have been no fatality. Next a "dummy" of about half a hundred weight was brought in, and was thrown to the bottom of the bath to represent a drowning person. A group of boys dived after it in succession, and each managed to bring it out of the water with considerable dexterity. Although the swimming bath has not long been an institution of the place, about 150 boys have been taught to swim, and it is also contemplated to teach the girls.

Mr. Thos. Moore.—It shall be published.

"CHEAP DOCTORS."

To the Editor of THE LANCET.

SIR,—I am sure that you would not willingly asperse the character of any medical man, nor wilfully misrepresent his actions, and it is this feeling that prompts me to seek at your hands redress for an injury you have unintentionally committed. I refer to a paragraph amongst the annotations of THE LANCET of Sept. 25th, which, owing to my not being a subscriber to your paper, I only became acquainted with a few days back by a medical friend writing and telling me of it.

Your informant must have either wilfully misrepresented the facts or withheld part of them from you, and it is the opinion of several medical men in the neighbourhood that whoever prompted the article in question must have done so maliciously. A brief summary of the facts as they are will, I feel sure, lead you to alter your opinion.

To begin with. I quite agree with you that the man who professes to attend the poor *for profit* for such a sum as I do is deserving of the stricture your paper has passed upon me; but, before I go further, let it be distinctly understood that I had the hope that the majority of my old club patients would avail themselves of the clubs of my medical brethren around me. I only started my present system for the benefit of those who would prefer remaining with me to being attended by other medical men, as I felt that I was bound, living in a country district, to do some sort of charity towards those of the poor who placed confidence in me. The cheap rate of attendance was fixed by me from the knowledge of the scanty means my club patients possessed, and the knowledge also of the fact that a ready money payment, however small, would act as a deterring influence on the greater number of them, and prevent them sending for me to call at their houses for trivial complaints which ought to have been brought to the surgery. The experience of the past quarter has amply proved me to be correct in my judgment, for I have only had to pay six visits to poor people at the rate of sixpence a visit; and if my clubs had been in existence I should have had to pay at least five visits a day to club patients, which would have been a total of *four hundred and fifty-five* in the quarter, the distance ranging from one to five miles. My surgery experience is as correct as that applying to the visiting; for instead of having from ten to fifteen bottles of club medicine at least to put up in a morning, I now have rarely more than three or four. Incredible as it may appear to you, the small rate charged by me is considered by the poor to be oftentimes beyond their means. The larger number of my old club patients have gone to other medical men, and I have not attended a single patient, to my knowledge, on my new terms during the past quarter who did not before belong to my clubs.

So far from wishing to court poor practice, in addition to throwing over a very large club practice, I have resigned a union appointment which brought me in over £100 a year. The main reason for this course was that, owing to my large and scattered private practice, I was unable to attend to the poor without an assistant, and after having the misfortune to lose a good one I had a run of bad luck in those that followed. I was obliged to make eight different changes in the short space of a year and a half. This you may imagine was most annoying to me and perplexing to the poor, and I determined to throw the clubs up at the end of the Midsummer quarter, their payments having been made in advance.

At the wish of some of the clergy in the neighbourhood, who had been always kind enough to collect the quarterly payments in their respective parishes, I had printed some handbills for them to give to the people when they came to pay their Midsummer quarter's money, to make sure that no mistake should be made in the number of verbal explanations they would otherwise have had to enter into. The rest of them I had given away at my surgery to those who paid there, as it was impossible for me to go round to all, or even to write to them, to notify the change.

So far from not wishing to support the medical club system, I only wish all my poor patients would avail themselves of those around them. I had thought of giving gratuitous advice to that class of people, but thought I should damage the clubs of other medical men by so doing.

So long as the poor think my terms too high, there is no fear of my bringing "medical services" into contempt in this neighbourhood; and I can assure you that if I found my charge insufficient to keep off the crowds of poor patients that used to hamper and keep me at work night and day, I should double it at once.

You will be conferring a great favour on me if you will allow the facts I have stated to you to appear in your next issue, that the profession at large may at least see both sides of the question.

I remain yours faithfully,

Nayland, Colchester, Oct. 22nd, 1875. H. D. PALMER.

⁂ We gladly insert Mr. Palmer's letter; but it does not alter our opinion. To circulate handbills intimating that advice and medicine may be had for threepence is a very indirect way of helping the club system. It is curious to note the different experience of Mr. Palmer and our correspondent "S." in regard to the effect of low charges. Mr. Palmer uses them to deter, and "S." to attract the poor.—ED. L.

"HUMAN REMAINS."

IT is to be regretted that medical men and students having need of "subjects" or parts of bodies are not more careful in disposing of them. The Anatomy Act, rigorously applied, provides amply for the burial of all bodies dissected at schools of medicine; but every now and again we hear of bones and parts of subjects buried in back gardens and otherwise irregularly distributed. Not only does the "discovery of human remains" create a most undesirable impression, it misleads the police, and is turned to a mischievous purpose. No obstacle would be thrown in the way of legitimate study, and it would be more in accord with the public sense of decency if the supply of such natural objects as are necessary were placed under judicious control, and the irregular possession or disposal of "remains" were treated as a misdemeanour. These irregularities are certainly an offence against prudence and common sense.

M.D., (Dublin.)—It was Hufeland, we believe, who noticed the comparative longevity of schoolmasters, and attributed it to their being so much in the society of young persons.

HOW INFANTS DIE.

To the Editor of THE LANCET.

SIR,—As a small contribution to the causes of infant mortality, perhaps the following may not be uninteresting. The practice of sending for a medical man at the eleventh hour is, I believe, almost everywhere prevalent.

Whilst *locum tenens* in a manufacturing town in Yorkshire this summer, I was sent for in the evening to see a child (an infant), which on my arrival I found almost moribund and insensible, evidently proceeding from weakness and exhaustion. I was told that it had been suffering from diarrhœa for several days, and had got much worse to-day. I ordered the people to send up immediately for medicine, and ordered brandy-and-milk to be given. The father came up in about an hour and a half, and said the child was dead. On my remonstrating with him for not sending up at once for medicine, he said the child had "worsened" after my departure, and he did not think anything would do it any good. I gave a certificate.

Another time I was sent for to see a similar case, where the child had been sick and purged for several days. This was a bastard child, and the father of the mother, who came, told me that there was "so much bother kicked up if a child *happened* to die without having a doctor to attend it." This child was not so bad as the last, and got better; but I have no doubt, from the conduct of the grandparents of the child, had they not fully believed that all hope of recovery was past, they would not have sent even when they did.

In death in such cases the medical man can do nothing but give a certificate. If he refer the case to the coroner, that omniscient functionary "sees no necessity for an inquiry." I am, Sir, yours &c.,

Chorley, Oct. 25th, 1875. M.R.C.S. ENG.

Mr. Alex. Duke.—There is such a dislocation; but it is of extremely rare occurrence, unless in connexion with fracture of the lower end of the radius. When our correspondent speaks of the sigmoid cavity of the radius, he, of course, refers to the semilunar cavity. Dupuytren met with but two cases. Sir Astley Cooper does not record a single instance. Malgaigne has collected about twenty cases of dislocation of the lower end of the ulna forwards or backwards; the latter the more frequent. Our correspondent will consider whether it is worth while going to law to vindicate his conduct. He will perhaps find more satisfaction in thinking that he has seen and reduced a dislocation so uncommon as to be unknown to a rival practitioner, who does not seem to have acted over courteously.

THE FLEXIBLE STETHOSCOPE.

To the Editor of THE LANCET.

SIR,—You have honoured the flexible stethoscope with a special notice, somewhat damning it with faint praise. Having used exclusively this instrument for upwards of forty years, I may be perhaps considered as having sufficient experience in its use to have arrived at some conclusions respecting it. I believe its advantages to consist in its capability of perfect adaptation to the parietes of the chest; its capability of application ordinarily with little or no disturbance to the patient; but, most of all, in the purity of the sounds it conveys, in consequence of having only one medium of conveyance—viz., the air contained in the tubing causing no confusion with that transmitted by the wood of the ordinary stethoscope. I believe any ear-piece attached to the gutta-percha tube to be injurious, as the end of the tubing itself adapts to the meatus more accurately than an ivory or wooden ear-piece. This is a most important consideration. My first use of the flexible stethoscope was suggested to me by Dr. Sibson during his residence as house-surgeon to the Nottingham General Hospital, and, as far as I know, Dr. Sibson is entitled to any commendation which may attach to its invention.

This stethoscope may be made by any person at about one shilling outlay. I leave to those who have brought it as a new instrument and a recent invention before the profession to explain their grounds for such an assumption, and remain, Your obedient servant,

Scarborough, Oct. 21st, 1875. R. S. HUTCHINSON, M.D.

VACCINATION IN YUCATAN.

IN 1848 the population of this peninsula was 60,000; but in two years it dwindled to about 30,000, in consequence of a war with the Indios bravos, and especially through an epidemic of small-pox. To prevent the ravages of this disease, the Government decreed compulsory vaccination; but the decree has had no effect, as the Yucatanese believe that the pits of small-pox are signs by which the Virgin Mary recognises her servants, for whom exclusively the gates of heaven are open. Thus the inhabitants object to vaccination, and those upon whom it is forcibly performed cut off the piece of skin on which the vaccine matter has been deposited.

THE STUDY OF ORGANS EXTRACTED FROM THE BODY.

AT the late Congress of Brussels, Dr. Heger read a paper on Artificial Circulation. This consists in killing an animal, and removing from it a viscus, as, for instance, the liver, the lung, or kidney. The circulation is kept up in the organ by means of defibrinated blood taken from the same animal or one of the same species. A viscus extirpated from an animal retains its vitality for some time; and when this viscus is kept, as it were, alive by artificial circulation, its functions and its peculiar properties may be studied. Experiments have gone further in these researches, and even the action of medicines, as atropine and chloral, has been watched upon isolated and extirpated organs kept alive by artificial circulation.

A NEW PHASE OF QUACKERY.

AT the Guildhall Police Court a few days ago a representative of the *Morning Advertiser* waited on the Alderman presiding, to ask whether some steps could not be taken to put a stop to the following disreputable proceeding:—A quack, giving an address in the City, was in the habit of sending circulars relating to certain medicines to every barmaid who advertised for a situation. Such circulars, the applicant contended, must have an injurious effect morally. The Alderman regretted he could do nothing in the matter. He would, however, place the documents in the hands of the police. It is quite conceivable that a very serious amount of evil may be caused by the dissemination among young women of such literature as that hinted at in the Court. We hope the police will see their way to preferring a charge against the offender.

Pelham.—The Local Government Board may sanction an appointment under the circumstances mentioned by our correspondent; but it is not likely to do so, unless special reason is shown for such a course.

Mr. P. Carden is thanked.

COMMUNICATIONS not noticed in the current number will receive attention in our issue of the ensuing week.

COMMUNICATIONS, LETTERS, &c., have been received from — Dr. Munk, London; Dr. Brown-Séquard, Paris; Mr. Soelberg Wells, London; Dr. Spencer Thompson, Torquay; Dr. Wiltshire, London; Mr. Gamgee; Mr. W. F. Teevan, London; Dr. Broadbent, London; Dr. William Carr; Rev. W. D. West; Mr. L. Egerton, Glasgow; Dr. Brushfield, Woking; Mr. Hughes, Calais; Surgeon-Major Rogers; Dr. Adams, Secunderabad; Dr. Bailey; Messrs. Kinmond, Leamington; Mr. Pocknell, London; Mr. Crookshank, London; Dr. Fox; Dr. Hutchinson, Scarborough; Dr. J. Morris, Barnsley; Mr. Rodwell, Norwich; Mr. P. Teale, Leeds; Mr. Holder, Hull; Dr. Foster, Birmingham; Mr. Lascelles, Chorley; Dr. Farquharson, London; Mr. Cooke, London; Mr. Hunter, London; Mr. Berry, Wigan; Mr. Radford, Aspall; Mr. Brett, Watford; Mr. Duke, Aberdeen; Mr. Redwood, Rhymney; Mr. Dowse, Highgate; Mr. Hall, Needham Market; Messrs. Medical Diary for the ensuing Week.

Monday, Nov. 1.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

ST. MARK'S HOSPITAL.—Operations, 9 A.M. and 2 P.M.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

MEDICAL SOCIETY OF LONDON.—8 P.M. General Meeting; Revision of Laws. —Mr. Jabez Hogg, "On Concussion of the Spine, followed by Impairment and Loss of Vision." — Mr. W. Adams will exhibit a Patient on whom he had Operated for Obliteration of Depressed Cicatrices.

Tuesday, Nov. 2.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

PATHOLOGICAL SOCIETY OF LONDON.—8½ P.M. The following Specimens will be exhibited:—Calculi of Cystic Oxide; Epithelioma of Tongue and Jaw; Cancer of Rectum—Colotomy; Carcinoma Lipomatosum; Distended Diverticula of Intestine; Pulmonary Embolism; Tubercle of Pancreas; Tumour in Upper Jaw; Double Cancer of Male Breast; Tubercular Lupus of Tongue and Palate; Fatty Tumour in Male Breast; Abscess in the Heart; Syphilitic Heart; Syphilitic Pneumonia; Parts after Tracheotomy; Aneurism of Aorta; Elio-sarcoma of Brain; Syphilitic Disease of Pharynx and Larynx; &c. &c.

Wednesday, Nov. 3.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. MARY'S HOSPITAL.—Operations, 1¼ P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1½ P.M.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

OBSTETRICAL SOCIETY OF LONDON. — 8 P.M. Dr. Geo. Roper, "On Prolapse of the Funis during Labour." — Dr. Swayne (Clifton), "On a new form of Blunt Hook and Sling for assisting Delivery in Breech Presentations."—Mr. Lawson Tait, "On a Case of General Dropsy in a Fœtus"; "Note on a Diseased Placenta."—Dr. Heywood Smith: "Notes of a Case of Ruptured Vagina during Labour, with Recovery."—Dr. Wiltshire: "Spontaneous Rupture of the Vagina; Recovery."—And other communications.

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. H. C. Sorby, "On a New Method of Measuring the Position of Bands in Spectra."

Thursday, Nov. 4.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

HARVEIAN SOCIETY.—7¼ P.M. Council meeting.—8 P.M. Dr. A. Meadows, "On the Diagnosis and Treatment of the Curable forms of Fibroid Tumours of the Uterus."

Friday, Nov. 5.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1¼ P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, Nov. 6.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NOTICE.

In consequence of THE LANCET being frequently detained by the Post Office when posted for places abroad *more than eight days after* publication, subscribers and others are reminded that such copies can be forwarded only as book packets, and *prepaid* as such.

TERMS OF SUBSCRIPTION TO THE LANCET.

Lectures
ON SOME
NERVOUS DISORDERS THAT RESULT FROM OVERWORK AND MENTAL ANXIETY.

BY GEORGE JOHNSON, M.D., F.R.S.,
PROFESSOR OF MEDICINE IN KING'S COLLEGE; PHYSICIAN TO KING'S COLLEGE HOSPITAL.

LECTURE III.

GENTLEMEN,—I described to you in my last lecture many of the symptoms and signs of functional disturbance in various organs which may have their origin in mental and emotional influences. I now wish to point out to you that some of the most formidable disorders of the nervous system may result from the same causes. A study of the more serious consequences of excessive brain work and of mental anxiety and shock will serve to impress upon you the practical importance of an exact diagnosis and appropriate treatment in the early stages of these disorders of the nervous system.

There are few diseases more terrible than epilepsy, and this dreadful malady is one of those which are often traceable to causes such as we are now considering. Many years ago, when I was physician to the Public Dispensary in Carey-street, and afterwards when seeing out-patients as assistant-physician of the hospital, I obtained the histories of a large number of cases of nervous disease, and I will now give you, as briefly as possible, the results of that inquiry, so far as relates to the exciting causes of epilepsy. On analysing the histories of 37 cases of epilepsy, I found that no less than 28 were probably the result of what are commonly called and understood as mental influences. In 5 the fits were the result of some obvious bodily disease or of intemperance, and in 4 no probable cause could be assigned. The cases of epilepsy to which I have referred as having their origin in influences acting primarily on the mind, naturally divide themselves into two classes, distinct, though closely allied. 1. The first class includes those cases in which epilepsy has resulted from great terror or excessive and sudden grief, and in which the first fit comes on almost immediately after exposure to the exciting cause without being preceded by warning symptoms. 2. In the second class are included those cases of epilepsy which arise from excessive mental work or continuous grief and anxiety, and which are preceded for a variable period by warning symptoms. Out of the 28 cases to which I have referred, 11 belonged to the former class and 17 to the latter.

Amongst the exciting causes which have acted suddenly in producing epilepsy, I may mention the sight of a supposed ghost which had been dressed up in order to terrify. In one case the ghost was a boy covered by a sheep-skin. One girl attributed her fits to the fright of hearing a knocking, which she believed to be supernatural. A woman became epileptic on hearing of the sudden death of a friend; she felt, as she said, "a sudden turn and agitation," and within an hour she had a convulsive fit. A man walking along the street saw a workman killed by falling headlong from a scaffold close to his feet. Instantly the horrified passenger fell in an epileptic fit, and he had been epileptic for years when I saw him and obtained his history. A boy was playing in the street, when a policeman terrified him by threatening to take him to the station for making a noise. He ran a few yards, and fell in a fit at the door of his house. The fits recurred, he became paralytic, and died two years afterwards.

When epilepsy results from a sudden mental shock, the first fit usually occurs immediately or within a few hours; but in some cases an interval of days, weeks, and even months, may intervene, the patient meanwhile manifesting signs of nervous disorder. The most remarkable example of a mental shock renewed and aggravated by nightly recurring dreams, and at length, after an interval of two years, culminating in epilepsy, is afforded by the second case, whose history I gave in my first lecture. From what I have seen of analogous cases, I believe that the habit of dreaming might have been checked and the chain of morbid phenomena broken by a judicious use of soporifics at any time during the two years before the occurrence of the epileptic convulsions.

Those cases of epilepsy which result from excessive brain work, from anxiety or continued grief, are usually preceded by a train of nervous symptoms; and it is during this period of what we may call the incubation of the disease that preventive measures may be resorted to with a reasonable hope of success. The symptoms which precede the full development of epilepsy are similar to those which I described in my last lecture as resulting from mental shock and anxiety: terrific dreams and visions, starting, struggling, talking, moaning, and sometimes screaming during sleep; a sense of fatigue in the morning, the patient often declaring that he is more tired when he gets up than when he goes to bed; often there is a sense of pain, weight, or constriction in the head, loss of appetite, disorder of digestion, and general weakness. These symptoms continue for a variable period, sometimes for many months, but in other cases only for a few weeks or even days, before the occurrence of the first epileptic fit, which generally takes place in the night, and during sleep. The nocturnal disturbances then continue, sometimes in an aggravated form; and after an interval, which varies from a few hours to several months, a second fit of epilepsy occurs, and so by degrees the disease is established.

Now, let me here guard against a possible misconception. I do not maintain or believe that every overworked or anxious man whose sleep is disturbed by terrifying dreams, or who talks, screams, or starts up in his sleep, will necessarily become epileptic or insane. Such an opinion would be very unreasonable, but, expressed in the hearing of one of these nervous patients, it might contribute much to bring about its own verification. The symptoms which I have described indicate, as the doctor says of Lady Macbeth, "a great perturbation in nature," which, if neglected, may lead on to epilepsy, or an outburst of delirium or mania. Obviously, then, they demand the most earnest attention, with a view to ascertain their cause, and then to find a remedy.

CASE 6.—One of the worst cases of epilepsy from overwork which I have ever met with was that of a youth, R. M——, who at the age of eighteen was a patient at the hospital. The disease had commenced about five years before. He was then a very intelligent boy, of a somewhat excitable temperament, and he was employed as a reader in a printing office. He worked at that occupation about ten hours a day in a close room. For about a month before the commencement of the fits he often complained of feeling tired and stupid, and he suffered from headache; at the same time, too, his parents noticed that he talked much in his sleep, and sometimes walked about the room in a state of somnambulism. At length he was seized with a violent fit in the night, and after a few days he had a second fit. The fits then recurred frequently, his memory and most of his mental faculties gradually became impaired, and he was soon rendered unfit to continue his occupation as a reader. The boy's parents were healthy, and there was no evidence of hereditary tendency to nervous disease. Now there is reason to believe that a holiday or a diminution of his daily work, with the aid of some sedative at night during the month in which the warning symptoms of coming mischief presented themselves, might have saved this poor boy from the misery of an incurable epilepsy.

The following case presents some interesting and instructive features:—

CASE 7.—In March, 1851, I was called to see a merchant's clerk (J. R. S——), aged twenty-eight. I was told that he had been delirious for three days. I found that his head had been shaved, his temples leeched, and his neck blistered, and he had been kept on a rigidly low diet. The result of this treatment had been an increase in the violence of the paroxysmal delirium, but at the time of my visit he was quiet and answered questions rationally. His skin was cool and moist, his pulse moderately quick, and his pupils natural. I ascertained, not only from his family, but also from his employers, that he was a very steady and temperate man. His wife told me that for several weeks before his illness his nights had been very disturbed; that in his sleep he had talked almost incessantly of his business; that in the morning he appeared unrefreshed; that his appetite had been bad; and that he had been gradually losing strength. When I inquired for the cause of all this disturbance, I was told that the fatiguing and harassing nature of his employment was the only cause for anxiety of which his family were aware. It seemed evident that the case should be treated as one of delirium from exhaustion; and accordingly I prescribed a mutton chop with a glass of porter, and at bedtime forty drops of laudanum. The next day I found that he had slept well and there had been no return of the delirium. He rapidly recovered, and at the end of a week he returned to his employment. About three weeks after he had returned to his work I was asked to see him at his employer's warehouse, where I found that he had suddenly fallen in an epileptic fit whilst engaged in washing his hands. I again inquired particularly for sources of anxiety, and I was again told by his family that overwork was his only trouble; but his employers, who were friends of my own, assured me that there was nothing in his work to trouble a healthy man. The fits recurred again and again. His wife told me, in the month of October, that his nights were constantly disturbed by dreams, and that he talked, moaned, and frequently called out in his sleep. He became a confirmed epileptic, was soon compelled to give up his situation, and about two years afterwards died. It was not until the month of February, 1852, nearly a year after I first saw the patient, that I learnt the real cause of his nervous disorder. His father then told me that my patient's wife was a confirmed drunkard, and that when drunk she was extremely violent; that she had more than once threatened to stab her husband, and that on one occasion she had actually wounded his hand with a knife. My informant had from the first been aware that this was the cause of his son's misery and restlessness; but he was unwilling to speak of it, even to me, until matters had become desperate. It is evident that the information thus tardily given is the central fact in the history of the case, and until its sad domestic history was revealed there appeared no satisfactory explanation of the poor man's continued and increasing nervous disorder.

I have seen other cases similar to this within a comparatively recent period in private practice, but for obvious reasons it would be inexpedient to publish them.

The delirium which occurred in the early period of this case is a good example of the kind of delirium which is sometimes brought on by intense mental anxiety in persons of strictly temperate habits. Great and sudden terror may be followed almost immediately by maniacal delirium. Quite recently we have had in the hospital a boy fifteen years of age, who became violently delirious immediately after being terrified and assaulted by two men as he was returning from his work in the neighbourhood of London. But the delirium which results from overwork and anxiety rarely if ever occurs without being preceded for a variable period by disturbed sleep, and the other signs of nervous disorder which I have before described. Sleep-talking and somnambulism are amongst the most frequent precursors of delirium. When an anxious patient is talking in his sleep he will sometimes answer questions as if all his faculties were alive, and yet, when he awakes, he may have no recollection of what he has said or heard. In other cases he appears, while sleeping, to be carrying on a conversation with someone whom he imagines to be present. I was once told by a very intelligent woman that her husband, who ultimately became insane, was of what she called "a very close disposition," so that he would never willingly speak of his troubles to her or to anyone; but whenever he had been unusually worried, he talked so much in his sleep that she heard from him then, not only that he was anxious, but also the cause of his anxiety. "Infected minds to their deaf pillows will discharge their secrets." The transition from a state of delirious sleep to delirium in the waking condition may be direct and rapid, but there sometimes occurs a transient intermediate stage, during which a man starts up in a state of confusion and terror, looking about him distractedly, and perhaps talking wildly, and recovering complete consciousness and self-possession only after being frequently spoken to and roused by being touched or roughly shaken.

CASE 8.—Many years ago, when I was house-physician of the hospital, I had under my care a shoemaker whom I had known for some time as an excitable man of intermittingly intemperate habits. He had now a sharp attack of gout, and one evening he astonished the ward by setting up a loud and continuous shouting. I was called to him and found him still roaring at the top of his voice, and as he continued this in spite of my loud remonstrance, I took him by the shoulders and gave him a vigorous shaking. This immediately stopped the noise. The man had been terrified by a dream, and he was only half awake until I roused him by the shaking.

In some instances the excitement on first awaking is accompanied by a temptation to commit suicide, or to do violence to others; and the patient will afterwards speak of these feelings as most distressing and terrible. In other cases he begs that he may not be left alone lest he should destroy himself, or that those whom he most loves should remain away lest he should injure them. These symptoms, if permitted to continue unchecked by judicious treatment, may be quickly followed by an outburst of maniacal delirium, or by an epileptic seizure, or sometimes, as I have seen in several instances, by both these terrible consequences in succession. In no case whose history I have investigated has an outbreak of delirium of this kind occurred without being preceded for a longer or shorter period by some of the premonitory symptoms which I have described. I have heard and read of men becoming suddenly delirious and mad without warning or any discoverable cause. I have never seen such a case, but I have met with more than one which, without a careful examination, might have passed for such—cases in which there was a deep and abiding cause for anxiety which was not revealed, even to the nearest relative or friend, until it was discovered after it had wrought irremediable mischief on the nervous system of the patient.

CASE 9.—One such case was that of a clergyman whom I had known for some years as a man of powerful mind and body, until, to the surprise and grief of his family and friends, he suddenly, as it appeared, became insane, and subsequently epileptic, when he was just over thirty years of age. His habits were strictly temperate, but he was disposed to be over-anxious about his parochial work. His wife observed that his appearance and manner were changing; he became unusually reserved and sometimes irritable. He was at a distance from all other members of his family, and his anxious wife had no suspicion either of the real cause of the change which had come over him or of the serious consequences which were threatened. At length he became suddenly and furiously delirious in the middle of the night. The mental disease continued and became complicated with epilepsy; and after nearly four years of suffering he died. Now the cause of this terrible calamity was not discovered until the time for prevention had passed. His income was limited, and insufficient for the wants of an increasing family; he was in pecuniary difficulties of which no one but himself knew until the state of his affairs was disclosed after his illness. He was naturally reserved, sensitive, and proud; and he had concealed his difficulties from his wife, probably from an unwillingness to distress her with a knowledge of them. Of course his own anxiety was intensified by this reserve, and by his not seeking that relief which might have been obtained if he had imparted his troubles to his family and friends.

CASE 10.—In September, 18—, I was consulted by an officer, aged forty-six, in a high position in the army and in society, on account of an attack of loss of consciousness, which had occurred while he was in bed three days before I saw him. I inferred from his description that he had had an epileptic attack. I observed that he had what I have described as the "anxious eye"; but, in reply to my particular inquiries, he assured me that he was not overworked, and that he had nothing to trouble him. I saw him again in a few days, when I repeated my inquiries and received the same answer. In November his sister called to tell me that he was in the country acting very strangely, and evidently insane. I inquired for sources of mental anxiety, and was told that it had recently come to the knowledge of his family that some years since he had formed a *liaison* with a lady, by whom he had had several children, and whom he had recently married. For reasons which need not be mentioned here, this affair had for some time caused him the most intense anxiety, and was without doubt the cause of his mental derangement. He came up to town in a state of maniacal excitement. I had a consultation with Dr. Monro and with the surgeon of the regiment. He was sent to an asylum, where he was generally happy in the belief that he possessed boundless wealth. He had occasional epileptic fits, and after some months he had a rapid succession of epileptic attacks and died.

I could give the details of a considerable number of cases of whose history I have an intimate knowledge, in which consequences equally disastrous, though differing in different cases, have resulted from similar causes, and especially from the influence of suppressed grief, care, or anxiety, the cause of which has been neither known nor suspected by the patient's nearest friends, until it has been brought to light after the onset of some alarming illness—an attack of mania, or epilepsy, or paralysis. Now, in order to prevent these calamitous results, it is of the highest importance that the true nature of these interesting cases should be recognised in their earliest stages, when preventive treatment is often attended with complete success. It often happens that we are consulted by an anxious patient who believes that he has some serious organic disease, and who complains of some of those symptoms of nervous disorder to which I have so often referred. He feels certain that his heart, or his lungs, or his kidneys, or perhaps his brain, must be in a state of incurable disease. We notice the patient's anxious appearance and manner, and, after inquiring for other sources of disorder, we arrive at a positive conviction that all the symptoms have their origin in some disturbing mental influence. If, then, we express this opinion to the patient we shall probably so far gain his confidence as to obtain from him an acknowledgment of trouble and anxiety, of which perhaps he had never before spoken to anyone. Or, if he hesitate, as perhaps he may, to make a confessor of his physician, we may at least succeed in directing his attention to the true source and nature of his sufferings, and so induce him to confide in some friend, and thus put himself in the way of obtaining needful advice and assistance, while we carry on the medical treatment of his case. In this way we may often be instrumental in preventing the development of serious disease which, when it has passed beyond the initiatory stage, is cured with difficulty, if at all; while, on the contrary, an error of diagnosis—a failure to appreciate the nature and origin of the symptoms—may be attended with very disastrous results, partly by confirming the patient's hypochondriacal fears as to his health, and partly by suggesting a plan of treatment the reverse of beneficial.

Before leaving this part of my subject I may mention that when a patient has once been delirious or insane from the effects of mental anxiety, he is very liable to suffer from restlessness or to have his sleep disturbed by frightful dreams and visions, if at any time subsequently he is weakened by illness or over-fatigue, or exposed to mental worry. A woman who has once been in an asylum has several times complained to me of these nervous symptoms, and on each occasion she has been quickly relieved by an opiate at bedtime for a few nights in succession. In such cases it is probable that the mere dread of a return of the disease is often a source of great anxiety; and the same observation applies to epileptic patients. One man told me that he always sleeps soundly for a few nights after he has had a fit, and he explained this by saying that for some time after the occurrence of a fit he has no fear of an immediate return, which at other times he so much dreads that he cannot sleep with comfort.

Amongst the nervous diseases which are frequently the result of mental shock, *chorea* or *St. Vitus's dance* is well known to be thus excited in a very large proportion of cases. One of the most interesting problems in pathology is to explain the fact that chorea may result from such apparently different causes as the mental influence of terror and the mechanical plugging of minute cerebral vessels by fibrinous particles detached from an inflamed endocardium. I do not propose to discuss that question now, neither shall I attempt to account for the fact that a similar mental shock will excite in one patient delirium, in another epilepsy, and in a third chorea; but I wish to impress upon you a fact of practical importance with reference to the preventive treatment, which is this: that as in cases of delirium and of epilepsy excited by mental shock, so in cases of chorea, the symptoms of the special nervous disorder may not commence until some days after exposure to the exciting cause; but on careful inquiry it will generally be found that in the interval the patient's sleep is broken and disturbed by dreams, as a result of which the effect of the original mental shock is perpetuated and intensified until the nervous disorder reaches its full development.

CASE 11.—At the present time (December, 1874) I have in the hospital a boy fifteen years of age, in whom a severe attack of chorea was excited by fright. As he was walking in the dark a large black dog jumped over a fence by the side of the road, and came so close to him as to knock a basket out of his hand. He was very much frightened, but a week elapsed before the symptoms of chorea appeared. In the meantime, however, his sleep had been disturbed every night by terrifying dreams, which made him more and more nervous. The symptoms since his admission have rapidly yielded to the soothing influence of ten grains of chloral hydrate taken three times a day.

Now, the practical lesson which I wish to convey to you is this, that in all probability if he had taken a ten-grain dose of chloral at bedtime for three or four nights after his fright he would have slept without dreaming, his brain would have been soothed, and the mental shock therefore would not have developed into an attack of chorea.

The nervous symptoms which result from mental shock and emotional excitement sometimes assume the form of *hysteria*. Let me remind you that this disease is not necessarily, as its etymology would seem to imply, a result of uterine disease or irritation. Every one of its characteristic symptoms may be fully developed, not only in those who have a healthy uterus, but in those who do not possess a uterus. It is more common in women than in men, for the reason that the more excitable nervous system of females renders them more liable to this form of disorder. The globus hystericus—the sensation of a ball rising into the throat and threatening suffocation—is the form of hysterical symptom which I have observed more frequently than any other in anxious patients of both sexes. It is always a distressing symptom, and it often alarms the patient greatly. This painful sensation is often excited by some sudden mental emotion, and it may occur at any period either of the day or night. In many cases, especially in men, it has been complained of only at night, and it has appeared to be connected with the distressing dreams by which the patient has been nightly disturbed. The dreams and the hysterical globus have both been cured by the same means.

CASE 12.—One of the most remarkable cases of this kind was that of a man sixty years of age, who assured me that for about a year he had scarcely passed a night without being disturbed by a frightful sense of suffocation, for the relief of which his son and daughter often had to assist him to the open window. He had no cough, nor was there any evidence of disease within the chest. His countenance was expressive of great mental anxiety, and he admitted that he had been much troubled by circumstances, the particulars of which he did not communicate. I prescribed a grain of opium in a pill every night at bedtime. He came again at the end of a week and told me that since taking the pills he had slept well, and had not once been disturbed by the horrible sense of choking which had so long distressed him. From that time I saw him no more; I therefore conclude that he had no return of his distressing complaint. I have seen many cases similar to this, as regards the symptoms, the etiology, and the results of treatment.

I have no doubt that in some cases the nervous sensation of globus is excited by some local irritation of the throat. When a nervous woman, or even a very nervous man, gets a common sore-throat, the distress and alarming sense of impending suffocation are often quite disproportioned to the physical changes in the throat which we can see with the laryngoscope.

CASE 13.—A poor woman who was very anxious and much overworked had a slight choking fit while she was eating, and afterwards she felt sure that some substance was still lodging in her throat. She went to one of the hospitals, where the house-surgeon passed a probang, but that rather increased her distress. When she came to me I found the mucous membrane of her fauces and pharynx congested, but her intensely anxious face and nervous manner, and her description of the "rising" in her throat, were the most significant facts. It was not until after many days, and then very gradually and with occasional relapses, that she escaped from the conviction that some solid mass was sticking in her throat and threatening suffocation.

Case 14.—Not long since I was consulted by an unmarried lady, about forty-five years of age, who for several months had been disturbed nearly every night by attacks of choking, which compelled her to sit up in bed. She had a pallid and delicate, but not an anxious look. On examining her throat I found that she had a very long and slender uvula, which was always in contact with the back of her tongue. I cut off about two-thirds of the uvula, and from that time she had no more attacks of suffocation. In this case I have no doubt that the distressing attacks of suffocation were excited during sleep by the elongated uvula.

ABSTRACT OF Introductory Lecture

Delivered at Glasgow University at the opening of the Medical Session 1875–6.

By GEORGE BUCHANAN, M.D.,

PROFESSOR OF CLINICAL SURGERY.

The lecturer, at the outset of his address, welcomed the students to the University, and expressed the hope that ere they parted at the close of the session that respect which ought always to be entertained by students to their professors might be augmented by that confidence and warm feeling which were the privilege of true friendship. He pointed out that upon the senior students devolved great responsibility. He did not hesitate to say that the value of the session would very much depend upon how they conducted themselves. The 300 old students would have an immense and a very important influence upon the studies of the juniors by their conduct and example. Consequently, he appealed to the senior students—the appeal was scarcely necessary—by the love they had for the University, and by their hope of success in future life, to show such an example to their juniors that the present session would not fall behind former ones in respect of diligence and earnestness. He keenly sympathised with the junior students who were at the University for the first time. He could easily understand the feeling of dismay with which they would look at page 99 of the Calendar, where there was detailed the amount of study which would be required of them before leaving the University. Most of the students who were present for the first time were comparatively ignorant—if not altogether ignorant—of medical science, and between the present day and that day four or five years hence, when the Principal would place upon their heads the much-coveted velvet cap, they would require to undergo a very remarkable metamorphosis. There was only one way in which the work could be done, and that was by using as their talisman the three words—"Regularity, method, and economy of time." As to regularity, let no student ever miss a lecture or demonstration unless absolutely compelled by ill-health or some necessary cause.

Medical science might be divided into two great parts—that of the principles, and that of the practice of the healing art. The latter was certainly the aim of medical education, but in order to a sound practice a man ought to be well acquainted with the principles of his profession. Hence he maintained that the grand object of the student in attending the University was to store his mind with the principles of his profession. "A knowledge of principles is to a certain extent a foreknowledge of events. Given certain agencies at work—an acquaintance with their properties enables us to foretell with considerable accuracy the result of their action. A common observer believes that the tide will flow and ebb to-morrow, because it has flowed and ebbed ever since he remembers, and he learns it has done so for ages back. But the astronomer knows that it must flow and ebb to-morrow, for the same cause which produces its movement to-day will act in the same way till disturbed by some other force. His knowledge is certain, being drawn from an acquaintance with the causes of the phenomena. If our knowledge of principles were perfect, our knowledge of events would be certain. Hence this acquaintance with causes, and the changes which they produce, is a far higher kind of learning than that derived from mere observation. What is true absolutely of mathematics, mechanics, and the exact sciences, is to a certain extent applicable to medicine. If our knowledge of anatomy, physiology, and pathology were perfect, we could foretell with precision the course and termination of every disease. And the more accurate our information on these points, the more correct will be our prognosis or prediction of the probable issue of any case of disease. So that it should be your aim during your student life to gain a good knowledge of those branches of medical study on which are founded the principles of scientific medicine." Professor Buchanan proceeded to say that the foundation principles of their science were chemistry, anatomy, and physiology. Chemistry was a fascinating science; but he was afraid there was a tendency on the part of students, in the study of it, to substitute ideas for things. The student seemed to devote a good deal of his time to the study of chemical nomenclature, and some of them were able to emit correct answers to chemical questions in hieroglyphics of which they could hardly expound the signification. He maintained that it was better for a student to know well, and to be able to handle a few substances, than to make any number of figures of which he did not thoroughly comprehend the meaning.

The lecturer passed on to say a few words to the junior students on the subject of physiology, a science which, he said, was advancing with such rapidity that the text-books of ten years ago were absolutely of no use. It consisted of two things—first, observation; and, secondly, reasoning on that observation. It was impossible for the students to observe all the tissues and facts that constitute physiology, and he advised that they should each of them obtain a thorough knowledge of one particular form—for example, a blood globule—which would illustrate the rest. With the view of carrying out this idea he suggested the formation of a Microscope Club, to meet on the Saturdays in a room in the University. When observations were made science was advanced by reasoning upon them, so that the two methods of scientific research were observation and theory. Theory might be familiarly described as the mind groping out in search of truth, a voyage of discovery after new territory of science, like Columbus on the Atlantic. As an example of a beautiful theory almost proved, but just waiting further corroboration, he instanced the germ theory of putrefaction. It is hardly possible to believe anything else than that putrefaction occurs by chemical changes produced by the presence of a germ, and the experiments could hardly be explained upon any other basis than that these germs, being in the atmosphere, were wafted towards them. They had never been seen or examined, however, and scientific men were waiting quietly for the elaboration of the means of examination and the greater perfection of instruments to enable them to see those at present invisible motes.

Of all the studies that engaged the attention of students, if there was one more important than another, that was anatomy. It had the peculiar characteristic that upon the day the student obtained his degree he was supposed to have knowledge of anatomy such as befitted a student of the University of Glasgow, but from the day the cap was placed on his head that knowledge gradually disappeared unless special attention was directed to it. When the young graduate commenced practice there was little time to devote to that purpose, so that in the course of a few years his knowledge of anatomy was a great deal less than when he sat on the benches of the College. The knowledge of therapeutics and pathology, and certainly of medicine and surgery, gradually increased the longer a man practised, and just in proportion the knowledge of anatomy went away. The practical branches would be the business of their lives, and having stored up thoroughly all knowledge of the fundamental branches and principles of the profession they would be prepared to pass on to the more important details.

As to the hospital practice, a great deal of difference of opinion existed as to whether a student should begin practice there in his early years or later in life. He was of opinion that for those who came to the University for the first time, and who knew nothing at all of medical science, it would be a waste of time to attend regularly the infirmary during the first winter session, and therefore they ought to devote their time entirely to anatomy and chemistry. There was a great tendency on the part of students to store and cram their minds with facts, so as to pass creditably at the examinations. He invoked them to get quit of that idea. The examinations were not so bad; they were really not so serious; they were meant to test if possible, not what questions the students could answer, but if they were fit for professional life; and if students would keep that in mind before the examinations, they would not trouble so much with mere question and answer. If it was in the power of the students after getting their degrees —either by saving up beforehand or obtaining a bursary— to keep about the College for a year longer, they would learn more in a month or two after their examinations were over than during all the time before.

The learned Professor concluded:—"I have embodied in the compass of a few sentences the varied and important studies which you must master if you wish to become successful practitioners of medicine. I think it is important at the outset that you should know what you have before you, and what will be expected of you, so that, setting yourselves fairly to the acquisition of the requisite knowledge, and disregarding all allurements which would tend to break your habits of study, you may in the end successfully obtain your qualifications to practise, and issue forth on your philanthropic mission, a credit to your University and an ornament to your profession. Let it not be supposed that I underrate the difficulties which lie before you; 'tis not so long since I grappled with them myself. I would have you often think of them—but with the determination to master them, not to succumb. Our profession is not a path strewed with flowers, either in its acquisition or its practice. Its acquisition is the result of years of earnest and laborious study, its rewards are often tardy of coming. It cannot be considered a lucrative one, and the first years of its practice are usually far from encouraging to the young aspirant. Yet when fairly engaged in active duty you will rarely find a medical man who would exchange his profession for any other. If it be the highest triumph of man's genius to save a fellow-creature from destruction—to rob the grim tyrant of his expected prey—how pleasing the reward which you will reap in the grateful thanks and untold blessings of the affectionate wife to whom you have restored a much-loved husband, of the fond parent to whom you have rendered back a darling child, of the faithful companion for whom you have regained a much-valued friend. It is in this view that you are to regard the true aim of medical science; it is in this aspect that you are to estimate its rewards."

ON A CASE OF

CONVULSION FROM BRAIN INJURY.

By W. R. GOWERS, M.D.,

ASSISTANT-PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

The investigation of convulsive seizures may throw light either on the relation of a given alteration in the brain to certain movements, and therefore on the localisation of function in the brain, or upon the laws which govern convulsive seizures considered apart from the special change which causes them. It is impossible to watch the course of many convulsions without being struck with their conformity to (and correlated divergence from) certain regular types. It cannot be doubted that the changes in the nerve centre of which the convulsion is the outward sign, possess certain common features in different cases apart from the locality of their cause. To these Dr. Hughlings Jackson has called frequent attention. The case described below throws little light on the localisation of function in the brain; for, although there was defined laceration, the whole of one hemisphere was exposed to pressure from effused blood. But the opportunity which it afforded of observing the exact characters and course of the convulsive movements, during a long series of fits, was such as to render it possible to ascertain with considerable minuteness the details of many attacks, and on this account it is described.

It will be convenient to give first an outline of the case, and afterwards to describe the details of the convulsive seizures.

A man, apparently about fifty years of age, was admitted into University College Hospital Nov. 30th, 1874, under the care of Mr. Erichsen, whom I have to thank for permission to watch the case. The man had fallen down in the street and had been picked up unconscious. When brought to the hospital he had partly recovered consciousness. He seemed to understand questions, but his answers were unintelligible. He intimated, in reply to questions, that he had pain in the head, but could not point out its locality. Some bleeding from the left ear was noticed, and subsequently some extravasations appeared beneath the left conjunctiva. In this state he lay for six days. On the sixth day convulsive attacks set in, and recurred day after day until his death, six days subsequently. In these attacks, as will be mentioned presently, the right side was affected much more than the left, and after they had lasted for two days there existed distinct right-sided weakness. After the commencement of the fits his mental state became much more dull. The character of his speech was doubtful. Sometimes a few words were uttered indistinctly, but apparently correctly; at other times he used words which were evidently not those which he meant to employ, and he occasionally uttered sounds which were apparently a meaningless repetition of certain syllables. His articulation was confluent—i.e., syllables were run one into another. Swallowing was difficult. His stools and urine were passed into the bed. His urine, towards the last, contained a little albumen, but no sugar. The convulsive attacks were at first very frequent, one occurring every few minutes both day and night; during the last few days they were less frequent. His temperature, never below 99°, rose, the day after the fits commenced, to 102°, and continued between 100° and 102° until his death. From the first there was rapid loss of flesh. The immediate cause of death was apparently asthenia.

Post-mortem examination.—A fracture was found in the left side of the skull, extending from above the occipital protuberance to the external meatus, into which it passed, and thence extended inwards as far as the roof of the tympanum. There was no hæmorrhage between the skull and the dura mater, but beneath the dura mater a thick layer of coagulum lay over the whole left hemisphere. The hemisphere itself appeared rather smaller than the right, and here and there the convolutions had evidently been flattened by the pressure of the clot. All the convolutions were blood-stained. The chief damage to the convolutions was in the temporo-sphenoidal lobe. The outer surface of this lobe in the posterior half was broken up by laceration and effusion of blood over an area of one square inch and a half. The middle convolution was that chiefly damaged. In front of this was a smaller area of laceration, involving the apex of this lobe and part above the apex, and this laceration was separated from the larger injury by an undamaged portion. Some softening existed in the margins of the lacerations. One or two minute lacerations existed in the anterior part of the inferior temporo-sphenoidal convolution. In the orbital lobule were one or two small spots of extravasation beneath the pia mater, and other small spots of laceration at the outer margin of the frontal lobe, about half an inch from the anterior extremity of the inferior frontal convolution. The rest of the convolution was undamaged, and so also was the island of Reil. There was no laceration of the superior middle or ascending frontal convolutions. The damaged convolutions showed, on microscopical examination, the evidences of acute inflammatory changes extending through the entire thickness of the grey matter. Further, adjacent convolutions, which were apparently intact, exhibited much disintegration of the grey layers. The convolutions at a distance from the damaged areas were healthy. Beyond some pneumonia of the lower lobe of the right lung no other disease was found in the body.

Description of the fits.—The fits presented, for the most part, considerable uniformity in the course and distribution of the convulsive movement. The part affected varied chiefly according to the severity of the fit; some attacks were slight, others were severe. It will be convenient to describe first the several degrees of what may be termed the typical attacks, and then the way in which some attacks deviated from that type.

In the slighter fits the head alone was affected. In the more severe attacks the head and right arm were involved; in the most severe attacks the head, right arm, and both legs were convulsed. In the slightest fits clonic spasm of the facial muscles alone was observed; in all the others tonic preceded the clonic spasm. There was no pallor at the outset. During the latter part of the severer attacks, in which respiration was interfered with, the face became dusky and congested.

Aura.—Most of the attacks were apparently preceded by some sensation about the mouth. There was an uneasy voluntary movement of the lips, and the hand was frequently raised to the mouth. Every time this occurred, after a few seconds a fit came on. Occasionally a slight cry preceded the fit, and during the severe fits a peculiar noise was made in the larynx.

Spasm of muscles of mastication, tongue, and palate.—In a large number of cases the first spasm occurred in the muscles attached to the lower jaw, and it commenced in these muscles simultaneously on both sides. The masseter and temporal muscles were both involved. The muscles above the hyoid bone, genio-hyo-glossi especially, were affected strongly, while those below the hyoid bone were almost or quite free from spasm. On opening the mouth with a screw gag while the clonic spasm was going on in the muscles of mastication, the tongue was seen to be moved rapidly in the same way. The tip was moved forward a little at each spasm, until at last the tip was thrust between the teeth. The palate was seen working up and down in rapid movement synchronous with the clonic spasm in the tongue and muscles of mastication.

Spasm in facial muscles.—After the clonic spasm had lasted for some seconds in the muscles of mastication, twitching began in the face, and usually commenced simultaneously in the right zygomaticus and the right platysma myoides. The right angle of the mouth was drawn outwards, and the platysma stood out conspicuously on the surface of the neck, the left platysma remaining still. Soon after the zygomaticus, the right orbicularis palpebrarum was contracted, and the spasm extended to the triangularis nasi and the levator labii superioris. The left orbicularis palpebrarum was also slightly affected. Both corrugator supercilii muscles were involved, simultaneously and equally.

The head was either straight or directed to the right. The eyes were usually directed to the right, but presented in some fits a curious alternate movement from one side to the other, to be described presently. The pupils during these slighter fits were small throughout. The respiration was not impeded.

Spasm of right arm.—In the more severe fits the spasm invaded the right arm soon after affecting the face. It began in the deltoid, and involved the muscles of the upper arm before those of the forearm. Both flexors and extensors were involved. The position of the hand during the spasm was peculiar: the fingers were flexed; the thumb was flexed and bent under the first and middle fingers, so that its tip projected between the middle and ring finger. It continued in this position after the spasm ceased.

The *left arm* was always free from movement, except that in one or two of the most severe fits it was jerked as a whole by the contraction of the left pectoral muscles.

Spasm in legs.—In other, still more severe fits, the convulsion invaded *both* legs, soon after it commenced in the arm. The two legs were affected simultaneously, the *left* leg rather more severely than the right. Both were at first rigid in tonic and then jerked in clonic spasm. The right leg, however, was extended at all joints, so that it lay upon the bed; the left leg was slightly flexed at the hip and knee joints, in consequence of which it was raised about a foot from the bed, the thigh being at an angle with the trunk, and the leg parallel to the surface of the bed; it was held in that position.

Muscles of trunk.—The sterno-mastoid was involved on the right or left side at different times; the turning of the head was the result of its contraction. The trapezius was involved on the right side; it was not certain whether it contracted on the left side, but it was thought to do so in the severer fits. The pectoralis major was convulsed on the right side in all the fits in which the right arm was involved; that of the left side was still, except for a slight jerking in one or two of the severest fits. The intercostal and abdominal muscles were unaffected in the slight, but were involved in the severer fits, and then were affected together, and those of the two sides equally. The affection of these muscles and the consequent arrest of respiration occurred in all the fits in which both arm and legs were involved; in none of those in which the face alone was affected without the arm; while in the fits in which the face, head, and right arm only were affected, the legs remaining still, the respiration was arrested in the severer, and continued unaffected, or slightly accelerated in the slighter attacks.

The *pulse* became more frequent during a fit, and irregular towards its close. The pupils were dilated during the latter part of the severe fits.

Cessation.—The modes in which the convulsion ceased varied in different attacks. As a rule, the spasm ceased in the limbs some time before it ceased in the muscles of the face, but it occasionally ceased simultaneously in the arm and in the face, and even in the arm, leg, and face. In one severe fit the movement in the arm continued some time after that in the leg and face had ceased.

The *average duration* of each fit was one minute and three-quarters. The duration of the tonic stage was about one-fourth, that of the clonic stage three-fourths, of the whole duration of the fit.

Varieties in distribution of the convulsion.—In some fits the spasm did not extend to the upper part of the face, but was confined to the muscles of mastication, the right zygomatic muscles, and the right platysma. Some of the fits began distinctly in the right zygomaticus, without any preceding affection of the muscles of mastication. From the zygomatic muscles the spasm spread to the rest of the right half of the face. In these fits the right orbicularis only was involved, the left eye remaining widely open, while the right eye was forcibly closed. The occipito-frontalis muscle on both sides was involved. The eyes were sometimes directed towards the right, the axes being parallel; often, however, the eyes converged, the left eye being directed a little inwards, while the right was in the middle position. The eyes were occasionally jerked, conjugately, in clonic spasm, while clonic spasm was going on elsewhere.

Alternate movement in the head and eyes.—A curious alternation was observable in several fits in the earliest movements. In some, the spasm in the masseters was preceded by a slight twitch in the left angle of the mouth and left side of the chin. In other fits the first spasm was a slight movement of the head, first to the left, then to the right; and as the head turned to the right, the right side of the mouth became drawn outwards, and the fit followed, with spasm in the right side of the face, as already described. Very frequently the eyes were first directed towards the left, then to the right, in the way just described, as the convulsion involved the right side of the face; and were subsequently turned to the left, and finally back again to the right, in which position they remained for a minute or two after the fit was over. The position of the head, as a rule, corresponded to the movement of the eyes. The deviation of the head was distinctly the result of spasm in the sterno-mastoid on the side opposite to that to which the head was turned.

Ophthalmoscopic observation during the fit.—During one severe fit, in which the left eye remained open while the right was closed, I was able to watch a retinal artery and vein by the direct method of observation, from the very commencement to the end of the fit. Not the slightest diminution of their calibre could be observed; the artery remained of precisely the same size. When respiration was arrested and the face became dusky, the vein appeared distended and darker; no other change was observed. It is to be remarked, in connexion with this absence of spasm of the retinal vessels, that pallor of the face was likewise absent.

REMARKS.

Among the interesting points presented by the case is the commencement of the convulsion in the muscles of mastication. The involvement of those muscles in the course of a fit is common enough, but it is rare for them to be the seat of the first spasm in a convulsion of deliberate march. I am not aware that spasm in the palate has been before observed. Its distinctness in this case, and correspondence in time with the clonic spasm in the tongue and muscles of mastication, make it probable that the three are commonly associated.

Whilst the mouth was held open the mechanism of tongue-biting could be very distinctly observed — the gradual jerking forwards of the tongue till its tip was thrust between the champing jaws.

Relation of tonic to clonic spasm.—The essential unity in nature of the tonic and clonic spasm was in this case very distinct. At first the contraction appeared, to both eye and hand, to be continuous—i. e., tonic. Long before the least intermission in the continuity of the spasm was visible to the eye, the hand laid upon the convulsed part could detect that the apparently continuous spasm was really a succession of contractions which by their quick repetition produced a tetanic state, and, though they could not be seen, could be felt as rapidly recurring vibrations. Gradually, the interval between these contractions becoming longer, the intermission was distinctly visible, and, becoming still more complete, the characteristic clonic stage was developed.

I do not think that this relation between the tonic and clonic spasm has received the attention which it deserves. If the difference between them depend in all cases, as I believe it does, merely on the interval between the successive muscular contractions, and the transition between the two be perfectly gradual, it is not easy to accept the difference of cause commonly assumed for the two forms, and which refers the tonic spasm to the "spontaneous" undue action of the nerve-centre—the clonic to its irritation by venous blood. The inference from their essential unity is the unity of their cause.

The relative affection of the muscles of the two sides presented some peculiar features. The equal affection of the muscles of mastication of the two sides is in full accordance with their bilateral use. So, also, according to the usual law of convulsive seizures, the muscles of the forehead were affected simultaneously on both sides; while those attached to the angle of the mouth were affected only on one side at a time. Curiously, however, the orbicularis palpebrarum was affected on both sides in some fits; on one side only in others. The mode of affection of the limbs is not easy to explain. Invariably one arm and *both* legs were convulsed, the other arm escaping entirely. May it be connected with the more frequent simultaneous use of the legs than of the arms? It is to be observed that, in the right leg, spasm of the extensors predominated; while in the left leg that of the flexors was distinctly greater than that of the extensors.

Not less singular is the alternation which existed in the commencing spasm of the head. The spasm on the side chiefly affected (right) was preceded by transient contraction on the opposite (left) side, and even by a still earlier slight and passing affection on the right side. This preliminary alternation may, however, be compared to that which is seen not unfrequently at the close of an epileptic fit, in which the head is, at the commencement, turned to one side. In these cases, as the fit is passing off, it is common to see the head and eyes gradually turn towards the other side from which they turned at the commencement of the fit, and remain for a little while in this position after the fit has ceased. This deviation is not due to paralysis by exhaustion of the side first affected, but is the distinct result of the development of spasm on the opposite side. These two forms of alternate movements—the preliminary alternation which precedes the fit, and the subsequent alternation during its course—may be fairly compared. The latter is regarded by Dr. Hughlings Jackson as an instance of the influence exerted by each half of the brain upon the muscles of both sides of the body. The preliminary alternation I have described may be thus explained, or it may be regarded as an instance of reciprocal action between the two halves of the brain, related in a curious way to the development of the spasmodic process. The commencing evolution of the fit is accompanied by a similar process on the other side more easily manifesting itself than the severer "discharge" on the side chiefly in operation, but transient and ceasing, perhaps by inhibition, as the intenser action of that side is evolved.

The absence of any arterial spasm in the retina during the fit is a feature of considerable interest. It is not, however, surprising; for it accords with the entire absence of facial pallor. But it proves, at any rate, that a severe fit may occur under the circumstances of cerebral irritation without any evidence of coincident arterial spasm.

Queen Anne-street.

TWO CASES OF EXCISION OF CANCER OF THE BREAST BY SCISSORS-CUTTING UNDER ETHER SPRAY.

By THOMAS MOORE, F.R.C.S. Exam.

As the exhibition of a general anæsthetic during an operation always entails more or less risk to the life of the patient, and a corresponding degree of anxiety on the operator, any other means of producing insensibility to pain should be a matter of great interest to the profession. The use of our best local anæsthetic—freezing by ether spray—has, unfortunately, hitherto been almost impossible in operations where the incisions have to be carried to any depth, owing to the difficulty of cutting through the hardened tissues. In an article in The Lancet of Aug. 29th, 1874, Dr. B. W. Richardson asserted that he had overcome this difficulty, so far as operations on the breast at least were concerned, by the substitution of scissors for the knife; and he gave the history of two cases in which he had tried this method with unequivocal success. Since that time two patients have come under my care suffering from cancer of the breast, and at the same time from disease of the heart. As I made use of Dr. Richardson's operation in each of these cases, an account of my experiences with it may, perhaps, prove of interest, and will, I hope, induce others to make trial of it.

Case 1 was that of a maiden lady, aged forty-eight, from whose right breast I had, in July 1873, removed an adenocele without the aid of any anæsthetic. Several members of her family had died from cancer, but this tumour did not present features of malignancy. Neither she nor her friends would consent to its removal until it had become as large as a cocoa-nut, and a considerable surface of the skin over it had ulcerated. From this surface there had been several attacks of hæmorrhage, uncontrollable by styptics; and removal of the tumour appeared to afford the only hope of averting her speedy death. The heart's action was laboured and irregular, with a loud systolic murmur; the pulse was intermittent and feeble; and she had become almost childish from debility. Under these circumstances a general anæsthetic seemed out of the question, so I proceeded to operate without one, having previously exhibited brandy-and-water largely. The operation presented no special features of difficulty, but although the sensitiveness of the patient was considerably lessened by the state of almost dementia into which she had fallen, she yet suffered much pain. The after-progress of the case was satisfactory, the wound healed quickly, and the heart's action and the mental state both gradually improved.

When this operation was performed, a hard tumour, the size of a hazel-nut, could be felt in the other breast. This gradually increased in size, but my patient declined to have it removed until it had become as large as a turkey's egg, was very painful, and the skin over it was retracted. As the cardiac murmur and some irregularity of the pulse still persisted, I did not think it advisable to recommend a general anæsthetic; but at length (on the 19th of January last) induced her to allow me to operate by Dr. Richardson's method.

The ether spray was used by my partner, Mr. Cross, in accordance with the directions given by Dr. Richardson in the article referred to above. First a spray of common ether was directed over the breast for five minutes to chill it, and then a spray of anæsthetic ether for about three minutes until the part was frozen. I then cut the flaps with a pair of sharp-edged scissors, but I did not carry the incisions as low as the pectoral surface of the tumour. So far my patient did not complain of any pain. I then proceeded to use a pair of tooth-edged scissors to the deeper parts, but I found it impossible to raise the tumour from its attachments, partly because it was adherent to the pectoral muscle, but principally, I think, and as subsequent experience has shown me, because I had not made the first incisions deep enough. A considerable quantity of blood now welled up into the wound, and the freezing was consequently ineffectual. As my patient began to suffer much, and the rate of progress made by the tooth-edged scissors was slow, I was constrained to take up a scalpel and finish the operation as quickly as possible. The wound, which was dressed with oiled lint and cotton wool, subsequently healed fairly well.

Case 2.—A maiden lady, aged sixty-four, came on Sept. 9th, from a town fifty miles distant, to place herself under my care. She was suffering from a very hard scirrhus tumour of the left breast, rather larger than a turkey's egg, which she had first noticed eight months before, when it was as large as a walnut. There was no adhesion to the parts beneath, nor were there any glandular swellings, but there was some retraction of the skin over the centre of the tumour, and much lancinating pain. A niece had died from cancer six months before, but there was no history of the disease having shown itself in any other member of her family. She was thin and looked sallow, but her friends assured me that she had not altered in appearance for many years. The heart sounds were feeble, with a systolic murmur, and the pulse was very small and weak at the wrist. She informed me that her usual medical attendant had told her that she was suffering from heart disease.

As a general anæsthetic appeared to be contra-indicated, I determined to give Dr. Richardson's method another trial, in spite of my previous somewhat unfavourable experience of it, especially as I felt that most of the hæmorrhage and pain which occurred in the former case might have been avoided, if the parts had been more decidedly frozen, and if the incisions for making the flaps had been carried to their full depth at once.

On the 14th of September the operation was performed as follows:—First a spray of common ether was directed on to the breast for five minutes; then two sprays of anæsthetic ether were directed—the one by Mr. Cross, and the other by our assistant, Mr. Bayfield—on either side of the tumour for five more minutes, until the whole breast was frozen quite hard. I then, after making an angular cut in the skin at the outer margin of the tumour, carried the lower blade of the cutting-scissors deeply down through the breast until it appeared to rest upon the pectoral muscle. Then, keeping this blade as deep as possible, I easily cut the lower flap, about an inch from the tumour, with three or four strokes of the scissors. The upper flap was cut as easily. I next thrust the fingers and thumb of my left hand deep into the wound, and, grasping the tumour firmly, raised it as far as possible from the pectoral muscle. It was then easy to detach it with a few strokes of a pair of tooth-edged scissors. The operation so far was completed in less than three minutes from the time of the commencement of the first incision, and was attended with very little loss of blood. When the spray was withdrawn there was some hæmorrhage from three small vessels in the tissues which had been cut by the sharp-edged scissors, two of which were treated by torsion, and the other tied with silk, the ends of the ligature being cut off short. The edges of the wound were brought together by six sutures, and each of the twelve spots through which the needle was passed was previously separately frozen by the spray.

My patient, who declared beforehand that she was extremely sensitive to pain, gave very little indication of having felt any during the operation, and said afterwards that "it hurt her, but not a great deal." That her estimate of her extreme sensitiveness was correct (and indirectly the success of the anæsthetic) was proved by the fact that, during the introduction of one of the sutures through a part of the skin which had been accidentally insufficiently frozen, she cried out loudly, and declared that this "hurt her worse than all the rest put together."

The wound, which was dressed with oiled lint and cotton-wool, united by first intention, except in a spot where I had made a slight notch at the junction of two cuts of the scissors, and at the place of the first incision; but there never was more than just enough discharge to moisten the dressing, and that was entirely dried up by the sixteenth day. The patient was confined to her bed for one day, and to her bedroom and an adjoining sitting-room for a week.

The scissors used for making the first incisions were ordinary "elbow-scissors," with the blades inclined to the handles at about a third of a right angle; those for making the deeper incisions were tooth-edged and slightly curved "on the flat of the blade."

My experience of these operations has shown me that in using this method three things must be particularly attended to:—1. That the whole breast should be thoroughly frozen before the commencement of the operation, as otherwise hæmorrhage may afterwards prevent the freezing action of the spray. 2. That the incisions should be made at once to their full depth, as the difficulty of afterwards carrying them deeper, especially if there be hæmorrhage, is considerable. 3. That great care should be taken not to notch the skin, as doing so with scissors bruises as well as cuts it, and retards the healing process.

The success of my second operation, in the satisfaction it gave both to my patient and to myself, was such that I shall not hesitate to employ this method for the future for the excision of any tumour which does not require dissecting out from the subjacent tissues; for I was able to perform it about as quickly as I have performed similar operations with the knife under chloroform, and the wound healed as rapidly as could be desired.

Petersfield.

CASES OF DIABETES MELLITUS.

By M. CHARTERIS, M.D.,

PHYSICIAN AND LECTURER ON CLINICAL MEDICINE, GLASGOW ROYAL INFIRMARY.

While treating two cases of diabetes in my wards in the Royal Infirmary I became acquainted with the details of the following case from the personal narration of the patient.

A. B——, aged fifty-two, in an excellent business position in the city, in 1869 became aware of his having diabetes, and his usual medical attendant ordered him a diet consisting of beef and milk and dry toast. At that time he voided daily about 250 oz. of urine, with a specific gravity of 1044. He continued under that treatment for about a year and a half. The quantity varied little, and the specific gravity remained the same. The dietary became very irksome to him, and he had lost in weight about a stone and a half. A consulting physician who was called in recommended a purely skimmed-milk diet. This was adopted in 1872, and was continued for two years and three months. He drank thirteen pints or 260 oz. of milk daily, and passed about the same quantity of urine. Latterly he decreased the quantity of milk, because so much became nauseous to him, until it fell to 180 oz., the urine voided falling to 140 or 150 oz. The specific gravity of the urine under this treatment was 1020, but though low it was still loaded with sugar whenever it was tested. His weight had decreased to 11 st., and he was becoming despondent and extremely feeble when he made, as he terms it, his discovery about diabetes. He found that he commenced to wheeze when he breathed the cold air, and that it ceased on his return to a warm room. On putting his head below the bedclothes a slight perspiration came upon him, the saliva returned, and his tongue and mouth became moist, instead of dry, as formerly. When he withdrew his head again, and breathed in the open, his mouth and tongue again became dry and parched. This moistness and dryness of the mouth alternately occurring under the conditions mentioned having arrested his attention, the question arose in his mind, how could this moisture be obtained without remaining in bed? To accomplish this he put on a respirator, and also a knitted woollen cloth over both the respirator and his nostrils when in the house, or even in bed, and was careful in protecting the nostrils as well when he went out. He also began to practise breathing by the nostrils alone, and found that breathing exclusively in this manner day and night, except when engaged in conversation, was highly beneficial. Having perfected himself in respiring by the nostrils alone, he laid aside both the respirator and the cloth, only muffling himself carefully up when he went out at night or in frosty weather. He avoided going out at night as much as possible, and refrained from all cold diet or drink, invariably taking them warm. Under this treatment an amendment was apparent in less than fourteen days, and in less than a month it was very marked. The quantity of urine and sugar steadily decreased, while his weight increased, so that in six months he had regained his usual weight of 13½ st. The sugar at the same time disappeared from his urine, and he had acquired his usual health and spirits. He has continued in this favourable condition for the last two years, and in addition to the milk (heated) which still forms his staple article of diet, he is able to take some toasted bread and potatoes, and in addition a glass or two of wine at dinner. In fact, he lives like any other temperate man, and, being a very intelligent person, he has formed his theory in regard to the treatment, as already mentioned. Briefly expressed in his own words, it is this:—"Hitherto the attempt has been made to prevent production of sugar by giving a non-saccharine diet. This is no doubt perfectly correct, but in addition to this the treatment I adopted was intended to promote the consumption of sugar produced. This design of consuming sugar by breathing through the nostrils in warm weather or by means of a respirator, is that when the proper quantity of sugar has been consumed, the abnormal production will then cease. The aim of this treatment is to raise the blood-heat to its proper temperature, and to restore to the lungs their partially lost combustive power, and so enable them to consume as much secreted sugar as will maintain the blood at its proper temperature. When that purpose is accomplished the organs will regain their proper function, and the patient recover."

As previously observed, two cases of diabetes were in my wards in the Royal Infirmary, and I resolved to try the treatment mentioned upon them. The patients were informed of the object in view, and aided our efforts in every way.

CASE 1.—Patient, a single man, aged twenty-eight, was admitted passing 260 oz. of urine on the 14th of June. His disease had lasted twelve months, and various modes of treatment had been put in force and abandoned. The specific gravity of his urine in the morning was found to be 1035, and in the evening 1038, his weight being 10 st. 3 lb. In accordance with the principle mentioned in the foregoing case, he was ordered to wear a respirator during the day, and at night to cover the respirator and the nostrils with a knitted woollen cloth. The following was the dietary in this and the succeeding case:—Breakfast: Eggs, fish, one pint of tea, and biscuits. Dinner: Steak, biscuits, and cabbages. Supper: Tea, biscuits, and milk. Three pints of sweet milk were also taken during the day. The biscuits were prepared at my suggestion by Mr. Walker, biscuit manufacturer, of this city, who, after repeated trials, made a biscuit palatable to the taste, and possessing no, or at least only a very small quantity of, starch in its composition. On the 18th of June, 1875, the patient stated that he perspired freely, and that, on awaking, his mouth was not parched but moist. The quantity of urine passed, which was carefully ascertained every day, was as follows on the dates mentioned.

	Total amount in ounces.	Specific gravity, 10 A.M.	Specific gravity, 10 P.M.	Weight.
June 18th	248	1040	1033	—
,, 22nd	236	1037	1031	10st. 0lb.
,, 26th	230	1035	1030	—
,, 30th	218	1033	1029	9st. 9lb.
June 3rd	212	1039	1030	9st. 11lb.
,, 7th	200	1033	1030	—
,, 11th	168	1037	1034	9st. 10lb.
,, 18th	150	1037	1034	—
,, 22nd	120	1032	1032	10st. 0lb.
,, 26th	100	1034	1033	—

After this, he went to the Seaside Home at Dunoon, and subsequently resumed his occupation in a distant part of the county, and was able satisfactorily to do so according to the account of his friends.

CASE 2.—The patient was a married man of healthy parents, and employed as a railway pointsman in a country district. He observed that he was passing more than an average amount of urine twelve months ago, but thought nothing of it until he found his sexual powers entirely gone. His urine was tested, and gave abundant evidence of its saccharine properties. On admission the quantity passed in twenty-four hours was 330 ounces. The patient complained of great thirst, gradually increasing weakness, pain in his loins, and a numbness affecting especially his fingers and toes. With every anxiety to do what he was told, he found it extremely difficult to refrain from drinking water or any other liquid. A similar course of treatment as in the other case was adopted with the following results:—

Date.	Urine in ounces.	Sp. gr.	Sugar per ounce.	Sugar per diem.	Weight.
April 25th	330	1034	34	11·220	9st. 5lb.
May 17th	180	1038	34	6·120	
,, 18th	190	1035	35	6·650	
,, 19th	200	1040	40	8·000	
,, 20th	200	1036	30	6·000	10st. 2lb.
,, 22nd	200	1036	34	6·800*	
,, 24th	170	1032	30	5·100	
,, 26th	130	1032	32	4·800	9st. 12lb.
,, 28th†	140	1033	32	4·480	
June 1st	135	1032	32	4·320	
,, 3rd	130	1031	31	4·030	
,, 4th	130	1040	37·53	4·880‡

,, 9th	120	1033	31·5	3·780	
,, 12th	120	1027	28	3·360	
,, 15th	100	1036	32	3·200	
,, 17th	100	1031	30	3·000	
,, 19th	100	1036	33	3·630	

* Urates 1·05 per cent. † Went home for three days.
‡ Estimated by Dr. Milne. § Urates ·95 per cent.

I saw the patient again on 23rd Sept. He was employed as a railway porter. His weight was 11 st. The specific gravity of the urine was 1032, and the quantity voided in the twenty-four hours was 120 ounces. The usual tests indicate the presence of sugar.

Remarks.—I have not hesitated to give the details of these cases to the profession. The mode of treatment is simple, and in its originator's hands has been attended with the most beneficial results. In the two cases I had good also accrued, though not to the same extent. The publication of the cases will, I trust, stimulate others to give it a fair trial and record the results. It has one advantage—it cannot possibly do harm.

Glasgow.

NOTES OF FIVE CASES OF ARROW-WOUNDS (RECEIVED IN THE SOUTH SEA ISLANDS), TWO FOLLOWED BY TETANUS AND DEATH.

BY SURGEON ALFRED CORRIE, R.N.

(*Continued from p. 620.*)

CASE 2.—Edward R——, aged eighteen, seaman. This man, when on shore at Santa Cruz Island, received a punctured wound of left arm, about the insertion of the deltoid muscle, from an arrow (supposed to be poisoned, as before named), at a distance of some seven or eight yards. A little hæmorrhage took place at the time. The wound was at once sucked by a man near.

Fifteen minutes after the accident the man was seen by the medical officers on board. The wound was enlarged and washed, carbolic acid and glycerine were injected, and a stimulant in the form of brandy-and-water administered. The patient received the injury at 3.30 P.M. on August 12th, 1875. At 8 P.M. he complained of some pain about the part, a little headache, but nothing more. The wound was dressed.

Aug. 13th.—Slept but little during the night; no sickness, chills, or headache; some pain, swelling, and inflammation in the neighbourhood of the wound; tongue clean; bowels regular. Temperature 99·8°; pulse 80. Ordered linseed-meal poultice.—8 P.M.: Vomited twice after meals; more pain and swelling at the seat of wound. Continue poultice. Temperature 99·8°; pulse 88.

14th.—Passed a good night; slept well; felt rather faint when he awoke this morning; nasty taste in mouth; less pain about wound; no vomiting or headache; tongue clean. Temperature 99·4°; pulse 100.—8 P.M.: Taken food well;

wound still very painful; continue poultice. Temperature 98·4°; pulse 80.

15th.—Slept well; wound not looking so healthy; no sickness, headache, or rigors; taking food tolerably well; continue poultice. Temperature 98·4°; pulse 84.—8 P.M.: No change perceived in patient. Temperature 98·4°; pulse 72.

16th.—Passed a good night; some discharge from wound; bowels regular; continue poultice. Temperature 98·4°; pulse 80.—8 P.M.: Complains of more pain about wound; some swelling above and below, with inflammation around; not taken food very well to-day. Temperature 98·4°; pulse 68.

17th.—Slept well; wound painful; pain shooting up and down arm; no enlargement of glands in axilla; wound was laid open to let out some pus; tongue clean; continue poultice. Temperature 98·8°; pulse 80.—8 P.M.: During the day suffered from a severe rigor; some headache, thirst, anorexia, and general constitutional disturbance. Temperature 102°; pulse 112. Forty-five minims of solution of hydrochlorate of morphia ordered at bedtime.

18th.—Slept but little during the night; the least noise awoke him and made his arm jerk, an unhealthy discharge coming from the wound; part very painful, much swelling and hardness about it; skin hot, face flushed, thirst, no inclination for food, bowels confined, headache, and general feverishness. Put under chloroform, and a free incision made; much unhealthy pus let out; at the bottom of the wound, which was found to be very deep, nearly to the bone, a small piece of rough bone was discovered belonging to the tip of the arrow. It was removed, and the wound dressed. Temperature 100°; pulse 88. An enema of turpentine given; beef-tea, four ounces of wine, &c.—8 P.M.: Very restless during the day, unable to sleep in spite of hypodermic injections of morphia; the least noise or movement caused much spasm of the arm; taken but little food, drank much, vomited several times during the day; bowels not opened by enema; tongue coated with a white fur; headache. Temperature 100·6°; pulse 100. Ordered an injection of morphia.

19th.—Very restless during the night; if he fell off to sleep he was awoke with spasms in his arm. Complains of stiffness about the jaws and neck, unable to open mouth widely or protrude tongue freely, which is thickly coated with a brownish fur; unable to swallow solids, and some difficulty in taking fluids; pain about dorsal and cervical regions; slight spasmodic action of muscles of lower extremities. Temperature 99·4°; pulse 100. Suffers much from thirst; bowels constipated; passing water freely; occasional vomiting. The wound is not very painful; much stiffness and thickening about it; an unhealthy discharge, but not much of it. Redressed; enema of beef-tea, port wine, &c., given, and injections of morphia every five or six hours.—8 P.M.: Temperature 104°; pulse 120. Has slept but little during the day; suffered much from constant spasms in the arm; breathing short and hurried; difficulty in getting his breath at times; much distress in swallowing; able to take a little nourishment in small quantities; convulsions becoming more frequent and severe. Large doses of chloral hydrate were given per enema, but failed to promote sleep.

Between 12.30 and 3.30 A.M. of the 20th he suffered from two or three violent spasms. At 3.30 the first one came on, of the following nature:—Jaws firmly fixed; head and neck thrown back by the violent contraction of the muscles; body bent backwards to form almost a complete arch (opisthotonos); muscles rigid, felt like a piece of hard board; respiration hurried and laborious; pulse rapid, irregular, and fluttering at first, gradually getting smaller and smaller; countenance pale, anxious, and greatly disfigured, presenting a most pitiable appearance. The spasm lasted but a few minutes, when the patient fell back breathless and pulseless, and death closed the scene.

He suffered from slight delirium only a few hours before death; before that all his mental faculties were perfectly clear. He never lost control over bowels and bladder. The great absence of sleep was very marked in this case in spite of constant and large doses of chloral and morphia.

He died on the eighth day of the accident and some forty to forty-five hours after tetanus set in. Death appeared to take place from suffocation, in conjunction with extreme exhaustion.

(*To be concluded.*)

ON THE RAPID RELIEF OF NEURALGIC PAIN.

By SPENCER THOMSON, M.D.

Amidst the various improved methods of treatment which have become established in the practice of medicine during the last twenty years none are more strikingly beneficial than those which enable us to subdue, with tolerable certainty and celerity, the agony of neuralgic pain, or of what, for want of a better word, or perhaps deeper knowledge, we call neuralgia. It needs not but to refer to works on Practice of Medicine, published not so long since, to see how little comparatively in the way of relief could be afforded during the paroxysm. For this external applications were chiefly trusted to, in the hope, often vain, that they might in some degree palliate the suffering, until the disease itself had been conquered after a longer or shorter interval by the not always certain quinine, carbonate of iron, arsenic, or other antiperiodics. All this is greatly altered, and I think we may now congratulate ourselves that a large number of cases of so-called neuralgia may be quickly, either permanently cured by the relieving remedy, such as phosphorus, or relieved, until such time as specially curative agents, or curative general treatment, have removed the tendency to the recurrence of the pain. As one of the newest of the remedies, I would first allude to one which is much too slowly making its way into the domain of practical therapeutics; I allude to the recently introduced "tincture of Gelseminum sempervirens," or yellow jasmine. In my presidential address delivered before the South-Western Branch of the British Medical Association, in 1874, I alluded to this remedy as having proved very successful in my hands, and in a paper I read this year at the Plymouth meeting I was able to state how fully it had fulfilled my expectations during the twelve months that had elapsed since my former notice of it. Directly or indirectly it had been used by me, or by my authority, in at least forty cases to which it was applicable, and with almost constant success. In using the word "applicable," I do so in accordance with my own experience that the remedial power of the gelseminum seems confined to those branches of the trifacial nerve supplying the upper and lower jaw, more particularly the latter, and more especially when in either jaw the pain is most directly referred to the teeth or alveoli; indeed, I can scarcely recall an instance of the above in which relief was not speedily and thoroughly given. The usual expression of the patient has been, "It acted like a charm." In illustration I give one case.

On Sunday afternoon, June 20th, the housemaid of a friend, a retired medical man, came to me with a note from her master, stating that she had been suffering from agonising pain, of what was thought to be toothache, for six-and-thirty hours. Nothing gave relief, and no dentist could be found to remove the only suspicious tooth. I sent her home with a bottle of gelseminum tincture, which I keep for home use, desiring that she should have twenty minims at once, and twenty more within two hours if not relieved. Her master sent me a note in which he stated that the patient had experienced immediate relief.

The above case was not one of distinct toothache, but rather of pain affecting the alveoli generally of the affected jaw. Still, even in toothache seated in one tooth, the remedy gives relief, provided, of course, abscess is not actually in formation. I have observed above, that, according to my own experience, the beneficial effect of the gelseminum is confined to neuralgic pain of jaws generally, and of teeth and alveoli more particularly; and a short paper, in the *Practitioner* for August 1875, by Dr. Gamgee, of Birmingham, supports the view. In September, 1875, there were published some cases of other neuralgias, even one of sciatica, in which cure was effected, under the care of Dr. A. Jurasz, of Heidelberg. Should the remedy indeed prove generally useful in neuralgia, it will of course give it additional value in our materia medica, but at present it has gained no such position, either according to my experience, or, as far as I can learn, that of most others.

In the notices I have met with on the use of the gelseminum, the doses quoted seem all too small. I now almost invariably prescribe, for an adult, twenty minims of the tincture as a first dose, to be repeated any time after an hour and a half if relief is not given. I have rarely had to order a third dose, and I have never found any inconvenience result from the larger doses. In one instance, a gentleman who, unadvisedly, took thirty minims at once, and immediately afterwards went out driving, told me he experienced for an hour or two some uncertainty of vision when guiding his horse. A severe attack of neuralgia of the jaw was, however, cured by the one dose, and did not return. One young lady, to whom I gave two twenty-minim doses during the night for a severe neuralgic attack, more particularly of the temporo-auricular branch of the inferior maxillary nerve, complained of a little heaviness next morning. In this case little if any relief was given; but the teeth and alveoli were not implicated, and it is only when these are that complete relief can be calculated on according to my own experience.* The above case was at once cured by the solution of phosphorus, to be noted presently.

As further illustration, I may mention the case of a lady who was under my care last winter for local disorder, but who also suffered severely from neuralgia, attacking at one time the lower jaw and at another the orbital and frontal nerves. The gelseminum invariably relieves the maxillary pain, but has no effect whatever over the frontal. For this, however, for a long time at least, I found a most efficient remedy in phosphorus, given in the liquid form. The form I have used is that given by Ashburton Thompson in the *Practitioner* for Oct. 1873. It is taken without repugnance, rarely causing disorder of the stomach or eructation, and, what is most important, keeping perfectly. One of the cases I have mentioned was treated with a preparation which had been made four months at least. I have found a twenty-minim dose, equal to one thirty-sixth of a grain of phosphorus, give rapid relief, and, what is important, independent of locality.

Even phosphorus, however, we know, will, after a time, lose its power in some obstinate cases of neuralgia—at all events its power of giving rapid relief; and then it is that the invaluable hypodermic administration of morphia comes to our aid. This remedy, and its mode of administration, are too well known to require comment here; but it is far from being as generally employed as it ought to be. This, perhaps, is due to various causes, but of these I believe the principal are—the means of administration not being always readily available, and the objection of patients to the pain consequent upon the use of coarsely constructed instruments. The first of these objections I have endeavoured to meet by the use of a very portable hypodermic apparatus, enclosed in a metallic case, with ample supply of needles, and the great desideratum, an always moist and efficient piston; and by always carrying a supply of Sansom's gelatine discs, as made by Messrs. Savory and Moore. The second objection is met by the use of very fine steel needles only, as made for me by Mr. Hawksley, of Oxford-street. The discs, which contain one-sixth of morphia in each, are a very safe and efficient dose for most cases, although in some it may be well to begin with a less amount, and in many it may be advisable to increase the dose considerably—half a grain, or even double that amount. I may here give it as the result of a very large experience in the hypodermic administration of morphia, that concentrated solutions are the reverse of advantageous. In the first place, they are not so safe as the more dilute; and, in the second, they do not act so quickly and agreeably. The usual strength I employ is one grain of hydrochlorate of morphia in forty minims of water, rarely in thirty. The slight increase of bulk is of no consequence, and in administrations I can count by the thousand I have never seen the slightest bad consequence, in the way of abscess or otherwise, result to the patient.

With morphia, and occasionally—but only occasionally—atropia, to use hypodermically; with phosphorus in solution; with gelseminum, aided at times by the ordinary external appliances, such as heat, or freezing if need be; aconite, and chloroform,—one ought to feel fully prepared to meet and subdue at the time most cases of neuralgic pain, and, indeed, of pain generally.

Of course the after-treatment, which is to obviate the recurrence of the disease, does not fall within the scope of this paper. This paper would not, however, be complete without some notice of other remedies which have lately come to the front in the treatment of neuralgia. Of these the Calabar bean, as advocated by Dr. Munro, deserves a thorough trial. In one case only have I used the discs introduced under the eyelid, but in that a severe frontal neuralgia was certainly alleviated; having other remedies in which I placed confidence, I probably did not persevere sufficiently. Fleming's tincture of aconite in one minim doses repeated at intervals of an hour, I have found relieve severe neuralgia of the eyeball, and the tincture of actæa racemosa very useful when pain in the same situation seemed the result of a general rheumatic condition.

The object of this paper, however, is not to enumerate the long list of remedies, internal and external, which have been used in the treatment of neuralgia—a list which shows how urgently a successful treatment was needed,—but rather to direct attention to the remedies I have dwelt upon. I cannot, however, close without adverting to Dr. Evans's paper in the *Practitioner* for September, 1875, upon "Nitrite of Amyl in Facial Neuralgia." His account of the relief afforded in the anæmic cases would point to this new agent as one requiring careful trial, hopeful of results.

KING'S COLLEGE HOSPITAL.

OPERATIVE INTERFERENCE IN CASES OF CLEFT PALATE.

(By Sir WILLIAM FERGUSSON, Bart.)

AT p. 784, vol. ii. 1873, of this journal we described the details of operative procedure that had just been adopted by Sir William Fergusson for the closure of the cleft in the hard palate, in place of the Langenbeck operation. Although the operation had suggested itself to the mind of Sir William quite independently, and was thought at the time to be original, he subsequently discovered that a similar device had been recommended by Dieffenbach, although there was no evidence to show that that surgeon ever carried it into effect. Since the first notice, we have at various times published the notes of several cases in which the operation has been practised, and announced two or three modifications of the operation as originally performed. During the past eighteen months Sir William has operated in this manner in a large number of cases, both in hospital and in private practice, some of which would have been quite beyond the reach of the ordinary operation. Instead of stripping muco-periosteal flaps from off the hard palate, after the plan of Mr. Avery and Langenbeck, and bringing them together in the middle line so as to close the opening, Sir William Fergusson detaches a piece of bone on each side of the cleft, and then forces the bone, periosteum, and mucous membrane towards the middle line and fixes them there. The steps of the operation are briefly as follows:—The patient is first put under the influence of chloroform, followed or not by ether, and the jaws kept wide apart by means of a gag. The levatores palati and the palato-pharyngei muscles are then divided by means of a rectangular knife. After this the mucous membrane is pared from the edges of the cleft, care being taken to remove mucous membrane only. Two apertures are then made, with an awl, through the hard palate on each side of the fissure and close to the edge, the holes on one side exactly corresponding with those on the opposite side. A fine silk suture is then passed from the mouth through each of the holes on one side, across the floor of the nasal cavity, and made to enter the mouth again through the corresponding holes of the opposite side. An incision from before backwards is then made through the mucous membrane and periosteum on each side, just outside the sutures. The operator, by means of a small chisel, next cuts through the hard palate in the site of these incisions. The two pieces of bone thus detached are then forced towards the middle line, and fixed by means of the sutures. Where the hard and soft palates are operated on at the same time, Sir William usually puts two sutures into the hard palate, and three in the soft, and fixes them in the following order:—Reckoning from before backwards, the second suture in the hard palate is first tied, then the three sutures in the soft palate, and last of all the foremost suture in the hard palate. When everything is thus made firm, lint is placed into the apertures in the hard palate made with the chisel, and allowed to remain two, three, or even four days. The lint is then removed, the sutures taken out, and the parts left to recover. It is interesting to note that the hard palate soon becomes consolidated, so that in a few months it often seems to be bony throughout; or, if not bony, to be at least made up of very dense fibrous tissue.

---

* That gelseminum has not yet received the attention it merits is evident from the difficulty of procuring it. During the meeting in Edinburgh in August, I inquired for it in vain at most of the principal chemists.

On Saturday last we saw the operation as described above performed on a man aged about thirty, whose case had previously been considered almost too bad for any surgical interference, the patient having for many years worn an obturator. On the same day we had the opportunity of observing the excellent results obtained in three or four other cases that had been operated on within the last four or five weeks, and are still in the hospital.

WESTMINSTER HOSPITAL.

SURGICAL CASES AND NOTES.

There are at the present time a number of interesting cases in Mr. Cowell's wards at this hospital. Among the cases in the Accident wards are two men who were injured at the same time by a boiler explosion. One sustained a compound fracture of the tibia and simple fracture of the fibula, and the other a severe contusion of the back by the forcing open of a door. The right half of the back seems to have received the full force of the flat margin of the door, and the skin covering its whole surface is black from ecchymosis. Over the lumbar vertebræ and extending over the left loin there was an enormous thrombus. No damage to the spine was apparent beyond some contusion, and the only symptoms were, for the first twenty-four hours, retention of urine, and for about three days some numbness of the right leg.

In St. Matthew ward we noticed a good, nearly healed stump after amputation of the thigh. The patient, a man about twenty-three years of age, had been the subject of strumous degeneration of the knee-joint, with abscesses burrowing in all directions; and the case had been an unfavourable one for resection of the joint. The disease was of long standing, the joint being thoroughly disorganised, and some of the cartilage at the back of the patella had been removed. The patient has made an uninterrupted recovery, notwithstanding that the walls of abscesses entered largely into the surfaces of the flaps. A patient in an adjoining bed is a good instance of the rapidity with which an ulcer often heals after transplantation of skin.

In St. Mark's ward we saw an old man who had undergone amputation of the leg a few days ago. His stump, which so far looked remarkably well, had no dressing of any kind—a condition in marked contrast to the thigh-stump before mentioned. Mr. Cowell remarked that he observed no fixed rule with regard to dressings. In some he preferred none, in others he thought the support and protection of dressings of service, and in a few cases he had adopted Professor Lister's antiseptic plan of dressing with great advantage. In this case he had discarded dressings in order that any occurrence of hæmorrhage might be at once known by constant observation of the stump, and that any dragging of the flap upon the prominent end of the tibia might be avoided by the careful adjustment of a small pillow beneath the end of the stump; and he was further anxious to avoid the lowering of the vitality of the margins of the flaps which is sometimes induced by a continuation of the use of cold wet dressings. The man is in a low condition of health, and a previous amputation of the great toe, with its metatarsal bone, had been followed by considerable sloughing and subsequent mischief.

In Holland ward there is a very good example of a menstrual ulcer of the leg. The patient is about twenty-three. The uterus is very imperfectly developed, and she has always menstruated scantily; but during the last four years the discharge has entirely ceased from the uterus, and the function has since always been performed through the ulcer. Ten months ago Mr. Cowell had a similar ulcer under his care, which rapidly healed on the re-establishment of the healthy function. In this ward there is also a case of resection of the knee in a little girl.

In Percy ward is a patient from whom Mr. Cowell removed an enormous adenoid tumour of the right breast about four months ago. The growth, which was nearly as large as the patient's head, presented some of the characteristics of malignant growth, and the skin was much implicated. Nearly the whole of the skin had to be removed with the tumour, two triangular flaps only being saved from the upper part of the mass for the purpose of affording a covering for the wound. A section of the growth showed it to be of an adenoid character. The greater part of the wound healed. Nodules of new growth, however, soon appeared in the flaps above mentioned, and speedily coalesced and formed large round lobes. Ulceration ensued, with considerable discharge. The growths were subsequently dressed with a chloride of zinc and opium paste, by means of which the growths have been almost entirely destroyed, and little or no discharge remains. The patient is, however, in a very weak state. The return growths have shown a remarkable tendency to exfoliate and come away.

Another case is that of a woman who is just convalescent from necrosis of the whole shaft of the tibia. Mr. Cowell removed it by laying two cloacæ into one and dividing the large sequestrum in half with a strong pair of bone forceps; the anterior half of the bone was divided first, and the upper and lower portions were separately withdrawn from the wound; the posterior half was then treated in the same way, and all the necrosed bone removed. The large cavity thus left has gradually filled up and contracted, and a good strong tibia is the result.

In this ward there are three cases of hip disease in children. One, in the early stage, has been treated by extension with a weight for two months, and is now convalescent. Another had adhesions, with the limb fixed in a flexed position; under chloroform the adhesions were separated, a long splint was applied, and the patient has made an uninterrupted recovery. In a third case there are some complications; some disease of the pelvis accompanies the hip mischief. A large abscess of the thigh was first emptied with the aspirator, and subsequently two free openings were made, one above and the other below, under the carbolic spray. Drainage-tubes were introduced, and the dressings were daily renewed on the antiseptic plan, and with the best result. The case is, however, one in which there is not much to be done.

In Queen Anne ward there is a case of fracture of the olecranon; also a case of a child who was run over, in whom the pubic bones were separated three or four inches, with some laceration of the vagina. The right thigh was the seat of a contused wound, extending from Poupart's ligament, winding round the inner side of the thigh, and terminating below the popliteal space. This wound was followed by a good deal of sloughing. A catheter was passed, and it was found that, fortunately, the bladder had escaped injury. The pubic bones were gently pressed together, the wound dressed, and the legs kept together by a couple of sand-bags. Although this at first appeared to be a very serious case, the child made an uninterrupted recovery. The child is now made an out-patient, but the wound is not yet healed in the region of the popliteal space, and a splint will be required for some time to prevent contraction of the knee.

HÔPITAL ST. ANTOINE.

CASES OF SYPHILITIC HEADACHE AND NEURALGIA CURED BY CALOMEL IN SMALL AND REPEATED DOSES.

(Under the care of Dr. Peter.)

In syphilitic headache, which is always so painful and often produces obstinate insomnia, as well as in neuralgia of venereal origin, Trousseau used to prescribe calomel in very small and repeated doses; for instance, one centigramme (or about one-sixth of a grain) a day, divided into ten doses, administered at one hour's interval, so that the patient would take one milligramme only (or about one-sixtieth of a grain) every hour.

Dr. Peter, following Trousseau's example, uses this drug in similar cases as well as in doubtful ones, in which it has the excellent effect of speedily determining the nature of the disease.

Dr. Peter often quotes the instance of a young girl who entered Trousseau's wards for a severe facial neuralgia. For more than fifteen nights the patient had not slept, on account of the intensity of the nocturnal pains. The illustrious "clinician" noticed on the girl's temple the presence of a very small tumour, painful on pressure, and which he thought must be of syphilitic origin. Possibly the tumour rested on some filament of the temporo-facial nerve and produced irritation of it. Anyhow, he resolved to prescribe calomel immediately in doses as above described. The very same night the young woman slept four hours. The next night was attended by perfect sleep, and the pain disappeared entirely on the third day, though the size of the tumour had not much decreased.

Amongst other cases treated in like manner by Dr. Peter, the following are worthy of being noted.

A woman, aged twenty-three, was admitted on October 9th, 1874, for various syphilitic manifestations, large *plats muqueux* of the vulva and anus, a general papulo-squamous syphilitic eruption, &c. For these lesions the patient had already been put under a course of protoiodide of mercury before entering the hospital. But her chief complaint was a most violent nocturnal headache, beginning at 4 P.M. and lasting till 4 A.M., and which completely deprived her of sleep. Moreover, she had fever, and complained of intense pain along the nerves of the left arm and in the brachial plexus of the same side. On October 10th, instead of continuing the use of the protoiodide of mercury, as had been prescribed in town, Dr. Peter ordered one centigramme of calomel in ten doses, each to be given at an hour's interval. The next day (the 11th) the patient's report was that she had suffered less during the night. The headache commenced only at 6 P.M., and left her at 2 A.M., after which time she was able to sleep. The pain in the arm had been the same. In the night of October 11th-12th the headache almost completely disappeared. It commenced very slightly at 7 P.M., and was so slight that the patient was able to sleep almost the whole night. The fever had also ceased. The calomel was then discontinued, nevertheless the night of October 12th-13th was excellent. The headache went off entirely, and the pain in the arm had diminished considerably. From that moment the classic treatment of syphilis—viz., the protoiodide of mercury—was resumed in order to combat the other syphilitic manifestations.

In another woman, who entered Dr. Peter's wards on the 20th of February this year, the syphilitic headache had been going on for nearly a month. It had been general at first, but after a fortnight became confined to the left side of the head. As usual, the pain was much more intense at night than in the day, and prevented sleep. Together with this headache, the patient complained of an intense pain in the right side, and indeed it was for this latter ailment that the patient had sought admittance into the hospital. Dr. Peter stated that it was seated in the situation of the chondro-costal articulation of the left side, which was slightly tumefied. Moreover, the patient had syphilitic roseola. On Feb. 22nd ten milligrammes of calomel were prescribed, but through some mistake only two were given. The patient suffered much from the head during the night. On the 23rd ten doses were administered. The headache disappeared almost completely, and the patient slept for ten hours. On the 24th, the stitch in the side, which had been already less painful two days before, when only two doses were taken, diminished to such an extent that it required rather strong pressure to produce any pain. On the 25th the ten doses were again forgotten, and the patient did not sleep so well as on the previous night. The sleep was, however, better than at first, and the headache less intense than before the calomel was used. The ten doses were given this day, and the patient slept from 8 P.M. till midnight. From that hour she only got sleep in snatches, but without having any pain in the head; the pain in the side had by this time completely disappeared. On the 27th the general treatment of syphilis with a syrup containing iodide of mercury and iodide of potassium was commenced. The headache was only felt two hours in the nights of the 27th and 28th, and afterwards entirely ceased.

The remarkable features of this mode of treatment, says Dr. Peter, are—first, the rapidity of its action; next, the fact that it is successful in cases where the really specific treatment of syphilis fails. It constitutes, in a manner, *the* medicine of nocturnal syphilitic pain; but cannot replace the other plan of treatment for other syphilitic manifestations. Its use is indicated whenever nocturnal pain is very intense and interferes with sleep. It diminishes pain and its consequences the very first night it is given, and generally extinguishes suffering by the second night. The treatment may be carried on for three days, and that period of time is almost always enough for its success. If, however, the desired result has not been obtained, it ought then to be suspended for one or two days, so as to prevent salivation; and it can be resumed afterwards for two days successively, in which case Dr. Peter has never seen it fail.

Dr. Peter thinks that this plan of treatment is thus efficacious because—first, the drug is mercury; and, secondly, the absorption of these very small doses is exceedingly rapid, and the repetition of the action takes place every hour. Whatever the explanation may be, adds Dr. Peter, it is to Trousseau that he is indebted for the idea of using calomel in this manner, and to him belongs all the credit.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

THE ordinary meeting of this Society was held on the 2nd inst., Mr. George Pollock, the President, occupying the chair. Several specimens of interest were shown, and at the close of the meeting the list was far from exhausted. Among the more striking specimens were examples of visceral syphilis, contributed by Mr. Gould and Dr. Greenfield; a case of cancer of both male breasts, by Mr. Wagstaffe, accompanied by full statistical details; calculi of cystin, by Mr. Heath; and a rare form of carcinoma, by Dr. Fagge.

During the evening Dr. H. J. Philpot was elected a member of the Society.

The proceedings commenced by Dr. COUPLAND relating briefly the results of his microscopical examination of the specimens from a case of Infantile Syphilis shown by him at the last meeting. In the heart there occurred abundant infiltration of small round cells imbedded in a structureless matrix, and separating bundles of muscular fibres, many of which were atrophied. The infiltration was most marked around the vessels. In the lung the gummatous nodule was composed of a reticulum of fibrous tissue, with round cells in its meshes, while at the margins of the growth there was an infiltration of the alveolar wall, causing compression of the air-cells. There was periarterial and peribronchial thickening. In the liver, the central parts of the gumma presented similar characters to that in the lung, and at the margins of the mass there was a similar infiltration of round cells between the hepatic cells, and in the portal canals. Lastly, he had examined the kidney, which presented a normal appearance to the naked eye, and had found essentially the same change in that organ—viz., a massing of nuclei around vessels and between the tubules in the cortical portion of the gland; in fact, an interstitial nephritis.

Mr. GOULD showed a specimen of Syphilitic Disease of the Heart, taken from the body of a man forty years of age, who had died suddenly. There was found a large pulmonary apoplexy on the left side, but no other lesion save in the heart, where the anterior wall of the right ventricle was occupied by greyish-white tissue extending as far as the ventricular septum, and invading the wall of the right auricle. The left ventricle was healthy. Microscopically there was an infiltration of small round cells between the muscular bundles on the surface of the heart, while the centre of the mass was wholly composed of fine fibrous tissue forming a reticulum containing round cells. There was no history obtained, except that for some time past the patient had suffered from cardiac dyspnœa; and Mr. Gould remarked that the characters of the growth were those usually described as syphilitic.

Dr. Greenfield showed a specimen of Syphilitic Pneumonia, interesting chiefly on account of its bearing on the case shown by Dr. Coupland. The specimen, of which also microscopic sections and drawings were exhibited, was removed from the body of a child twelve months old, who died in the out-patient room at St. Thomas's Hospital. There was no history of acute illness. The child had suffered from cough for some time. The history altogether was scanty. At the post-mortem examination the whole of the right lung was found to be solid, extremely dense, and tough; the pleura was slightly inflamed, but free from old thickening; the bronchi, slightly inflamed, contained mucopurulent fluid; the cut surface of the lung was of a yellowish-white colour, and on close examination the tissue appeared to be everywhere interspersed with fibrous bands of varying thickness. Microscopically a great part of the lung structure was found to be taken up by a new growth, consisting of an enormous infiltration by a small-celled growth around the vessels, and of vascular fibrous tissue in various stages of development, producing thickening of the walls of the air-cells. The air-cells were compressed and in many places destroyed, but their epithelium was in great measure normal. In some places there was catarrhal or fibrinous exudation into the air-cells. Dr. Greenfield remarked that the condition of the lung resembled that described under the name of syphilitic pneumonia or diffused syphilitic cirrhosis, when occurring in newly-born children; and from the history of the case, the age of the disease, and the striking resemblance of the new growth to the infiltration round the gumma in Dr. Coupland's case, he was inclined to believe it to be syphilitic. At any rate he would be glad to know whether there were any distinctions between the clinical or pathological characters of syphilitic infiltration and chronic pneumonia or cirrhosis.—Dr. Goodhart drew attention to two specimens which he had brought forward about two years ago: the one he had styled "syphilitic pneumonia" was associated with other evidence of syphilis; the other presenting much the same characters as those described by Dr. Greenfield, occurred in a boy after fracture of the ribs.—Dr. Green said that no doubt the changes described by Drs. Greenfield and Coupland were such as are met with in the lungs of syphilitic infants, but it was open to question as to how far the infiltration described was peculiar to syphilis. The change was simply that due to a chronic inflammatory process, and collateral evidence was necessary before ascribing the change to syphilis. He alluded to cases which he had seen.—Dr. Greenfield inquired whether in these cases the change was general throughout the lung, or had occurred only in patches, and whether there was any evidence of the disease having originated in an acute pneumonia?—Dr. Green replied that in such cases—whether "cirrhosis" or chronic pneumonia arising out of acute change—there was no histological character distinctive of the one or other process.

Mr. Wagstaffe exhibited a male patient who had been the subject of Cancer in both Breasts. In March, 1874, the man came for advice, having a large nodular growth, implicating the skin, in each breast, and induration with enlargement of the lymphatic glands in the left axilla. Both breasts were removed, and the patient made a good recovery. Subsequently a portion of the larger masses in the left axilla was removed. There has been no indication of recurrence. Dr. Creighton had examined the tumours, which were examples of true scirrhus, and stated in his report that the acini of the mammary gland were well marked, in some places a germination of epithelium presenting a ridged and fenestrated appearance. The alveoli were formed by bands of fibrous tissue, including an adenoid network, an appearance favouring the view held by Waldeyer as to the perivascular growth of mammary tumours. The softer parts of the larger tumour were composed of masses of cells in places caseous, but doubtless developed from the acini of the gland. Mr. Wagstaffe then gave an interesting statistical account of cancer in the male breast. He had collected 51 cases, including 42 recorded by Mr. Milton in the 40th volume of the Medico-Chirurgical Transactions. The right breast was about as often affected as the left. The age of the subjects varied from twenty-five to eighty, and the duration of the disease from one to eight years. In the majority the adjacent tissues were infiltrated, and although there was often decided constitutional infection, yet some benefit was derived from operation. Among the successful cases he mentioned one operated on by Mr. Cæsar Hawkins, the patient surviving six years; and one recorded by Warren of eleven years' duration. In the Paris Register, out of 9118 cases of cancer, only five occurred in the male breast. The present case was further unique in the implication of both breasts, and that at so short an interval from one another.

Mr. Croft exhibited a specimen of Sarcoma of the Breast also removed from a male subject. The patient was fifty-two years of age, and the tumour, which was of rapid growth, projected in a series of three prominences from the breast; the upper part of it was soft and elastic, the rest being firm; the skin was involved. On removal it proved to be a spindle-celled sarcoma, confirming the diagnosis of its nature which Mr. Croft had first adopted. The patient did not rally from the operation, and died eight days afterwards.—Mr. Maunder referred Mr. Wagstaffe to a specimen of scirrhus cancer of the male breast in the museum of the London Hospital.—Dr. Coupland inquired whether any special allusion had been made in Dr. Creighton's report on Mr. Wagstaffe's case to any vacuolation of the mammary gland cells at the growing margin of the cancer, as this was a character insisted on by Dr. Creighton himself as of essential importance in the development of new growths. Dr. Coupland added that at the margins of the syphilitic gumma in the liver he had just described there was notable vacuolation of the hepatic cells, confirmatory of Dr. Creighton's views.—Mr. Wagstaffe stated that here and there vacuolated cells were met with, but they did not appear to be specially related to the development of the cancer in his case; and their presence had not been laid stress on by Dr. Creighton.—Mr. Marsh pointed out that fibrous tumours beneath or in the neighbourhood of the mamma might be mistaken for schirrus, and he referred to a case where a fibrous growth beneath the gland was prior to removal held to be cancerous.—Mr. Wagstaffe explained that he only tabulated cases which had been recorded as "cancer." Doubtless some were not malignant.—The President had seen three cases of true scirrhus in the male breast. One case, in which he had operated about nine years ago, was still living. Another case was followed by recurrence, but the patient was lost sight of. Lastly, the third case was that of a gentleman from the West Indies, on whom removal was practised two years ago, with, as yet, no recurrence. He saw the case operated on by Mr. Hawkins, the patient dying from apoplexy six years after.

Mr. Heath showed specimens of Cystin Calculi removed from a male twenty-eight years of age, who had previously passed a few calculi when he was seized with retention of urine. Passage of a catheter disturbed numerous calculi, which Mr. Heath extracted by median lithotomy. The calculi were 19 in number, all but 3 being imbedded in the prostate. They were of greasy section, not yet green in colour, a change which Mr. Heath pointed out was due to exposure to light, supporting this statement by one or two interesting facts. It was curious that so many of the calculi should have occurred in the prostate, since they are certainly of renal origin. The larger ones from the bladder presented a nucleus and concentric lamination of their outer layers, the latter character being unusual in cystin calculi. Only once after the operation was cystin found in the urine. Mr. Heath showed a specimen of the same calculus removed by Liston by lithotrity, and he read passages from a letter from Sir Henry Thompson concerning the only case that gentleman had had.—Mr. Hicks, who had examined the calculi chemically, microscopically, and by means of the polariscope, stated that they were almost wholly made up of pure cystin, even the larger ones in which the lamination occurred. He had found, further, that cystin crystallises in two forms—viz., (1) in six-sided prisms, as usually described; and (2) in four-sided tables;—the latter from hot solutions.

Mr. Heath then exhibited a specimen of Epithelioma of the Tongue and Lower Jaw, from a male aged fifty-two.

When first seen there was extensive disease in front of the tongue, with infiltration of the sublingual tissues. Two months later Mr. Heath removed the diseased structures by laying open the lip down to the hyoid bone, sawing through the jaw on each side of the symphysis, and removing part of the tongue and subjacent soft tissues with the galvanic écraseur. The patient made a good recovery, and although three inches of the jaw were removed, the two halves came well together. The tongue was chiefly free from disease. There was not much pain in the part, but the patient had suffered from pain in the occipital region, which disappeared after removal of the mass. This could hardly be due to extension of the disease to the base of the skull, as in a case recently reported. He also showed a specimen of Cancer of the Rectum, in which colotomy had been performed two years and nine months before death. At the time of operation there was difficult defecation, and an epitheliomatous mass protruded from rectum. The disease involved the vagina. Besides the local mischief, there was found after death a large mass of secondary growth in the liver, far advanced in degeneration.

Dr. Hilton Fagge showed a specimen of Carcinoma Lipomatosum, obtained from the right kidney of a female aged fifty-seven, who died from bronchitis and emphysema. The left kidney was granular. The right kidney was smooth on the surface, here and there exhibiting whitish nodules, and the whole of the hilus was occupied by what appeared to be fat, only it grew into the substance of the organ, and invaded the renal vein. It did not grow into the pelvis or calyces, which were compressed by it. When examined in the fresh state under the microscope it seemed wholly made up of fat-cells, but after hardening it presented the typical alveolar structure of carcinoma, resembling the variety mentioned by Cornil and Ranvier, who were the only writers who mention its existence. There were no secondary nodules.

Mr. Knowsley Thornton showed a recent specimen of a Gangrenous Ovarian Cyst. The patient, twenty-eight years of age, was four months and a half pregnant when she came under the care of Mr. Spencer Wells for an ovarian cyst. The cyst was tapped, a procedure followed by slight rise of temperature on the few following days. Five days after tapping the patient became suddenly collapsed, with thready pulse and falling temperature. She slightly rallied, but next day, when ovariotomy was decided on, the alarming symptoms were again renewed. Methylene was administered during the operation of removal, and she seemed to improve, but died the same night. The cyst, which had been to the right of the pregnant uterus, was found lying behind this and to the left, the pedicle being twisted and the cyst itself in a state of gangrene. The fluid in the peritoneum, too, had a mawkish odour.

The meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

At the meeting held on Nov. 1st, Dr. Routh, President, in the chair, the time was principally occupied by a revision of the laws of the Society. Some alterations were made, amongst which was a change of the hour of meeting from 8 o'clock to 8.30.

At a late period of the evening Mr. W. Adams exhibited a patient on whom he had operated for Obliteration of Depressed Cicatrices. The patient, Miss S——, aged twenty-six, had presented four cicatrices on the neck, one of large size on each side below and behind the angle of the jaw, and one on each side under the jaw towards the chin, the two latter being of small size, but deeply depressed, with adhesions to the bones. Of the two former the one on the right side was deeply depressed and adherent to the bone, but the corresponding one on the left side was not depressed. All these cicatrices were the result of abscesses caused by necrosis of the jaw-bone proceeding from difficult dentition in cutting the wisdom teeth at the age of twenty. The teeth had been extracted with difficulty, but small portions of bone continued to come away for several years, and all the molar and some other teeth on both sides of the lower jaw had to be removed. The operation performed for the large depressed cicatrix on the right side consisted in subcutaneous division of all the deep adhesions, and then thorough eversion of the cicatrix, turning it as it were inside out, and keeping the cicatricial tissue raised by two needles passed through its base. This tissue, at the time swollen and infiltrated, gradually sank to the level of the surrounding skin after the removal of the needles on the third day. Since the operation, performed more than three years ago, there had been no disposition whatever to a return of the depression, and but a very slight trace remains of the cicatrix. The two smaller cicatrices had been excised, but in one of these depression returned, and at the desire of the patient the subcutaneous operation was performed a month ago, and to all appearances is perfectly successful. Mr. Adams, in conclusion, remarked that the present case was the third in which he had operated by this subcutaneous method, first suggested and performed by himself in March, 1864.—Mr. Spencer Watson congratulated Mr. Adams on the success of the operation in the present instance.—Mr. Coles asked Mr. Adams if he would operate in this way for depressed cicatrices in the groin.—Mr. Royes Bell related a case of a depressed cicatrix with eversion of the eyelid, in which he operated a first time by Mr. Adams's method and failed, but a second time, by transplanting a flap, succeeded.—Mr. Hainsworth did not see any advantage to be derived from operating on cicatrices in the groin.—Mr. Adams, in reply, said he had not operated in this way on the groin, but thought the method might be applied with success.

Mr. Hainsworth exhibited a portion of Meat Preserved by a New Process, which he believed applicable to dissecting-room purposes. The meat had been put in the liquid (of which the ingredients were nitre, common salt, borax, and boracic acid) in March, 1874, and had no smell.—The President and Mr. Lang made a few remarks, and the meeting adjourned.

Reviews and Notices of Books.

Atlas of Skin Diseases. Consisting of a Series of Coloured Illustrations, together with Descriptive Text and Notes upon Treatment. By Tilbury Fox, M.D., F.R.C.P., Physician to the Department for Skin Diseases in University College Hospital. Part I. London: J. and A. Churchill. 1875.

Illustrations of Clinical Surgery, &c. By Jonathan Hutchinson, F.R.C.S., Surgeon to the London Hospital. Fasciculus I. London: J. and A. Churchill. 1875.

Quite recently the first instalments of these two contributions to pictorial medicine, which are likely to prove valuable and interesting to the members of the profession, have been issued from the well-known publishing house of Messrs. J. and A. Churchill. We have used the words "valuable and interesting" advisedly, for although the opinions of teachers are greatly divided as to the merits of diagramatic representations of disease, it must be confessed that the majority of practitioners and students have a great weakness for works of this class. It is true that some teachers strictly forbid the use of anatomical and physiological atlases in their class-rooms, as calculated to tempt the already too willing student from the rugged roads of experimentation and induction into the pleasanter but less certain paths of imagination and deduction. And it must be acknowledged that the conduct of such teachers is in the main worthy of approval, more especially if graphic illustrations are made to take the place of original study and practical observation. No one can become an anatomist merely by studying an anatomical atlas, for although such an atlas may be legitimately employed to impress more deeply upon the mind of the student the knowledge he has previously gained by dissection and the handling of the dead body, it can, of course, never supplant the actual interrogation of Nature. But if anatomy cannot be learned by means of diagrams and illustrations alone, how much less can a real and substantial knowledge of morbid changes be acquired by such means! To attempt to become a practical physician or surgeon, or, indeed, a physician or surgeon of any kind, by means of an atlas, would be as useless and vain as to attempt to become a geographer merely by studying maps. What maps are to the geographer anatomical and pathological delineations are in many respects to the medical student. They serve as records and standards of reference of what has already been accomplished, as well as to suggest, if they do not actually point out, the direction in which we must travel in search of fresh knowledge. With these qualifications and limitations we give the works before us our hearty approval.

The first part of the Atlas of Skin Diseases, by Dr. Fox, is a new and improved edition of the classical work issued by Bateman in 1817, which, in its turn, was an extension and elaboration of the excellent delineations of Dr. Willan, published in 1798. As Dr. Bateman improved upon Willan's work, Dr. Tilbury Fox has improved upon and even perfected Bateman's work. Of the seven figures in the four plates of the first part of this atlas, which comprise the erythemata and urticaria, four are new; and it is announced that, of seventy-two plates, more than half will be original, the remainder being those used from "Willan and Bateman," but in many cases improved so as more faithfully to represent the appearances of disease. Judging from the merits of the drawings in this part, we have little hesitation in saying that the completed work will prove to be one of the best atlases of the more common forms of skin diseases extant. To say that the work is issued under the editorial supervision of Dr. Tilbury Fox, and that the letterpress is from his pen, is to give the best guarantee of excellence and accuracy. These qualities, together with the low price at which the parts are issued, will, we are confident, secure for this beautiful atlas the large patronage which it deserves.

The Clinical Illustrations of Mr. Jonathan Hutchinson make their appearance under less auspicious circumstances. But if they have not the traditional admiration of several generations of medical practitioners in every quarter of the globe, they have at least the confidence and respect that are paid to the originality and the patient industry of their highly-esteemed author. Mr. Hutchinson enjoys, and has enjoyed for many years, the reputation of being one of the most indefatigable note-takers in London. It is to this praiseworthy habit that we are indebted for these valuable illustrations, which it is proposed to issue in quarterly fasciculi, and it is stated that enough is already in the artist's hands to extend over two years at the proposed rate of issue. When completed the illustrations will embrace affections in all the departments of practical surgery and in every part of the body. The first fasciculus contains four plates of the highest order of excellence, not only as representations of diseases, but as examples of artistic skill. In the first plate is given an almost life-like representation of an encephalocele in an infant, at the root of the nose, the cerebral tumour protruding through the frontal and ethmoidal bones. The second plate illustrates a large ivory exostosis of the right orbit in a woman aged fifty. In the third plate are given three illustrations of the most common forms of rodent ulcer. In the letterpress that accompanies this plate Mr. Hutchinson alleges his belief that so-called rodent ulcer is really a form of cancer, its peculiarities, in distinction from cognate forms of cancer, depending upon the tissue in which it commences. "If cancerous action," says Mr. Hutchinson, "begins in the prolabium, epithelial cancer will be the result; if on the eyelids, rodent cancer." Rodent ulcer may, however, in the early stages, be permanently cured, and even in the later stages its progress may be entirely arrested, the loss of tissue being often replaceable by transplantation or other means. The fourth and last plate of this fasciculus illustrates some of the different forms of chancre of the penis, Fig. 1 representing an inflamed indurated sore on the glans penis, Fig. 2 a hard sore with great induration on the prepuce, and Fig. 3 showing numerous small sores at the orifice of the prepuce.

After what we have stated above, it is hardly necessary to repeat that we are greatly pleased with both the works referred to, and strongly recommend them to our readers, especially to those who are removed from the great tutorial centres, and have few opportunities of observing some of the less common forms of disease in the living subject.

Zoology for Students: a Handbook. By C. CARTER BLAKE, D.Sc. With a Preface by RICHARD OWEN, C.B., F.R.S. London: Daldy, Isbister, and Co. 1875.

THIS book professes to be the substance of lectures delivered at a metropolitan hospital, and the author tells us in his preface it is his aim "to impart to others the teaching which I had received from the great master of the science in England, in order that younger comparative anatomists .... might be able to transmit to a future generation, in the days of a retrograde anatomy, somewhat of the traditions of Hunter and Owen." We have quoted the author's own words so far in order to show how admirably he has carried out his task! For not only has he imparted the *traditions* of his master, but he has given in so many places his *ipsissima verba* that there can be no mistake he has acted up to his desire. We propose further on to show how this work has been carried out, but we may first examine it as if it were original, and really what it professes to be—a textbook for students. In the first place, then, the whole construction of the book as a zoological handbook is faulty. There are no tables of classification worth noting, and the main subdivisions of the animal kingdom here employed take us back to the days of Cuvier and Lamarck. Thus, among the Invertebrata, we have the divisions of the Mollusca, Articulata, Radiata, and Acrita, and such a "retrograde" course as associating the Molluscoidea with the Mollusca, and retaining a division by which the Annuloida and Cœlenterata are curiously intermingled. We may overlook such conservatism as this in the higher divisions, but when it comes to grouping the class Crustacea under the head of Arachnida, and separating the Acalephæ (still old-fashioned) from the rest of the Hydrozoa, and positively making no mention of the Rotifera (save incidentally under the head of the Infusoria), we lose all patience, and feel inclined to close the book in disgust. The Polyzoa, too, are dragged back to their old place among the Radiata, as if their affinities with the Ascidians had never been made out. Other anomalies would, doubtless, meet the eye if there were an index to the work; but this positive necessity for a scientific textbook—above all, one on zoology—is conspicuous by its absence. The illustrations are many of them old, a few perhaps new, but none of them of much value as explaining the descriptive text on those points where diagrams are most needed. As for the text, we are bound to say that we have seldom met with a work in which compilation more abounded; it is a very patchwork; a passage here and a passage there taken from other writings held together by an original sentence make up the sum of the work.

The work which has been the most laid under contribution is Prof. Owen's "Palæontology." Nearly the whole of the palæontology in the present handbook has been transcribed *verbatim et literatim* without acknowledgment or even a single inverted comma to denote that any other teacher but the writer is speaking. We will give a few passages to show how thoroughly Dr. Carter Blake has followed in the footsteps of his master; premising that he carries his devotion so far as not to confine himself to descriptions of extinct forms, but even to use the definitions of certain classes of living animals which Prof. Owen has prefixed to his palæontological writings, to stand in the text of the handbook as descriptions of the classes referred to. We may instance on this head the description of Cephalopoda on p. 243 (pp. 95 and 96 in the "Palæontology," 2nd Edition), of the Pteropoda on p. 265 (p. 80, *loc. cit.*), of the Articulata, p. 278 (p. 41, *loc. cit.*):—

From CARTER BLAKE'S "Zoology for Students." 1875.	*From* OWEN'S "Palæontology." 2nd Ed. 1861.
"The general form of the skull and aspect of the nostrils places Dinotherium in an intermediate series between *Manatus* and *Elephas*; but limb bones have been found so associated with teeth as to prove that the Dinotherium was a hoofed quadruped of aquatic habits, apparently transitional between the large Lophiodons and the Proboscidians. The Dinotherium is found in the Miocene deposits of Germany, France, Spain, Switzerland, and India."—p. 40.	"In the general shape of the skull and aspect of the nostrils *Dinotherium* most resembles Manatus: but bones of limbs have been found so associated with teeth as to determine the *Dinotherium* to be a hoofed quadruped, of probably aquatic habits, and transitional, as it would seem, between the large Lophiodons and the huger Proboscidians. The evidences of the genus have been discovered in miocene deposits of Germany, France, Switzerland, Perim Island, and Gulf of Cambay."—p. 385.
"No form of elephant is now known in the old world, but in the Post-Pliocene period; the mammoth of species identical with that of England and Siberia ranged over the whole of the North American continent, co-existing with the true gigantic mastodon, and with a second species of true elephant (*E. texianus* mihi seu *Columbi*, Falc.), the teeth of which showed molar plates wider apart, with broader cement valleys, and more alike in form to the existing Asiatic elephant than was the old mammoth, whose teeth were adapted to browse on the branches of the northern pines, birches, and willows. The mammoth and the tichorhine rhinoceros have passed away. The gigantic bovine animal which was their contemporary (*Bubalus moschatus*), and which was like them covered with a thick, hairy coat, the better to adapt its essentially tropical organisation to the cold climate of Siberia, still exists up to the seventieth degree north latitude, and affords in northern regions almost the only gigantic representative of the Post-Pliocene fauna."—p. 42.	"These huge elephants (*i.e.*, the mammoths), adapted by their clothing to endure a cold climate, subsisted on the branches and foliage of the northern pines, birches, willows, &c.; and during the short summer they probably migrated northward, like their contemporary the musk-buffalo, which still lingers on, to the 70th degree of N. latitude, retreating during the winter to more temperate quarters............ The mammoth seems to have enjoyed a wider geographical range than any other extinct elephant. Its remains have been found in the British Isles, continental Europe, the Mediterranean, Siberia, and throughout a large portion of North America, where it co-existed not only with the gigantic *Mastodon Ohioticus*, but also with a second species of true elephant (*Elephas texianus*, Blake), the teeth of which were more adapted to a succulent vegetable diet. Existing elephants are confined to the old world."—p. 395.

It will be seen that but for a slight re-arrangement of the text the passage last quoted from the work under review is almost word for word the same as that written by Professor Owen fourteen years ago. A few more examples will suffice to show that the same curious similarity obtains in other parts of the two works. We find abundant illustrations of this in the chapter on Reptilia—*e.g.*:—

From CARTER BLAKE'S "Zoology for Students," 1875.	*From* OWEN'S "Palæontology," 2nd Ed., 1861.
"Order I. Pterosauria. (Extinct.)	"Order VI. Pterosauria.
"The pectoral members in this order are always adapted for flight by the elongation of the antibrachium and fifth digit. The vertebræ are procœlian......The cervical vertebræ are very large; those of the pelvis are small. The anterior trunk ribs have bifurcate heads. Most of the bones are, as in birds, pneumatic. The head is large; the jaws are long, and armed with teeth."—p. 141.	"*Char.*: Pectoral members, by the elongation of the antibrachium and fifth digit, adapted for flight. Vertebræ procœlian: those of the neck very large, those of the pelvis small. Most of the bones pneumatic. Head large; jaws long, and armed with teeth."—p. 270.

The rest of the section on Pterosauria (p. 142), is made up of a long transcript from the "Palæontology" (p. 274), which is followed by a description of the Dinosauria, composed also of paragraphs from the older work, including even certain quotations from Buckland's writings, also found in Prof. Owen's book.

We might multiply examples without end to show how completely our author has identified himself with his master's labours. The description of the extinct Crustaceans on pp. 305 to 307 corresponds exactly with that on pp. 47 to 49 of the "Palæontology." Sometimes, however, the transcription has been so carelessly done as to alter the meaning of the passage, as, e.g., when "cilio*branchiate*," on p. 273, is given instead of the "cilio*brachiate*" on p. 54 of the original; and certain diagrams illustrative of the geological distribution of mammals and reptiles are inaccurately copied.

Thus, then, the authorship of this work belongs as much to Prof. Owen as to Dr. Carter Blake, and, at any rate, it would have been but fair that both names should have been given as authors. To be sure, the ostensible author tells us in his preface that "he had asked Prof. Owen to give his *imprimatur* to the work," and the title-page leads us to expect that the preface by the now venerable comparative anatomist would be a new one. But it is otherwise. This "*imprimatur*" consists of some "notes" taken from a "course of lectures delivered in the theatre of the Royal College of Surgeons of England;" it must, therefore, have been penned at least fifteen years ago. In fact, we doubt very much if Prof. Owen could have been aware of the liberties taken with his writings when he gave permission for the addition of these notes. If he was, would it not have been far better and far more likely to promote the success of the work if his name had appeared as joint author, and if in that capacity he had supervised a work that sadly lacks supervision? As it is, the student who thinks to find in this handbook a trustworthy account of the zoology of the present day will be grievously disappointed. Had the author only bestowed more care and labour on its production, he might have made it really what it professes to be. But he has not done so, and the appearance of such a volume can only be regarded as an anachronism: it has come into the world twenty years too late.

SCARLET FEVER of a malignant type has broken out at Coal Aston, and several deaths have occurred. The medical officer of health has recommended the closing of the National School, in order to prevent the disease being spread by children going there from infected houses.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 6, 1875.

What the Chancellor of the Exchequer's annual statement is to the financial aspect of public affairs, the report of the Local Government Board has come to be to the social, sanitary, and, in a large measure, the moral, interests of the community. The topics touched on in the *résumé* of the Board are so many and diverse that it is impossible they should be discussed to any useful purpose except in detail. Speaking generally, the Report just issued is not calculated to awaken any great amount of enthusiasm in favour of the Board and its administration. Excluding the very excellent paper of M. Nettleship, every page testifies to the lukewarm and almost perfunctory discharge of public duty that seems inseparable from a system of government in which more than half the legislative and nearly all the executive energy of an authority, existing and acting by sufferance, is absorbed in the attempt to reconcile, or to strike the mean between, conflicting interests. This is especially apparent in regard to the great and urgent question of water-supply and two or three other matters, to which, on the present occasion, we must confine our attention.

The supposed interests of the Water Companies still present an obstinate barrier to any radical improvement. Why these commercial corporations should be held to possess a recognisable property in the public need is not apparent; but the fact that they do, and that to this property all sorts of "rights" injurious to the well-being of the population accrue, is only too obvious. Instead of enforcing such regulations as the public necessities require, the Local Government Board represents, remonstrates, and requires, without the power to command compliance. Sooner or later this state of things must come to an end; but, meanwhile, the people suffer innumerable ills, and the advantage of the many is ruthlessly subordinated to the benefit of the few. While the central and major authority fulminates impotent counsels, it is scarcely surprising that local and minor bodies play with questions of the first moment, or emulate the inertia of their supreme monitor and example. The Metropolitan Board of Works wastes precious time and burlesques business in the controversy about "gross and net value rating" and "meter-supply"; and particularly brainless vestries determine that baths and washhouses shall not be provided, first, because they will not "pay," and, secondly, because the public are "doctor-ridden on the subject of cleanliness," and "it is only necessary that a man should wash his face and hands," which he can do at home in a bowl replenished at uncertain intervals at a reasonable cost—that is, a cost which will enable the Water Companies to pocket a reasonable dividend—from water originally contaminated with sewage or animal matter in the proportion of 1150 in 100,000, or, speaking broadly, liquid manure, and only partially filtered. Dealing with the facts, and disregarding the irrelevant considerations with which these authorities worry themselves and the public, the question is sufficiently simple. Thirty years ago twenty gallons per head of the population was the daily supply required. The development of steam-power and other changes have raised the requirement, and we now need from thirty-five to forty gallons. This supply must be pure. Can the Companies cope with the growing necessity? Is it safe to trust to them? Both these queries must be answered in the negative. It is idle to discuss the minor points of rating by rental value and supply by measure. Water is a necessity of life. Nearly *two-thirds*, by weight, of the animal organism are built up of water. It is not a luxury we are having doled out to us; it is an integral part of ourselves, as essential to life as light or air. The supply of food may be left to the enterprise of commerce, because the pabulum is derived from a variety of sources; and if one runs short or fails, another may be employed to compensate for the deficiency. No such possibility exists in the case of water. The wells scattered over our great cities are contaminated by the habits or processes of gregarious life, and what we call civilisation. The population cannot for a single day dispense with the water supplied from without. Each year strengthens the proof that a point will hereafter be reached at which new sources, far removed from the centres of crowded life and commerce, must be discovered; and it is abundantly evident that, when this time arrives, it will be necessary for the State, the Commune, or the municipality to take the matter into its own hands. It is puerile to postpone the development of a scheme which will inevitably engross much time in deliberation and more in execution.

The first step must be to place the question on a practical footing. This can only be done by the constitution of some corporate authority competent to assume the responsibility and discharge the obligation of supplying a common need. Whether the supply will ultimately have to be brought from a distance, so as to comprehend the watershed of an extensive open country, or to be raised from the deep strata of the earth's crust—Nature's filter—by a system of artesian wells, the undertaking must reach a magnitude and be of a character too important to be carried out by commercial enterprise. The same principle which has been applied to the conveyance of letters and the maintenance of the telegraphic system must be adopted in regard to water-supply. The only question is one of time. If anything were needed to ripen this question it would be contributed by the perverse and blind obstinacy of the Companies, the pitiable weakness of the Vestries and Board of Works, and the puppet policy and *laisser faire* of the Local Government Board. The time to speak out and press the matter has distinctly come, and we make no apology for insisting strenuously on the gravity and urgent need of dealing boldly and directly with a problem which claims prompt solution. There is really no serious difficulty in the way of carrying out the transfer. A very simple process of appropriation, with perhaps the creation of municipal bonds to replace the shares now held by proprietors, as recommended by Mr. R. H. Patterson in his interesting work on "The Science of Finance," would suffice to satisfy the utmost legitimate needs of the financial obligation. The community would find it a profitable investment to purchase public health and sanitary facilities at the price of such compensation of "vested interests" as the transfer would require. While this resource—and it is the only available and sufficient one—lies before the country, it is in no mood to bear with the overweening folly and short-sightedness of Companies which trifle with the public health and court their own discomfiture by refusing to take the obvious means to remedy a state of things so intolerable as that represented in the Report. With what sort of temper, for example, are the public likely to regard a remark such as the following, which we reproduce from the Report of Professor FRANKLAND on the supply of the year 1874?—"In December the Chelsea Company supplied this foul water in an unfiltered condition and contaminated with fæcal matter." The average supply of this interesting Company was more than three times—3·7 to 1·0—as bad as the Kent, which derives its supply from the deep chalk wells; and the West Middlesex, Southwark, Grand Junction, Lambeth, and East London Companies are only fractionally better. If the obtuseness of the British citizen were not proverbial, it would be impossible to account for his tacit consent to be fed with so foul a fluid, particularly when the single obstacle to improvement could be instantly surmounted by a combined effort of engineering skill and finance. He can scarcely be wider awake than the Local Government Board, which drones the busy hours away quite contentedly, lulled by the consciousness that on the 29th of June, 1874, it issued a circular on "Water-supply," informing the sanitary authorities that they might now, if they pleased, construct and maintain waterworks, and even dig wells and provide water-carts, where no Company with a "vested interest" to be trenched upon, happened to exist. With such proud doings will a great Government department console itself!

Equally unsatisfactory is the delivery of the Local Government Board on the topic which, until its renaming, was nominally its own. Over-weighted with the conviction that "a certainty of obtaining out-door relief in his own home, whenever he may demand it, extinguishes in the mind of the labourer all motive for husbanding his earnings, and induces him to rely exclusively upon the rates, instead of upon his own savings, for any momentary relief which he may require from the sudden cessation of his usual employment," the Board is unable to perceive that, being driven to brand himself as a pauper and become the inmate of a workhouse the moment he falls into bad circumstances, the labourer and his family are ruthlessly deprived of their chief incentive to self-help, and reduced to a state of moral and physical dependence. The "workhouse test" is the sole remedy which the Board can devise for increasing pauperism; and in this it is the mere reflex of that policy of niggardly "relief"—parsimonious in the present and expensive in the issue—which for the moment so strangely finds favour with boards of guardians. We look in vain for evidences of that far-sighted policy of reform which alone can bring about the amelioration of public social evils grievously felt and widely deplored. There is a discouraging lack of boldness and vigour about the proceedings of the Board which makes itself apparent in every paragraph of the Report. Space will not now permit us to deal with the proofs of this feebleness, but we shall return to them. It is vain to hope for local energy while the authority in which the sum of local forces is supposed to be centred is conspicuously colourless and inert. A masterly energy of reform is what the condition of the country needs, and a policy of sanitary reconstruction and improvement should inspire. It is the want of this zeal and intelligence which renders the influence of the Local Government Board so insignificant, and its Report a meagre chronicle of doings remarkable for their modesty rather than their usefulness.

◆

WHAT may be termed the socio-physiological aspect of twins has received, up to the present time, little attention. The occurrence and the characteristics of twin-births—so strange an anomaly among animals which usually produce but one at a birth—have been abundantly investigated in their more directly physiological aspect. But the life-history of twins, their personal characteristics, their relations to external circumstances, have not hitherto received comprehensive study. We are therefore glad to direct our readers' attention to an interesting article on the subject in the current number of *Fraser's Magazine*. Mr. FRANCIS GALTON has extended to this more special point the means of investigation which he has employed on a wider scale to ascertain the influence of heredity and other conditions upon mental culture. His object in the investigation has been to compare, under similar circumstances, the respective influences of nature and of nurture, of inborn tendencies and of external influences. He has endeavoured to ascertain the effect of diverse training upon twins who in early life manifested a striking resemblance, and, on the other hand, the influence of similar educational circumstances upon those who were at first dissimilar. His materials were obtained by sending out circulars to twins, or to those who were the near relations of twins; and the answers to his queries have furnished him with a series of facts, apparently well authenticated, which, if they have led to no new discovery, at least illustrate very fully the conclusions which had before been reached from isolated observations.

The cases of which details were obtained ranged themselves into three classes—one in which twins presented strong resemblance, another in which they were moderately alike, and a third in which they were strikingly dissimilar. Eighty instances of the first class were met with, of which thirty-five presented instructive details. In a few cases the parallelism between the twins was complete, and in many others the physical resemblance was so close that the most intimate associates were puzzled to distinguish one from the other. Of the mistakes made under the circumstances Mr. GALTON's pages contain some very curious instances, and many anecdotes are authenticated in which one twin had been fed, physicked, or whipped in mistake for the other. In one case, indeed, a doubt still remains whether the children were not changed in their bath, and the presumed A is not really B. In another instance an artist was unable to identify, with the originals before him, the likenesses he had partially completed. Facile impersonations are very frequent, one twin replacing the other for a lesson, a punishment, or a dance, without discovery; and no less than nine accounts are given of one twin seeing his or her reflection in a looking-glass and addressing it as his twin. Even in adult life such mistakes have occurred not unfrequently.

A comparison of these cases shows how little visible effect external influence has had in determining divergence in character or physique. As a rule, resemblance at birth has entailed resemblance through life, even where the external conditions have been remarkably diverse. A profound physical change, entailing often permanent and complete alteration of mode of physical life, has alone sufficed, in most instances, to effect an apparent divergence of development, and even then the resemblance beneath the dissimilarity could often be traced in identical characteristics. On the other hand, in no case of initial dissimilarity was any marked resemblance produced by the most perfect correspondence of surrounding circumstances, lessons, changes, &c. In no case did identity of nurture override and assimilate diversity of nature, and in no case did diversity of nurture produce an essential difference between those naturally alike.

Of more immediately medical interest are the facts which Mr. Galton has obtained illustrative of the frequent identical relations of twins to disease. These facts corroborate very strongly the paramount influences of physique and heredity. The close resemblance of physical condition, which amounts in many cases to a practical physical identity, renders twins liable to be affected in an identical manner by common influences to which they were exposed. Contagious diseases, accordingly, nearly always affect twins simultaneously who are together. Diseases which are not contagious, but depend on external circumstances of very uncertain effect, frequently attack twins at the same time. Asthma and ophthalmia are instances of this, of which examples are cited from Trousseau. Still more striking are the examples in which diseases which can scarcely be said to be related to external conditions—diseases which, at any rate, are mainly the result of internal predisposition—occur at nearly the same time in twins. Mental derangement affords a striking illustration of this, of which some remarkable instances have been collected by Mr. Galton. In another case, two twin brothers died at almost the same time of Bright's disease.

Most of the cases in which differences appeared, as development progressed, between twins at first alike, were determined by a physical influence. In some cases this was a condition which led to a total change of external circumstances. In others it was a mere physical illness, which effected no such change of external condition. In four cases it was scarlet fever, in one typhus, and in one a "nervous fever." The profound effect on development which such influences occasionally produce is well known to physicians, but has hardly before been brought out by so delicate a test as the opportunity for comparison afforded in these cases. It is evident that Mr. Galton has obtained many facts of great interest and importance, and we hope he may pursue his investigations still further in the same and allied directions.

◆

A new series of researches has just been published by M. Bloch on the Rapidity of the Sensory or Centripetal Current in Man. The experiments, which were performed in the laboratory of M. Bernard, appear to have been made with considerable care, and the memoir was read before the Société de Biologie. The experiments of Schelske, undertaken previously, gave as a mean a rapidity amounting to 29·60 metres per second for sensory impulses. In repeating these experiments merely for the purpose of confirming their accuracy, M. Bloch considered it requisite to determine the duration of the persistence of tactile sensations; and for this purpose employed a small disc with projections. This was rotated with increasing speed till the sensation of successive shocks was lost. It was found that when the shocks exceeded fifty per second the sensation became uniform. This fact appeared to him in contradiction with the results obtained by Schelske, at least so far as analogy went; for it is known that, in regard to the senses of vision and audition, the persistence of the impression is longer than the time occupied in its transmission to the cerebrum. But there was here a contradiction to this rule; for with a period of transmission amounting, according to Schelske, to about one-thirtieth of a second, the persistence of the impression was only one-fiftieth of a second. It is unnecessary here to give the details of M. Bloch's mode of experimentation; but it consists essentially of a wheel with a thin piece of quill projecting from its border. This is made to revolve, and, as soon as the sensation is felt, the finger is flexed and scratches a line on the surface of a smoked glass within the rim of the wheel. The physiological time embraces several elements—namely (1), sensation, including its reception at the integument and its transmission through the sensory nerves; (2) the transformation of the sensation into voluntary effort; (3) the transmission through the motor nerve; and (4) the execution of a muscular contraction.

M. Bloch soon found that no modification of experiments of this nature gave satisfactory results, because in all instances the elements of the calculation include a factor—namely, the period occupied in the transformation of a sensation into a voluntary effort—which is incapable of precise estimation, and varies with different individuals and under different circumstances, so that an excitation received by the hand or fingers can actually be recorded more quickly than one received on the forearm or face, though the course of the sensory nerve is manifestly shorter. He then modified his method, founding it on the longer or shorter persistence of the sensations; so that, if two shocks are received successively, one by each hand, when the interval between these two shocks is sufficiently short (one forty-fifth of a second on the average), the two sensations are felt as one. The only explanation of this is that the sensation of the first shock persists with an intensity not sensibly altered when the sensation of the second shock arrives. This persistence appears to augment in duration in proportion as the shock is more rapid, though in feeble proportion. If the second shock be received by some part nearer the sensorium than the first—as on the nose,—apparent synchronism can only be obtained by allowing a longer interval to elapse between the two. The difference of the two intervals will, it is obvious, measure the difference in the duration of the transmissions from the more distant and the more approximate point to the sensorium. The impressions made must of course have the same intensity. The general result of all the experiments performed on these principles gave a much larger figure than that obtained by M. Schelske—namely, 156 metres per second. The rapidity of transmission was greater in the spinal cord than in the nerves, being 194 metres per second in the former and 132 metres per second in the latter. One other fact was ascertained in the course of the experiments—viz., that the persistence of a tactile sensation augments as the acuteness of sensibility diminishes.

◆

Much activity has been manifested on the part of the Royal Commission on Vivisection. The meetings of the Commissioners have of late been more frequent, and very considerable progress has been made in the examination of witnesses. The publication of their report will be anticipated with considerable interest on many grounds. So many sensational, exaggerated, and misleading statements have been promulgated in regard to what is actually done in this country, and so much prejudice and ignorance prevail as to the objects and nature of such experiments, that it is time the truth in regard to these things should be stated. That animal experimentation is perfectly justifiable under certain circumstances few would deny, even among those most strongly opposed to it; and, on the other hand, we believe it to be a libel on the medical profession to suppose that those who recognise the vast importance of such a method of elucidating the truth in physiological or pathological inquiries do otherwise than regard some of the alleged practices in this respect as barbarous and unnecessary. We say alleged, because it is next to impossible to discriminate between what is true, false, exaggerated, or misleading in many of the statements that have been put forward. And we need do no more than point to a paper on the "Moral Aspects of Vivisection," by Miss Frances Power Cobbe, reprinted from the *New Quarterly Magazine*, by way of illustration. This lady can have no personal knowledge of the subject, nor is it to be presumed that she possesses the physiological information necessary to enable her to discriminate between the real and the apparent results of pain in any given animal forming the subject of an experiment beyond that which can be gathered from the perusal of a description of it, drawn up in too many cases in either an inaccurate or a misleading way. Will any candid person say that anything so preposterous could have been present in Professor Rutherford's mind as to have led him to defend the vivisection of animals on the ground of "better fixing an impression by the sight of their agonies than could be effected by the verbal description of a lecturer"? Then, again, it is urged that "keenness of observation, or a memory of their own youthful insensibility, ought to teach all professors of physiology that they are indulging a maleficent tendency which already exists in their pupils' disposition when they invite mere lads of the Bob Sawyer type to watch their frightful experiments—the more frightful, so much, alas! the more attractive." To anyone acquainted with the facts, the incorrect and misleading character of such a representation must be at once apparent. Statements of this kind entirely defeat their object, and rightly so. It cannot be urged by anyone that we have treated this subject of vivisection without recognising the full measure of moral responsibility involved in it, or that we have endeavoured to interpose any barrier to its being fully and dispassionately considered by a properly constituted commission. We shall be glad of whatever light can be let into it; and if the Royal Commission, now sitting, can define the limits of our duties and responsibilities to the lower animals, and say how far we are justified, consistently with these, in having recourse to experiments, we shall be quite prepared to give their report every consideration.

Annotations.

"Ne quid nimis."

THE HOSPITAL SUNDAY FUND.

It will be generally admitted that the Report of the Distribution Committee of the Hospital Sunday Fund is, with some exceptions, almost as satisfactory a document this year as it could be under the circumstances, although it will not in any quarter excite enthusiasm. We are ashamed to have to say that the sum to be divided was less this year than last by £2871 8*s.* 6*d.* The hospitals this year have received only £22,945 12*s.* 11*d.*, against £25,307 12*s.* 3*d.* last year; and the dispensaries have received only £2531 9*s.* 2*d.*, against £3040 18*s.* 4*d.* last year. It is more easy to explain this falling off than to justify it. There are two facts to be regarded as explanatory: the first is, that the Hospital Sunday was unfortunately a very wet day; the second, that the disorderly meeting of those who were dissatisfied with the distribution of last year undoubtedly did much harm for the time being.

While a comparison of the grants of this year with those of last shows, in the majority of instances, a diminished grant, it is not so with all. The Metropolitan Free Hospital gets £280 this year, instead of £78. (We write in round numbers.) The Hospitals for Women have been generously treated, getting this year £583 13*s.* 4*d.*, against £398 11*s.* 10*d.* last year. The special hospitals, exclusive of the Chest Hospitals, which also get more, receive £2138 4*s.* 10*d.*, against £1215 4*s.* 5*d.* The Convalescent Hospitals get this year £989 12*s.* 6*d.*, against £758 2*s.* 3*d.* last year.

An important discussion took place at the meeting of the Council on Monday as to the power of the Council to review or modify the awards determined by the Distribution Committee. Both Mr. Kitto and Dr. Kennedy considered that hospitals and dispensaries dissatisfied with their awards have a right of appeal to the Council according to the instructions agreed upon this year for the guidance of the Distribution Committee; and both Mr. Kitto and Dr. Kennedy took a very active part in formulating these instructions. Mr. Brudenell Carter took the same view, and strongly—but not too strongly—expressed it. The instruction in question is to the effect that the Committee of Distribution shall present their report to the Council before the fund is finally distributed. If this is not intended to be a perfectly unnecessary and misleading instruction, it implies that the awards are not irrevocably fixed until sanctioned by the Council; in other words, that the Council has the power to alter them. Of course it is to be taken for granted that this power would not be exercised wantonly. It seems plausible to claim absolute authority and responsibility for the Distribution Committee, as Canon Miller did. But if that view is to be accepted, the Council ought not to be asked to go through the vain form of endorsing a report. In our opinion, the Distribution Committee, though entitled to great praise and many thanks, is a little too thin-skinned. A little more respect is due to the Council. Can anything be more unreasonable than to summon a meeting at a very short notice to receive the report of the Committee of Distribution, without previously circulating the report, and giving members a chance of becoming acquainted with it? This procedure, it is understood, will not be repeated another year. We are satisfied that the Distribution Committee will do well in giving a little more generosity of construction to the instruction which requires their report to be presented to the Council before the fund is finally distributed. It is by ample criticism and by appeal to the Council that full public respect is to be gained for the distribution.

THE PREVENTION OF INFECTION.

THE peculiar difficulties which beset the control of infectious diseases, and the limitations of the sanitary law as it affects them, are well shown in a case brought, in the course of last week, before the Clerkenwell Police-court. Scarlet fever, at the beginning of September, had appeared in the family of a working-man living in Islington; the disease, as would seem from the reports published in the daily journals, being present among other families occupying rooms in the same house. The eldest child of the workman referred to, while ailing from what subsequent symptoms would indicate as unrecognised scarlet fever, was sent away to Tottenham, returning home some days after with "slight dropsy," which was followed by "low fever." At the beginning of October, a medical man having certified that the children who had suffered from scarlet fever had so far recovered "as to be quite safe as regarded the power of communicating the disease," the workman removed with his family to another residence in a different part of Islington. These facts coming to the knowledge of the Vestry's sanitary officers, proceedings were taken against the workman, first for "transmitting, without previous disinfection, certain articles of bedding, clothing, and other things, which had been exposed to infection from scarlet fever," and, next, for having failed to cleanse and disinfect the premises he then occupied, he having been required to do so, under the provisions of the Public Health Law, by the Vestry. Cleansing in this case was interpreted by the Vestry, through its inspector of nuisances, to mean, among other things, removal of paper from the walls of the occupied rooms. The Vestry failed to sustain its case on the first charge, and substantially the same result followed on the second charge. It was not shown to the magistrate's satisfaction that needful disinfection had not been applied to the transmitted goods; while it was not disputed that the fitness of removal of the family had been certified by a qualified medical practitioner. Again, the requirement of the vestry that the term "cleansing" should be made to include removal of wall-papers, proved a stumbling-block to a summary decision on the second charge, the difficulty in the magistrate's mind not being lessened by the fact of the Vestry's interpretation of the law being presented to him as a matter over which he had no discretionary judgment. This charge was, in consequence, adjourned for a fortnight, in order that, if practicable, some arrangement might be come to between the Vestry and the workman. The magistrate is reported to have observed on this part of the case, that "there seemed to be a most arbitrary power vested in the nuisance authority, and he was powerless in the matter."

The result of this case is very greatly to be deplored. There is much to be done before popular feeling will move smoothly with the present provisions of the law for the control of infection, limited, and, from the strictly medical aspect, insufficient though these may be. It is of peculiar importance therefore that, when it is attempted to enforce the provisions of the law in this respect, the cases should be carefully selected, so as to avoid as far as possible any liability to failure. Few things are more mischievous in the application of sanitary law than a magistrate being brought, as it were, into collision with the sanitary authority to the deterioration of the latter's influence. So careful was the Legislature to provide for the difficulties which it saw must interfere with any attempt at stringent application of the law in this respect, and to meet the prejudice against its enforcement which might thus arise, that it gave power to the sanitary authority itself to effect necessary processes of cleansing and disinfection if owners and occupiers were unable, from "poverty or otherwise," to carry them out effectually and if they consented. So far as published reports afford a means of judgment, this case was eminently one in which the Vestry of Islington should itself have undertaken the cost of the measure it was desirous to have carried out, and not have courted failure, as it did, to the prejudice of the law. What likelihood was there of success on the first charge in face of the medical certificate given by the family medical attendant? Here the Vestry has unwisely contrived to enlist the prejudices of the medical profession against them, as well as the public. And the question is not merely that of the individual judgment of a particular medical man, but of a principle of action which very considerably affects the medical man's relations to his patients. Again, when an important provision of the law is presented to the public as an arbitrary enactment of which the interpretation must rest with an inspector of nuisances, and not with a magistrate, before whom a case based upon it is heard, it must be obvious that such a law will not be long tolerated, and that it must interfere with, rather than help, the object it is designed to promote.

It is particularly unfortunate that, at a time when it is sought to strengthen rather than weaken the law respecting the control of infection, this unlucky case should have arisen to prejudice the magistrate's bench, the medical profession, and the public alike, on the subject.

COLOUR AND HEAT.

THE curious, though somewhat costly experiment of the willow-pattern plate should not be allowed to slip out of memory. It has a bearing on the question of public health. Dr. Richardson did not allude to the topic in his graphic outline of "Hygeiopolis," but it could not be wisely excluded from a scheme worked out more fully than was possible with a fancy sketch, however suggestive and interesting. Having provided your plate, and sacrificed it to the cause of science, you put it into the centre of a clear and brisk fire. Of course it flies to pieces, but some of the fragments are probably large enough to be taken out with a pair of tongs when heated to redness, and exposed in a dark room. The pattern glows white on a dark ground, the explanation being—to speak roughly—that the dark colour of the pattern first absorbs, and then gives off, more heat than the white ground. Apply the same principle to the surface of a town or city exposed to the sun. The relative proportions of dark-coloured area, whether foliage, grass, earth, or black-slate roofing, and of light-coloured surfaces, such as stone pavements, macadamised or chalky roads, will determine the heat absorbed from the sun's rays by day, and the radiant heat given off by night. But more than this, there can be no doubt that just as the comparative heat of tropical and cold regions is one cause of winds—the cold air rushing in horizontal currents from the cooler to the warmer districts of the earth's surface,—so, in a smaller, but not unimportant degree, the displacement of the lowermost strata of the atmosphere, and the consequent ventilation of streets and houses, is affected by the colour of large tracts of surface in and arouud our great cities. The preservation of green lands has a sensible effect on the healthiness of adjacent residential property wholly apart from the facilities which these grounds may offer for pleasure and exercise. The larger bearings of these considerations will be obvious, and one small but singular custom, in which we fly in the face of nature, should be modified by them. White hats and clothes are worn in the summer because they do not so readily as dark-coloured articles absorb the heat. This is a rational expedient, but it is not so reasonable to forget, when winter comes round, that dark surfaces radiate heat, or allow it to escape, as rapidly as they absorb it. At a season when the heat of the body is almost entirely generated and supported from *within*, it seems unaccountable that people should so commonly affect dark clothing. The fact that animals in the cold regions are provided with white furs in winter points to the more judicious selection. The rule is simple enough. When it is wished to take in heat easily or to give it off rapidly, the surface should be of a dark hue; when the object is either to keep out the external heat or to preserve that which is generated within, the colour should be white or bright. The practice of putting on the most sombre and depressing garb at a season when everything has a tendency to look gloomy is unnecessary, and considering that it is the reverse of cheery, it might, with advantage to health and spirits, be extensively modified. There should be no difficulty in procuring stuffs for clothing combining sufficient substance and low-conducting material with light and cheerful colours.

HOSPITAL MORTALITY FROM SCARLET FEVER.

THE difficulty, if not impossibility, of successfully repressing epidemics of scarlet fever and other zymotic diseases, more especially in urban populations, without hospital accommodation to secure isolation of the patients, has been very generally recognised. Dr. Buchanan expressed somewhat recently an opinion that a provision of at least one bed for each 1000 of the population would be necessary in order that we should be fully prepared so to deal with these diseases that they might eventually be stamped out. Comparatively but little of this hospital accommodation has yet been provided, but this only renders the facts that may be learned from the experience of those hospitals in operation the more valuable for future guidance. In London the Metropolitan Asylums Board possess a fever and small-pox hospital at Homerton, and two similar hospitals at Stockwell. The total accommodation provided by these four institutions is 576 beds. As small-pox has scarcely existed in the metropolis during the present year, and the prevalence of fever has been very far below the average, a large proportion of this hospital accommodation since the beginning of the present year has been devoted to the treatment of scarlet fever cases. The Registrar-General in his last Weekly Return published some valuable figures giving the results of the treatment of scarlet fever in these hospitals during the first nine months of this year. The number of cases admitted during this period was 792, of which 385 were treated at Homerton and 407 at Stockwell. The number of cases discharged recovered from the two hospitals was 581, and of deaths 109. The proportion of deaths to cases treated was 14·7 per cent. in the two hospitals: 14·4 per cent. at Homerton and 15·1 at Stockwell. Thus in the two hospitals there were 6·8 cases to each death, and the Registrar-General remarks that "if it were safe to assume that the mortality in scarlet fever cases was the same, whether treated at home or in hospital, it might be estimated that there have been 18,469 cases in London since January 1st last, as we know that 2716 deaths have been recorded." An opinion is expressed that the actual number of cases has been considerably in excess of this estimate, inferring that the proportion of deaths to cases in those hospitals, 14·7 per cent., is higher than in cases treated at home. This is a subject which demands most careful investigation at a time when the provision of these hospitals for infectious diseases is being urged upon the sanitary authorities of so many of our large towns. There is much difficulty, however, in obtaining authentic returns of a sufficient number of cases occurring out of hospital to compare with these hospital results; and it is highly necessary to bear in mind that there is a natural tendency to send the most severe cases to hospital, and to leave the milder ones for home treatment.

PREVENTIVE MEDICINE.

IF the medical profession had simply a keen eye to its own interests we should not find so many of its members in the van of sanitary progress. As a matter of pecuniary profit, merely, it would be better for them if no check were imposed by vaccination on the progress of small-pox; and of all persons in the world, medical men have least apparent interest in taking up the Prime Minister's parable and joining in a crusade in favour of pure air and cleanliness. Let anyone think of the loss that would be incurred by the medical profession in the way of fees, if typhoid fever alone were obliterated from our medical nomenclature! Still, with no slight display of indifference to considerations of personal agrandisement, doctors are never tired of discoursing—and to ears that are dull of hearing often—on the beauties of cleanliness and of enforcing its close proximity to that other virtue with which it is proverbially, though not always practically, allied. Little by little the battle is being won, however, and each year finds people becoming more impressed with the conviction that it is easier to prevent than to cure disease, and that the way to set about this prevention lies close at hand—viz., in ensuring that the common things of life be good and wholesome. If we have no recent great discovery like that of vaccination to boast of, and if we have to content ourselves with the record of its triumphs expressed by the fact that during last quarter small-pox caused only 164 deaths in all England and Wales, we may still point, with some satisfaction, to the progress we are making in tracing diseases to their sources and to our success in attacking them. The doctor of the present day does not consider that he has fulfilled his task when he has prescribed for his patient; he has to ask himself whether the ailment can be attributed to any preventable cause, to satisfy himself on several matters of domiciliary and domestic hygiene, and, in the event of its being an infectious disease with which he is dealing, to do his utmost to secure its circumscription within the narrowest limits. If this be so in civil life, the duties of a medical officer of the public service have to be supplemented by a knowledge of medical topography, a consideration of favourable time and season for an undertaking and a careful preparation of the necessary means and appliances for its successful issue. Two leading articles in the same number of *The Times* recently,—the one on the Registrar-General's Quarterly Return, the other on the Congo Expedition—will serve to illustrate these two phases of preventive medicine, and to indicate that its claims on public attention are being more and more fully recognised.

REGISTRARS AS AGENTS FOR QUACK INFANT MEDICINE VENDORS.

The enterprising proprietors of a widely advertised quack medicine, which professes to afford instant relief in "convulsions, flatulency, affections of the bowels, difficult teething, thrush, rickets, measles, whooping-cough, or vaccine inoculation," and rejoices in the name of "Infants' Preservative," have recently adopted a new method to push their nostrum. A circular has been addressed to every registrar of births and deaths in England and Wales, offering to pay him at the rate of twopence for delivering a circular advertisement of this "Infants' Preservative" together with the vaccination notice at the registration of every birth. It is needless to point out how mischievous such a form of advertising would prove, which in the eyes of the ignorant invests this patent specific with an official sanction, if not recommendation. It is with pleasure we hear that a large number of registrars immediately reported the circumstance of the application to the Registrar-General, who has expressed his disapproval of registrars accepting such an agency, and his hope that "no registrar in England and Wales will comply with the invitation" conveyed in the circular. There is reason to fear, however, that all the 2193 registrars will not see the impropriety of acceding to this application without referring it to their official chief; and it may be hoped, therefore, that the profession and the public will report to the Registrar-General any case in which these circulars have, to their knowledge, been distributed in the manner above described. We shall not be surprised if we next hear of a circular from the Anti-Vaccination League being addressed to registrars, offering payment for the distribution of their pernicious literature at the registration of each birth! If the official distribution of an advertisement of a quack medicine were once sanctioned, we hardly see how the anti-vaccinators could be denied the same privilege.

ENTERIC FEVER ON BOARD THE "CORNWALL" SCHOOL-SHIP.

It is satisfactory to record that during the past week no fresh cases of fever have occurred on the *Cornwall* school-ship, that there has been up to the present time only one fatal case, and that all attacked are progressing favourably. Since the commencement of the outbreak 71 boys have been removed from the ship. Of these 34 were sent to the Seamen's Hospital at Greenwich, and are considered by Dr. Ralfe, under whose charge they have been, all cases of typhoid. Six boys were sent to St. Bartholomew's Hospital, 2 of whom are under Dr. Andrew, 2 under Dr. Church, and 1 each under Drs. Black and Southey. Dr. Robert Bridges, senior house-physician, informs us that 4 out of the 6 cases are classed as typhoid, but that the others are doubtful. Dr. Glen Bott, surgeon to the *Cornwall*, has had under his immediate care 31 cases, all of which are diagnosed as enterica. Of these 1 ended fatally, 8 are still under treatment in the shore hospital at Purfleet, and 22 were transferred to the Corporation hospital-ship *Rhin*, below Gravesend, under the care of Dr. Whitcombe, surgeon to the vessel. There were also sent to the *Rhin* 19 suspected cases, but all these latter are, up to the present time, quite well, and Dr. Whitcombe reports that the sick and convalescent are all progressing favourably. Thus, out of a total of 235 boys, 65 have been attacked, and one officer. With respect to the admissions into the Seamen's Hospital, Dr. Ralfe says: "The first case was admitted on the 20th of September, and was undoubtedly typhoid, with characteristic rash, diarrhœa, and pneumonia. No other cases were admitted till after the 1st of October, and on that day came a group of 19 cases, 10 of which had well-marked rash, with diarrhœa; and others had no rash, but high temperatures and diarrhœa; and 4 had only a high temperature, but no rash or diarrhœa. In most of these cases the high temperatures were continued to the end of the third and beginning of the fourth week. All these patients were admitted between the 1st and 7th of October. On the 17th and 18th of October, 6 others were sent in, less decided in character, 1 only being a well-marked case of typhoid, having a copious rash, diarrhœa, and intestinal hæmorrhage. Another had epistaxis, but no rash or diarrhœa. These are still under treatment, but the other 4 were convalescent at the end of the second week. On the 25th of October a batch of 8 were admitted. There was nothing typical about these, only slight elevation of temperature, and in one or two slight diarrhœa; their temperatures are now normal. I consider all these to be typhoid, the boys who were most susceptible to the poison taking the disease earlier and more severely, and exhibiting more marked symptoms; whilst those who were less susceptible only succumbed after repeated exposure to the infection, and then had the disease in a milder form, the latter cases being evidently extremely mild enteric fever, aborting at the end of the second week."

Several of the more important suggestions made by the Port Sanitary Authority, as to water-supply &c., have been adopted; but it is probable that the *Cornwall* will be entirely emptied and cleansed before reoccupation, when the epidemic is fairly at an end. The advisability of removing the ship to a more healthy situation (as regards the main-drainage outfalls) is also under consideration; but we shall probably be enabled next week to give a summary of the entire sanitary measures recommended. She is in a material degree under the control of the Home Office; and the last three reports of their chief inspector, the Rev. Sydney Turner, are to the effect that the ship was in excellent order, and well administered. A letter from the Port Medical Officer that appeared in *The Times* of Tuesday indicates that, in many respects, school-ships require special attention and supervision, and that, at all events in the Thames, a floating hospital in their vicinity is very much needed.

THE MAUNSELL TESTIMONIAL FUND.

We note with much satisfaction that the fund in aid of the widow and children of our late Dublin correspondent, Dr. Maunsell, raised in testimony of his public services, is augmenting rapidly, and that every prospect exists that a very creditable sum will be obtained. This is as it should be, for work such as Dr. Maunsell has done, and to the furtherance of which he devoted himself with such energy and ability, is worthy of all praise; and when, as in this case, the worker is stricken down prematurely, his family is entitled to every consideration and support.

There is, however, something in the Maunsell testimonial which merits more than a passing comment, and it is this—that this is the first occasion where a gentleman solely engaged in Poor-law medical practice, and whose writings to the superficial observer appeared to be devoted almost entirely to the interests of his Poor-law medical brethren, should have had his work recognised by contributions not alone from that branch of the profession to which he belonged, but also from men like Sir W. Jenner, Sir Dominic Corrigan, and from others in no way connected with the service. Nor is this all; distinguished laymen, such as the Lord Chancellor of Ireland, the Chief Secretary, Sir M. Hicks Beach, and several Irish members of Parliament, have also forwarded their contributions. When the late Richard Griffin, who worked so heroically to redress the grievances of Poor-law medical officers, was *hors de combat*, and a testimonial was originated in recognition of his services, hardly one member of the profession outside the ranks of the Poor-law Medical Service contributed. This evidence of respect on the part of the *élite* of the profession and of distinguished laymen for Maunsell's labours, betokens an immense advance in public appreciation of the value to the community of the services of Poor-law medical officers, and the true nature of whose work in his own country Maunsell did so much to exhibit.

A SUPPOSED HYGEIOPOLIS IN WILTSHIRE.

At the last monthly meeting of the Town Commissioners at Bradford-on-Avon, the medical officer of health reported that the annual death-rate within the Bradford Improvement District during the three months ending 30th September last had been as low as 7·5 per 1000! It is much to be regretted that such a report should prove "too good to be true," as so low a death-rate during three months in this small Wiltshire manufacturing town might have been useful as evidence of the possibility of the rate of 8 per 1000 in the imaginary Hygeiopolis. Unfortunately, however, facts and figures are against the accuracy of this low death-rate. The medical officer of health acknowledges that 20 deaths occurred in Bradford during the three months; the population of the Improvement District at the Census in 1871 was 4871, and as it is improbable that it now exceeds 5000, it is easy to calculate that the annual death-rate last quarter was equal to 16 per 1000 instead of 7·5. It is evident that in order that 20 deaths in three months should give a rate of 7·5 per 1000, the population must exceed 10,000, and it is impossible to believe that the population of Bradford-on-Avon has more than doubled itself since 1871. At the meeting, when the report containing the announcement of this low death-rate was presented, considerable discussion took place among the commissioners as to alleged nuisances arising from slaughter-houses in the town. The general conviction seemed to be that these slaughter-houses, although not considered nuisances when they were first used as such, are without doubt improperly situated now, and that nothing would be satisfactory except their removal out of the town. In spite of the blunder now pointed out, Bradford-on-Avon appears to have enjoyed good health lately, but we would urgently recommend its sanitary authority to abate the slaughter-house nuisance that exists in its midst at once, and not to wait for a high death-rate to result therefrom before taking active steps in the matter.

PROPYLAMIN IN ACUTE RHEUMATISM.

This remedy, which was first recommended by a German army surgeon, has been used with remarkable success in the Garrison Hospital at Dresden. According to his report in the *Berlin. Klin. Wochenschrift*, Staff-surgeon Dr. Leo treated twenty-eight soldiers exclusively in the manner first tried by Dr. Loewer, of Altenburg. Of a solution of one gramme of the drug in 120 of peppermint-water, with 10 of sugar, a tablespoonful was given every two hours; altogether from three to five grammes were so taken by each patient, whose limbs were bandaged with cotton-wool and cardboard. All the twenty-eight cases suffered from multiple joint affections; in fourteen cases the disease appeared for the first time, in the other fourteen it was recurrent once or repeatedly. Five cases were complicated with slight, five with severe affection of the heart, one with acute œdema of lungs, and one with diphtheria. All were restored to perfect health and military duty except one, which required a course of the Teplitz waters, though there is a certain prospect of his ultimate fitness for service also. The average duration of the illness in these cases was 17·7 days per head; none was discharged before full recovery was proved by increased weight of body and gymnastic exercises. The effect of propylamin is summed up by the author to have been marked by the following points:—1. The disease becomes very soon subacute, and remains so to the last. 2. The sedative effect on the nervous system is shown by decreased tension in the circulatory apparatus; pulse and respiration become slower, and high fever decreases within thirty-six hours. 3. With at first profuse, then more gentle perspiration, pain decreases very markedly. 4. The colour of the skin acquires a peculiar greyish tint (?) 5. Sleep quickly returns, and is not interrupted by pain. 6. With a cleaner tongue appetite returns fast. 7. The quantity of urine is not much increased; it is mostly clear and transparent, only slightly acid, and with little sediment. 8. All patients took the drug without dislike; it was never applied externally. The discrepancy of results in the use of propylamin Dr. Leo ascribes to the great differences in its preparations. According to the careful analysis of Petit, the amount of alkali in the officinal drug varies from 0·02 to 0·55 in 1 gramme. This may be due to the defective mode of preparing it, or to the variable constitution of the herring-brine from which it is made.

"SEA LEGS."

Nothing is more curious among the phenomena of sea-sickness than the disappearance of the symptoms while their cause persists. It is a remarkable instance of the rapid accommodation of the organs of the body to conditions which at first produce a very profound disturbance of their functions. The mechanism of this accommodation will be understood only when we know with certainty how sea-sickness is produced. It must be remembered that the effect is comparative, not absolute. A passenger making an occasional voyage, who has become accustomed to a moderate degree of movement and can bear it without discomfort, is prostrated by a greater degree or an unusual variety of movement. Even the sailor who is undisturbed by any motion of his ship may be rendered sick by that of a small boat. This acquisition of indifference to the motion of a ship is usually simultaneous with that of the power of balancing the body so as to counteract the lateral inclination of the vessel to one side or the other. A correspondent has called attention to this circumstance and to the relief afforded to commencing discomfort by a similar studied adjustment of the position of the body to the surface of the vessel, so as to counteract its displacement. He points out that animals may sometimes be observed to neutralise the lateral roll of the vessel in the same way. But such adjustment can counteract none of the vertical movement of the ship, and there is strong evidence to show that it is the vertical motion to which sea-sickness is chiefly related. The acquired indifference to the toss is clearly more than the advent of the "sea legs," although the two are often simultaneous.

THE CROYDON FEVER EPIDEMIC.

During the week ending 30th ult. no less than seven more fatal cases of enteric fever were registered in Croydon, raising the number of deaths which have resulted from the disease since the outbreak of the epidemic last spring to 72. The number during the last week of October exceeded by two that in any previous week of the epidemic. The Registrar-General considers that the first fatal case of the epidemic occurred in the week ending 27th February, but during the seven weeks ending 10th April the deaths only averaged one per week. In the next nine weeks, ending 12th June, 28 fatal cases occurred, averaging rather more than 3 per week, after which the fatality declined again to

17 in the next fourteen weeks, ending 18th September. After the middle of September the disease again became more actively fatal, and caused 20 deaths in the six weeks ending 30th October, a higher average than at any previous period of the epidemic. Although this epidemic has now prevailed for more than eight months, and has caused these 72 deaths, independently of a far larger number of attacks, it may be said that no earnest and thoroughly independent attempt has been made to discover its real cause. One-half of those in Croydon who trouble themselves about this remarkable epidemic are as certain that it is due to the contamination of the Croydon water through its intermittent supply, as the other half are determined to accept no other cause than the sewage farm. Under these circumstances we are glad to see a suggestion from a correspondent of the *Croydon Chronicle*, that a general meeting of the inhabitants should be called to consider what means ought to be taken to ascertain the cause of this epidemic. An appeal from an influential public meeting of ratepayers to the Local Government Board for a thoroughly independent investigation of all the circumstances of the epidemic by one of their experienced medical inspectors, would probably be the most judicious step that could be taken. It is of far more than local interest that the cause of the Croydon epidemic should be discovered, as each epidemic which is satisfactorily traced to its true source is not only a valuable contribution to our knowledge of the causation of disease, but it weakens the power of what has been called "vulgar fatalism," which is the greatest obstacle to sanitary progress.

SANITARY PROGRESS IN TOWN AND COUNTRY.

In the Quarterly Return just issued by the Registrar-General especial reference is made to the evidence of sanitary progress afforded by comparison of recent death-rates in town and country, with those which have prevailed in past years. During the three months ending September last, the annual death-rate in the thirteen millions and a half persons living in our large towns was equal to 22·3 per 1000; whereas in the remaining population of rather more than ten millions, living in the smaller towns and villages and in purely rural districts, the death-rate was but 17·2 per 1000. Compared with the average rates in the same populations during the corresponding quarters of the ten preceding years the urban rate showed last quarter a decline of 1·6 per 1000, but the rural rate had only decreased by 0·1 per 1000. A comparison of the mortality from diarrhœa during the recent summer is instructive. In our eighteen largest towns the annual death-rate from diarrhœa during the summer quarters of 1873 and 1874 had averaged 4·5 and 3·8 per 1000, while in the same quarter of this year it further declined to 3·6. In fifty other large towns this diarrhœa-rate has been successively 2·9, 3·0, and 3·2 per 1000. In England and Wales, exclusive of these sixty-eight large towns, the rate from diarrhœa, which was but 1·3 per 1000 in the third quarter of 1873, had increased to 1·4 and 1·6 in the same periods of 1874 and 1875. Thus, the death-rate from diarrhœa, a disease the mortality from which appears to bear most consistent proportion to sanitary condition, and which in the past three years has shown a marked decline in our largest towns, has somewhat increased in the large towns of the second rank as to size, and has increased more markedly in our principally rural population. While noticing the undoubted evidence of improved sanitary condition in our largest towns, the Registrar-General, in remarking upon the absence of similar proof of progress in the rural districts, partly attributes it to local boards of guardians, who were constituted the rural sanitary authorities by the Public Health Act of 1872, not having yet formed an adequate estimate of their responsibilities under that Act; and partly to the fact that "except in certain localities where combined sanitary districts have been formed, the medical officer of health is usually a local practitioner, often without any special qualifications for the appointment, who receives an almost nominal salary." In our largest towns, with few exceptions, efficient medical officers of health have been appointed who, being debarred from private practice, have devoted their whole energies to the furthering of sanitary progress, and with satisfactory results. In our smaller towns and our rural districts the Registrar-General concludes that "the growing evils of overcrowding, the increasing difficulties of sewage-disposal, and the continued pollution of streams, in many cases used as sources of water-supply, have not even been kept in check." The aspect of sanitary matters in rural districts implies a partial failure of the provisions of the Public Health Act of 1872.

CHLORALISATION.

The popular appreciation of chloral, with its effects for a time so delightful, and ultimately so delusive, will not be lessened by an account copied by a contemporary from *Galignani* of the virtues of this hypnotic. According to Dr. Papillaud, whose paper read before the Academy of Medicine is the basis for the account, chloral is a remedy of almost universal use, and almost unlimited power. Two cases of lock-jaw under his care, and six under that of Dr. Verneuil, have yielded to its influence. In small-pox it has permitted, if not caused, recovery. In pleuro-pneumonia it is equally useful. But its greatest, most precious, and, it must be admitted, most permanent effect is to be found in its power of soothing the last sufferings. "A dying person may thus be spared the physical and moral sufferings of his approaching decease. A consumptive girl, by the administration of chloral, died without pain, instead of wrestling uselessly with asphyxia." Unquestionably sedatives have a place in the treatment of disease of the highest importance, but their use needs careful regulation, and the agony of death can rarely be assuaged except by accelerating its course and hastening its end. Our feelings and belief forbid us to obscure consciousness during the last moments of life, and still more do they add fresh force to the continued validity of the sixth commandment, without a violation of which the euthanasia can hardly be actively secured.

PERVERSITY IN PAVING.

There is no really supreme or controlling authority in the metropolis, and it is vain to expect uniformity of administration. Each vestry does what seems right in its own eyes, or in the eyes of the multitude of its councillors, and the public suffer the consequences. Streets are pulled up or blocked at will by divers bodies, so that it is seldom safe to calculate upon reaching any given spot by a particular route at a fixed time. The chances are always in favour of some authority having blocked the thoroughfare, although it was blocked a week previously "by (some other) authority." The diversity of methods of paving, pitching, and lighting, consequent on the multiplicity of petty governments, is even more embarrassing. A few yards of a roadway will be paved with stone, a length further on there will be asphalte, and then a distance will be laid with wood. Some thoroughfares in the metropolis are conspicuous for this treatment. The Strand suffers seriously, much to the inconvenience of its inhabitants. The residents and those who pass much time in St. James's-street are especially to be pitied. They live under two vestries, which, as a matter of course, cannot agree, even to act on their respective convictions, or guard the interests of their own ratepayers. Wood pavement seems on the whole the best, and probably it need not be so laid as to set the teeth of everyone who drives over it on edge by the vibration communicated to carriage wheels. But it is useless to hope that wood or any other kind of pavement will be generally adopted—first, because, as we have said, there is no controlling authority to reduce the chaos of vestries to order; and, secondly, because these bodies seem painfully bent on proving their entire inefficiency and unworthiness to be entrusted with local affairs, possibly with a view to self-extinguishment. In the interests of humanity to horses, cleanliness, and health, a durable, smooth, and noiseless street pavement is a necessity, and one which ought to be uniformly satisfied.

FLOODS AND FEVER.

MR. R. B. GRANTHAM has called attention to the powers possessed by local authorities to drain land and store water. The Land Drainage Act of 1861 and the Public Health Act of last session appear to provide all needful facilities for self-protection. If any new motive is wanting to compel landowners to take action, it may be found in the fact that after floods like those by which large tracts of country have just been inundated there is a serious peril of virulent fever. The water acts on decayed or decaying organic matter, vegetable and animal, and when it subsides, and the decomposing surface is again exposed to the air, it gives off vapours laden with the germs of disease, and fostering the rapid growth of other germs in the atmosphere which they impregnate. These exhalations, which are, in point of fact, miasmata akin to those which prove so fatal at the close of the rainy season in tropical climates, are not, unfortunately, confined to the districts in which they take their rise. They are liable to be blown by the wind, or borne by the insensible currents on the earth's surface, into neighbourhoods not immediately interested in the financial question whether it is worth while to drain. Just as fever in the hovel may breed fever in the palace, so undrained land in a suburban district may give rise to a malady which will invade and decimate a town. It is desirable that this should be remembered, and even considered, in local councils. Apart from the exceeding folly of wasting all the water which falls in a district, there is the possibility of finding the flood followed by an epidemic of fever, and in this contingency the adjacent towns and "populous places" may participate, although they resolutely decline to share the cost of sanitary precautions and prevention.

TAKING LYMPH FOR VACCINATION.

WE are not sure whether to feel grateful or sorry for a decision recently obtained from a magistrate of the Birkenhead Police-court, whereby the mother of a child vaccinated by the local officer was mulcted in the sum of "five shillings and costs" for refusing to allow "a small quantity of lymph" to be taken from the vesicle on the arm of her infant. It is always unfortunate when the law must be put into operation to coerce a well-meaning but prejudiced person to perform an act to which his own common-sense should prompt him. There is intolerable ignorance prevalent, and we regret to say fostered, about vaccination. The industrious wrong-doing of the opponents of this merciful provision against a hideous social scourge is a scandal to the intelligence of some score of silly fanatics, and the multitude of their dupes. But this prejudice against taking lymph from a vesicle ought long ago to have been extinguished. We cannot but deplore that there has been need to appeal to the law. We fear some reproach attaches to vaccinators. Instead of explaining to the mothers of healthy infants that it is because their children are so clean and healthy they are selected as sources of supply, and that taking the lymph will, as a matter of fact, reduce the irritation attendant on the last stage of the process; and then taking only a moderate quantity of the fluid, medical men too often pounce on the arm, pierce the vesicle so clumsily as to draw *blood*, and by the formidable array of points or tubes charged from the arm strike terror into the mother, and really irritate the child. We are speaking with candour of the results of observation, on a topic which needs to be touched. Vaccinators will consult the best interests of their profession if they deal considerately with the prejudices of well-meaning parents, and avoid creating an impression, wholly groundless, but which it is difficult to remove. Properly performed, the operation of charging a few tubes or points from a vaccine vesicle is a relief to the child, and reduces the amount of inflammation; clumsily carried out the same process is an evil. The thing being necessary, it should be done with care.

THE VETERINARY DEPARTMENT OF THE PRIVY COUNCIL.

DR. ALEXANDER WILLIAMS, as chief officer of this department, has recently submitted to the Lord President his annual report on the working of the Contagious Diseases (Animals) Act during the past year. Three Orders in Council only have been issued, relating to importations from Schleswig Holstein, to foot-and-mouth disease, and to certain hitherto disputed points as to the reading of the Act, including the order relating to glanders. Pleuro-pneumonia has prevailed in England and Scotland, but no case has occurred during the year in Wales. A total of 6898 cattle were slaughtered by order of local authorities, the awarded compensations amounting to upwards of £44,000. No returns of cases of foot-and-mouth disease appear. The summary of details as to foreign countries is very fragmentary, but it appears that during the year under consideration pleuro-pneumonia has existed in Germany and the Netherlands, cattle plague in Greece, Italy, Abyssinia, and Turkey, and foot-and-mouth disease in most of these countries to a greater or less extent.

The importation of foreign animals into Great Britain showed a slight decrease as compared with the previous year. A travelling inspector has been added to the department, whose duties chiefly relate to the transport of cattle, both as regards disinfection and the prevention of cruelty and suffering in the foreign as well as the coasting and inland trades. It is probable that this officer will have plenty of work to do. There are now 1706 inspectors holding office under the Act, 371 of whom are veterinary surgeons and 1021 officers of police.

CHEMISTRY IN SWANSEA.

UNLESS he is belied by the local newspaper, Mr. William Morgan, "analytical chemist and public analyst for the borough of Swansea," gave at the Glamorganshire Quarter Sessions the other day some singular evidence in regard to train oil. He began by producing "certain samples of oil which he said were all a mixture of rape-seed oil and a little train oil, only differing in degree as to proportion. There was a little gallipoli oil in one of the samples." Asked by the Chairman the simple question, "What is train oil?" he replied by the equally simple answer, "I don't know." It was a vegetable oil, but he did not know its constituent parts, and could not say how much of it there was in the samples he had analysed. Here some dim misgiving crossed the worthy analyst's mind, and he added, "(taking a book from his pocket and looking into it), I wish to correct myself; I find here that train oil is taken from a whale." On this the Chairman not unnaturally inquired, "Then it is not a vegetable oil?" and received the now triumphant reply, "No, a mineral." In cross-examination Mr. Morgan explained "that he knew all along that train oil was a mineral oil, but he got confused." We, after reading the report, which we must assume is correct, are compelled to ask whether public analysts of Mr. Morgan's stamp are common in Great Britain. Is it possible for a man to be convicted of crime on the evidence of an "expert" so astoundingly ignorant or so deplorably puzzle-headed? The question is one of the gravest importance to the community, for there is but too much reason to fear that many of those to whom the office of public analyst has been entrusted are quite unfit for it.

AIR-PRESSURE IN THE TREATMENT OF DISPLACEMENTS OF THE UTERUS.

DR. CAMPBELL, of Georgia, advocates the use of air-pressure in the reposition and treatment of displacements of the uterus. He places the patient not in the "knee-elbow," but in the "knee-and-breast" posture. In this position the breast rests on the couch, the knees are placed perpendicular to the same, and the spine allowed to become convex downwards. This permits complete relaxation of the abdominal muscles. While the patient occupies this position he admits air into the vagina, and by this means replaces the uterus. He further recommends "nightly self-replacement," and for this purpose advises the use of the "pneumatic self-repositor." This is a slightly curved tube of glass open at both ends; one end of the instrument is to be introduced into the vagina by the patient in the "genu-pectoral" position, and, according to Dr. Campbell, "self-replacement is completely and instantly accomplished." We have often tried this method, and have found that in some cases it answers admirably, while in others it fails as completely in effecting reposition of the organ. The cases in which it fails are not only those in which adhesions exist, but almost all cases of acute retroflexion with enlargement of the body of the uterus—cases in which reposition can be effected generally by the hands. The cases to which the method recommended by Dr. Campbell applies are, so far as our experience goes, those only where the displacement is slight, and which can easily be reduced by the hand.

DR. HARDWICKE.

THE following report of an inquest is taken verbatim from *The Times*:—

"Yesterday Dr. Hardwicke held an inquest at University College Hospital on Thomas Hoare, aged nine, who, it appeared, died at the University Hospital through a fall. The house-surgeon did not appear. Mr. Murrey, the coroner's officer, in answer to questions, said he had summoned him, and could not account for his absence, unless, as he had heard upon the point, there was some dissatisfaction among the hospital staff that there was no fee. The coroner said the medical officers of hospitals were bound, under the Medical Witnesses Act, to give evidence in all cases in hospitals under their charge without a fee. It might be that they could not come to a conclusion in a case without medical evidence; and conduct of this sort on the part of a medical officer of a public institution had a tendency to bring that institution into bad repute. If, in this instance, the medical officer or house-surgeon had stayed away because he wanted to be paid, it was a most contemptible excuse. Indeed, it in fact amounted to a contempt of court; and, if he were assured that in this instance the medical officer had received the proper twenty-four hours' notice, he would be inclined to put the Act in force, and would do so on repetition. At the request of the jury, an intimation was to be made through the coroner that the jury considered the conduct of this medical officer insulting both to the coroner and the jury, and the summoning officer was requested on all future occasions to summon the medical officer personally, with a clear twenty-four hours' notice, when the coroner threatened, in the event of non-attendance on the part of such medical officer, to enforce the penalties. The jury ultimately agreed, without medical evidence, to return a verdict, 'That the deceased died from the effects of injury to the head caused by falling from a van.'"

The truth of the matter we have ascertained to be simply that the house-surgeon in question, having received no intimation whatever, either written or verbal, that an inquest was about to be held, and being consequently unaware that his services were likely to be required, had left the hospital for the afternoon for purposes of private business. The only person who appears to us to be to blame in the affair is the coroner's beadle, who had failed to serve the house-surgeon with a legal notice. The statement of the coroner's officer as to the dissatisfaction felt among the hospital staff in the matter of fees is, we hear, absolutely untrue. The patient had died in the hospital, and the resident officers, who are all accustomed to appear in the coroner's court, are well aware that no fees are ever paid under such circumstances, that such is the law of the land, and that therefore it would be useless to expect them. On going to press, we have received a letter from the gentleman implicated, which we publish in another column. It will be found to completely refute the allegation made at the inquest.

THE PROGRESS OF VACCINATION IN INDIA.

WERE it not hopeless to expect to produce any effect on the Anti-vaccination League by an appeal to their reason, we might adduce some of the facts which are annually reported from India in proof of the remarkable benefits which vaccination has conferred upon the native races of that country. It must be remembered that epidemics of small-pox are common enough in India, when deaths from that disease may be counted by thousands, that popular prejudice against vaccination has had to be gradually overcome, and that it still continues in some parts of India as strong as ever. The Sanitary Commissioner for the Punjab, in his latest report, shows on the one hand that there has been a steady decrease in the mortality from small-pox in certain districts in proportion to the subsidence of the prejudice against vaccination, and, on the other, that in those districts where small-pox mortality has increased the prejudice against vaccination continues as strong as ever, and the people resort to all sorts of subterfuges to defeat the efforts of vaccinators. In the small town of Jagadhri, in the Umballa District, there were no less than 433 cases, with 93 deaths, and the progress of the epidemic was rapidly extending, but, owing to very great efforts on the part of the medical authorities to spread vaccination, the western half of the town had scarcely a case.

A PLAGUE SPOT.

MR. J. J. SKEGG has, in a report presented to the vestry of St. Martin's-in-the-Fields, drawn special attention to the fearfully insanitary condition of Bedfordbury, and has pointed out that it is an area which may well be dealt with under the Artisans' Dwellings Bill of the past session. It seems that the population of this notorious group of houses average nearly seven hundred to the acre, and that the houses themselves are wholly unfit for human habitation. Mr. Skegg's report gives a terrible picture of a condition of things which we fear is far from uncommon in many parts of London, and to remove which it is to be hoped that the local authorities will exert all the powers vested in them. When we read of thirty-six inhabitants packed in a house of nine rooms, with one filthy closet and one cistern, with a staircase so rickety as positively to be dangerous, and when we are told that the case is not exceptional, we feel that grave responsibility will rest with those who allow such a condition of things to remain. Much money has been and is being spent to improve "the finest site in Europe," but we cannot feel quite sure that it is justifiable to spend large sums upon decorating our public places while they are allowed to act as screens to an amount of squalor and misery which makes one shudder to contemplate. What would be the opinion of an intelligent foreigner on visiting this country, which has spent millions on the abolition of slavery and on various foreign missions, should he discover that within a stone's-throw of the National Gallery, and in the absolute centre of the metropolis, there exists a potential plague-spot, which seems to mock at our professed Christianity, and to declare that our social progress is a sham?

THE WORCESTER INFIRMARY.

THE Executive Committee have passed the following resolution, which has been adopted unanimously at a meeting of the Governors:—

"That the following addition be made to Rule 59:—'In case of the unavoidable absence of the hon. medical officer and his substitute, the house-surgeon shall attend to the out-patients of such absent officers, and shall record the fact of his having done so in a book to be laid before the Executive Committee; and the hon. medical officer, when called upon to do so, shall furnish such explanations, not in violation of professional confidence, as the Executive Committee may require.'"

We are not averse to the principle that if honorary medical officers fail often to keep their engagements they should be responsible to the Executive Committee. But perhaps a little more gracious way of stating the principle might have been devised than the rider of Earl Beauchamp, which is suggestive of rather more inquisitiveness than it is pleasant to think of. Let us hope that the good taste of the Executive Committee will prevent them from spoiling the just concession which they have made.

THE CONGO EXPEDITION.

WE are very glad to notice the just, and even liberal, recognition, in Commodore Hewett's despatches, of the valuable assistance afforded by the medical officers in the above expedition. When the Ashantee war commenced it was said, and said with great truth, that it was a battle with climate and disease for our enemies; and the results of previous experience on the African coast were naturally quoted to give point to the gloomy predictions then so common. It is only by the exercise of great judgment in selecting a proper season, and by extreme care and thoughtful consideration in making the preparations for such an undertaking, that it can be carried out at all. The naval doctors, in this Congo affair, rendered essential services, and they are to be congratulated on the prominent position their names occupy in the Commodore's despatches to the Admiralty.

ST. ANDREWS GRADUATES' ASSOCIATION.

UNDER the revised name of the "St. Andrews Graduates' Association," the St. Andrews Medical Graduates' Association has been reconstituted. The Council of the Association is actively engaged in promoting the re-election of Dr. Richardson, F.R.S., as assessor of General Council in the University Court of St. Andrews—an office which has fallen vacant by the resignation of Patrick Anderson, Esq. Dr. Paul is honorary treasurer, and Dr. Sedgwick resumes the office of honorary secretary.

THE MANDAMUS AGAINST THE KEIGHLEY GUARDIANS.

ON Wednesday last, in the Queen's Bench Division of the High Court of Justice, an application was made in this case, which was admitted by counsel to be of a "most unusual and novel" character. The application was for a rule calling upon the Local Government Board to show cause why the mandamus should not be quashed, on the ground that the guardians were not in a position to appear when the rule was argued, as they were taken by surprise! Counsel said the guardians were anxious to "explain their reasons why the writ ought not to have been issued," which they were unable at the time to do; he also admitted that they could not make a return to the mandamus, although he told the Lord Chief Justice that the law and the facts were all on their side. The Lord Chief Justice rejoined: "Then you can make the return. We cannot assist you." The application was refused.

MORTUARIES.

A LEADING article on this important subject which appeared in *The Times* of the 1st inst. will, as we hope, induce the Metropolitan Board of Works, through their chairman, to deal with the question comprehensively. If, indeed, as our contemporary indicates, the laws that now prevent the conveyance of a dead body over certain boundary lines were repealed, and the wants of the metropolis regarded as a whole, the number of mortuaries need not be very large. As the operation of the Artisans' Dwellings Act tends to lessen overcrowding, so will it also tend to diminish the urgent necessity for mortuaries. But until these buildings are established and used systematically, no considerable advance can be made in preventing the spread of contagious and infectious diseases. A corpse ambulance should be attached to each mortuary, so that the dead might be removed decently, and without any unnecessary delay.

H.R.H. THE PRINCE OF WALES.

WE are glad to be in a position to state that the health of the Prince of Wales and his suite had been most satisfactory up to the time of their arrival at Port Said. The temperature was of course felt to be increasing by those on board the *Serapis*, but everything had gone well; the weather had been fine and the water smooth, and a subsequent telegram from Aden indicated that the Prince's health, as well as that of the whole party, had not been in any way affected by the change of climate, food, and mode of life. His Royal Highness was in excellent spirits, and much enjoying his trip.

HARVEIAN SOCIETY.

A LARGE attendance of members and visitors assembled at the first meeting of the Harveian Society on Thursday, Oct. 21st, when Mr. Carr Jackson read his paper "On the Early Recognition and Treatment of Lateral Curvature of the Spine." Mr. Jackson is known to have devoted special attention to this subject, and his very practical and suggestive remarks gave rise to an interesting discussion. Numerous applications for membership were received, and it is evident that this useful Society will derive fresh impulse from the establishment of the Harveian Lectureship.

HEALTH OF POST-OFFICE SERVANTS.

THE Twenty-first Report of the Postmaster-General on the Post Office is issued this week. We find that the health of the *employés* in London was last year exceptionally good. There was a diminution in the number of ordinary cases of illness to which the working staff are always liable, such as bronchitis, catarrh, and rheumatism; and Dr. Waller Lewis, the chief medical officer of the department, adds that if a more perfect system of ventilation without draughts could be devised for the various offices, these diseases would be still further reduced. The mortality from all causes amounted to between 6 and 7 per 1000. Attention is again called in the Report to the reprehensible practice of giving drink to letter-carriers—a practice which, it appears, is carried on to an extreme extent at Liverpool.

EPSOM COLLEGE.

WE have received several letters desiring us to direct our attention towards the sanitary condition of the Royal Medical Benevolent College at Epsom; and we have inserted letters both from those who blame and those who defend the management. We intended to have reported on the College this week, and had arranged for the visit of our Commissioner, but the head master wrote to say that, as the governing body were responsible for the management of the school, he would rather that we made our application to them. This we have done, and we have now received the official sanction to make our inspection.

AT the recent Berks Quarter Sessions the medical officer to the gaol, Mr. O. C. Maurice, reported the following extraordinary case to the Court. One day he was told that a prisoner in the reception-cell wished to see him immediately. On proceeding to the cell he found the man lying on his face quite dead. An inquest was held, and a verdict of "Death from natural causes" was returned, in spite of the protest of Mr. Maurice, who rightly urged that it was impossible to ascertain the cause of death without making an autopsy. The prisoner, who was a hale, hearty-looking man, in the full vigour of life, was admitted on a Monday night, and in the early part of the next day was lying dead; and yet no post-mortem examination was allowed to be made. The inquest, which resulted in the finding above stated, was worse than useless. The man might have died from violence, poison, or have committed suicide. We are glad to find that Mr. Maurice, with the sanction of the visiting justices, has forwarded a statement of the case to the Secretary of State. A somewhat forcible expression of opinion may reasonably be expected from this august functionary.

THERE are few medical officers of health in the kingdom who in their periodical reports have not to comment on the increase developed in the rate of infantile mortality. The medical officer of health for Nottingham, in a report on the health of the town during the third quarter of the year, deals at some length with the subject. In all centres of industry where it is the custom to employ women in manufactories maternal neglect of course ranks high as one of the causes of the waste of infant life. Apart from this, in Nottingham the districts where the mortality below one year of age is highest are those where the houses are of the worst construction, dirtiest, and most closely packed together—in effect, to bad sanitary conditions is due a large amount of the extra mortality prevailing.

THE memorial stone of a new hospital was laid at Stockton on the 30th ult., by Mr. Marshall Fowler, J.P. The hospital and its appurtenances will occupy two and a half acres of ground. The buildings now being erected consist of two blocks, the administrative department and the Marshall Fowler wing, which will afford accommodation for thirty in-patients. Should the means be forthcoming, it is intended at some future time to add other wings, when it is estimated that the number of beds may be raised to 102.

AT a meeting of the Strand Board of Works held on Wednesday last, Dr. Joseph Rogers gave notice of the following resolution:—"That this Board, having learned with astonishment and regret that the Metropolitan Board of Works has declined to undertake the establishment of public mortuaries in the metropolis, notwithstanding the representations contained in the memorial of this Board, and the confirmation of the facts by the chairman of the Works Committee of the Metropolitan Board, to which body the question had been referred in bringing up their report, feels that the question cannot be allowed to remain any longer in abeyance, and therefore directs the clerk to write to the President of the Local Government Board requesting him to grant an interview to a deputation from this Board, who desire to make such representation as may induce the Government to take action in the ensuing session of Parliament." The resolution will be considered at the next meeting of the Board, and, should it be adopted, Sir Charles Russell, Bart., and Mr. W. H. Smith, the representatives of the borough in Parliament, will be asked to introduce the deputation.

MR. WM. PENNY BROOKES, F.R.C.S. Eng., has been publicly presented with a testimonial and an address referring to his long residence at Much-Wenlock, and his public spirit and industry in everything relating to the welfare of the town, but especially with reference to the establishment of the Wenlock Olympian Society. The testimonial consisted of an elegant tea-service, epergne, and salver, the latter bearing the following inscription:—"Presented to Wm. Penny Brookes, of Much-Wenlock, F.R.C.S., by neighbours and others, in token of their sincere esteem, and of their appreciation of his life-long devotion to objects of public welfare and the improvement of his native town."

IT may not be generally known that Sir Trevor Lawrence, who is now seeking the suffrages of the electors for Mid-Surrey, is a member of the profession. We hope our medical brethren in the constituency will show that they are not unmindful of the claims which the present candidate has upon their support. An augmentation of the scanty number of doctors in Parliament is highly desirable, in the interest alike of the public and of the profession. Who so fit to take part in debates on the large questions of sanitary reform, which can be shirked no longer by the Legislature, as men who have had a practical acquaintance with the destruction entailed by a disregard of the laws of health?

WE would call the attention of our readers to the fact that the opening meeting of the Epidemiological Society will be held on Wednesday next, on which occasion the new President of the Society, Mr. J. Netten Radcliffe, will deliver an inaugural address. We believe the subject of Mr. Radcliffe's discourse will be the progress of epidemiology in England during the past quarter of a century. From Mr. Radcliffe's profound acquaintance with this important branch of medicine, a most instructive and lucid exposition may be anticipated.

WE are enabled this week to contradict a somewhat prevalent rumour to the effect that an outbreak of typhus fever had appeared in certain parts of Richmond. We are assured that the town is singularly free from fever of any kind. The cases of typhoid which occurred some time back are said to have been mainly imported from other localities.

THE winter session was commenced at Edinburgh University on Monday last, when the opening address was delivered by Sir Alexander Grant, the principal. In the Medical School, Mr. Chiene gave an introductory address.

Galignani announces that Madame Brés, M.D., is about to commence medical practice in Paris. It will be remembered that a few months ago it was reported that this lady had been offered a handsome salary if she would take charge of the Sultan's seraglio at Constantinople, but that the terms of the engagement were too irksome to permit her to accept the offer. We shall be curious to learn the result of the experiment now undertaken by the lady.

The East London Medical Defence Association last week recovered another penalty of £20 and costs under the Apothecaries' Act, from a person who was practising without legal qualification at the east-end of London. As in the two recent cases in which similar penalties were recovered, so in the present instance, registered medical men are said to have endeavoured to protect the defendant.

An Exhibition of £50 per annum, tenable for three years, granted by the Clothworkers' Company, will be awarded at the University of Cambridge on the 13th of January next. The examination will embrace certain selected branches of physical science. Further information may be obtained on application to the Rev. R. B. Somerset, censor.

The Lords of the Admiralty have recently issued an order to the effect that no boys are to be employed in cleaning or working in the double-bottoms of ironclad ships. The unhealthy character of the work has been repeatedly alluded to in various reports by the medical officers attached to the Royal dockyards.

On Monday, November 15th, at 4 p.m., Sir Henry Thompson will commence a short course of Lectures on the Surgical Diseases of the Urinary Organs, at University College Hospital. The lectures are open to all students and practitioners of medicine.

We are requested to state that the Medical Society of London will henceforth meet on Mondays, at 8.30 instead of 8 o'clock.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The earnestness and thoroughness with which Sir James Paget conducts everything he takes in hand are beginning to make themselves manifest in the transactions of the Council of the College of Surgeons. The short time that has elapsed since the inauguration of his presidency has seen the consummation of some useful reforms, and the dawning of several others. Many of the old traditions of the College have been entirely broken through, and some things previously undreamt of have been realised. The Professorship of Surgery has been given to a gentleman who is professedly an ophthalmic surgeon, with the distinct understanding that he shall deliver a course of lectures on ophthalmic medicine and surgery. Mr. Erichsen was recently elected to the Court of Examiners on the assumed condition that the examiners in anatomy and physiology should be distinct from those in surgery; and the nature of the business conducted at an extraordinary meeting of the Council last Monday clearly showed that Sir James Paget is determined that his colleagues shall not at present rest on their oars.

On Monday last the report of the committee appointed in March last to consider and report to the Council on the best means of giving effect to the new bye-laws ordained by the Council on the 10th of December last, relating to the examiners and examinations in anatomy and physiology, was read and accepted. The report refers to four important subjects—the mode of appointment of the Board of Examiners in Anatomy and Physiology; the mode of payment of the members of the Board of Examiners in Anatomy and Physiology, and of the members of the Court of Examiners for the membership; similar regulations respecting the examiners for the fellowship; and, lastly, the consideration of the degrees, diplomas, licences, and certificates to be recognised as exempting candidates from examinations in anatomy and physiology for the membership and the fellowship.

The recommendations of the committee were as follows:—The Board of Examiners in Anatomy and Physiology should consist of nine members, to be appointed by the Council annually from the Fellows of the College, and to hold office not longer than five years at a time, at least one member of the Board, who shall act as chairman of the Board, being a member of the Court of Examiners. A committee of three members of Council, Messrs. Hilton, Hancock, and Marshall, together with the President and two Vice-presidents, were appointed as "the Committee on Examinations in Anatomy and Physiology," it having been decided that at least two of the members of the committee shall have been members of the Court of Examiners. The duties of this committee, the members of which are ineligible for the office of examiners in anatomy and physiology, are to consider the applications from candidates for the office of examiner in anatomy and physiology, and to report thereon to the Council, and recommend the candidates they deem fittest for election, and to be visitors of the examinations in anatomy and physiology. The notice of election to the Board of Examiners will be advertised in the medical journals not less than six weeks prior to the election, the candidates having to send in their applications to the secretary not less than one month prior to the election.

The mode of payment for the members of the Board of Examiners for the membership has been so arranged that each member shall receive a capitation fee of £2 for the membership and £3 for the fellowship, while the members of the Court of Examiners each receive £4 4*s.* for each candidate for the membership and £12 12*s.* for the fellowship over and above one guinea which each member of the Court receives for each attendance at a meeting. It is calculated that by this arrangement each member of the Board will receive £140 per annum for the membership and about £30 per annum for the fellowship, while the members of the Court will each receive about £200 per annum for the membership and about £45 per annum for the fellowship. But considering the small amount now received from candidates for the fellowship, and the inadequate payment to the examiners, the committee recommend an increase in the fee for the fellowship, and that immediate steps be taken to obtain a new bye-law enabling the College, in accordance with the provisions of Section 7 of the Charter of 7th Victoria, to require that a candidate for the fellowship by examination shall pay a fee not exceeding thirty guineas, over and above any stamp duty, on his admittance or diploma. Whether increasing the fees of admittance to an examination, in order to remunerate more liberally the examiners, will prove to be a wise policy remains to be seen. The Council of the College should remember that its fees are already much higher than those of any other examining board, and that raising the fees of admittance so that only the rich can pay them is not exactly the same thing as enhancing the value of the fellowship, or raising the status of the fellows. No doubt the duties of the examiners are arduous and irksome, but £200 per annum is not poor remuneration for what is done.

Nothing has yet been settled respecting the regulation of the qualifications that exempt candidates for the College diplomas from examination in anatomy and physiology.

At the same meeting of the Council, Sir James Paget read a letter on the Conjoint Scheme, inviting the various co-operating bodies to an early conference, to take into consideration again the question of the Conjoint Scheme, each body having been requested to appoint two of its members as delegates to the conference. The representatives of the College of Physicians and the College of Surgeons have already been appointed.

MEDICAL SUPERVISION OF PUBLIC SCHOOLS.

WITHIN the last three months we have had to record three serious outbreaks of enteric fever occurring in three different schools or institutions. The first was the outbreak at Müller's Orphanage Asylum, near Bristol, where, out of 2000 inmates, no less than 500 were attacked, and 12 died; the cause in this case being the casual use of water from a stream running through a valley in which the children sometimes played, and which had become contaminated by the drainage of houses situate higher up the valley. Then we have the outbreak on board the *Cornwall* school-ship, the proximate cause of the outbreak being clearly due to very distinct water contamination. And now we have the outbreak at Uppingham School, with 30 cases and 4 deaths. The investigation into the causes which led to this outbreak has to be completed, though, as we showed last week, there is strong evidence pointing towards water contamination and defective sanitary arrangements.

The head master of Uppingham, we understand, has issued a manifesto or statement in which he explains the policy adopted by himself during the epidemic. We have seen a copy of the document in question, and perused it with interest, hoping to learn from it the nature of the sanitary arrangements of the school, and the means employed to check the epidemic. But we were disappointed. It is evident the head master has, or had when he wrote the paper in question, no idea of the nature of the disease then invading the school, still less of the means by which the progress of the disease might be checked. The manifesto refers almost entirely to points of discipline, and an appeal to the moral courage of the boys during this trying period. He states, however, incidentally, that since he has been head master other epidemics have visited the school, and we would now ask him what practical lessons he has learnt from these previous outbreaks. What means are employed to prevent the introduction of infectious diseases into the school? Are the boys obliged to bring a certificate on their return from home stating that they are in good health, and have not been recently exposed to infection—i.e., not been residing in any neighbourhood where zymotic disease is prevalent? Are they examined on their return by the school medical attendant to see that they are free from disease? Are boys who fall out of school obliged to report themselves *immediately* to the medical attendant, so that if they show signs of infectious disease they are at once isolated? What precautions are taken to prevent the water-supply becoming contaminated, and what are the arrangements for cutting off and obtaining a fresh supply if cases of enteric fever occur? Have the school premises been inspected by a health officer since the last epidemic, and have all his recommendations been strictly carried out? Is the medical attendant of the school obliged to furnish half-yearly, or even yearly, a report to the head master or the authorities stating that the sanitary arrangements are complete in detail, and in perfect working order? These are questions that urgently demand an answer, and we think the public should be satisfied that every precaution has been taken before they can be asked to accept the axiom that among a large assemblage of boys it is impossible to prevent the occasional introduction of infectious disease. The experience gained by our Commission on the Sanitary Condition of Public Schools has shown that the freedom of schools from outbreaks of zymotic disease depends entirely on the excellence and thoroughness of the medical supervision, and the responsibility thrown on the medical officer of the school. Jealously guard every possible channel by which infection may be conveyed. Make the parents responsible for returning any boy in an unsafe condition to school. Treat every case of illness, however trivial, as if it were infectious, by isolation, till it has declared itself. And, lastly, frequently consult the medical officer of health of the district as to the health of the neighbourhood, the nature of the prevailing epidemics, and the special precautions to be taken in the time of danger. If these details are rigidly carried out, we maintain that school is as safe a place as home for boys, where there are no appliances or machinery for enforcing such precautions. We are anxious to learn what steps the authorities at Uppingham took to protect the boys committed to their care from the possible introduction of infectious disease, and the means employed to prevent its spread. We are the more anxious because it appears that similar outbreaks have not been infrequent in the school within the last few years.

THE FATAL OUTBREAK AT UPPINGHAM SCHOOL.

AT a meeting of the Sanitary Authorities held on Wednesday, November 3rd, at the Board Room, Uppingham, notices were ordered to be served on the head and other masters to at once remove the nuisances occasioned by the cesspits. A resolution was unanimously carried to the effect that serious blame attaches to the masters in whose houses enteric fever originated. The medical officer of the school was also blamed for not investigating the causes of the disease and not reporting the fact of the outbreak to the sanitary inspector. The Board likewise censured the medical attendant for not attending a meeting of medical practitioners in the town, convened by the medical officer of health, for the purpose of obtaining from them every information on the cause and history of the outbreak. This fact the Committee consider should be laid before the trustees of the school and the parents of all boys who had suffered. It was also resolved that a sanitary engineer be employed to report on the drainage of Uppingham, public and private, in order that steps be taken to render this as perfect as possible. Mr. Roger Field, C.E., of Wesminster, the engineer appointed, will at once proceed to Uppingham and commence his investigations in conjunction with Mr. Haviland, the medical officer of health for the district. Lastly, the medical officer of health, finding that the healthy boys were liable to be sent to the infected houses to take their meals, on his own responsibility wrote to the head master prohibiting the practice. On the following day a meeting of the trustees took place and it was resolved to close the school. The boys left on Tuesday, the 2nd inst. The sanitary authority have acted with spirit and determination, and the censures they have administered will serve as a useful warning to other offenders. With respect to the conduct of the medical attendant of the school, we should like to learn if his reticence was due to pressure put upon him by the school authorities. No fresh cases are reported, and all the boys, with one exception, are doing well. The number attacked amounted to thirty, and up to the present date there have been four deaths.

UNIVERSITY OF CAMBRIDGE.

First Annual Report to the Senate of the Syndicate appointed to superintend the Examinations in State Medicine.

The First Examination in State Medicine under the regulations confirmed by grace of the Senate, Feb. 4, 1875, was held on Oct. 5 and three following days. Twenty-eight candidates entered, of whom 26 presented themselves for examination. Four offered themselves in Part I. only, of whom one was approved. The remaining 22 were examined in both parts, and 19 of them were approved.

Two days were devoted to each part of the examination. Part I. comprised Physics and Chemistry, and their applications to sanitary matters. Part II. comprised the remaining subjects specified in the regulations—viz., the causes and prevention of epidemic and infectious diseases, the circumstances and conditions of life which are injurious to health and the laws of the realm which relate to public health. In each part two papers of questions, each of which had been submitted to all four Examiners, were set, to which written answers were required; in each part the candidates were also questioned orally by two of the Examiners sitting together, and in each part the candidates were tested by practical work.

The Examiners report that the answering was generally good, some of it excellent, more especially in questions relating immediately to the actual duties of Officers of Health. This remark applies emphatically to the reports on the sanitary condition of some of the small courts and other places in Cambridge, which the candidates were directed to visit for the purpose of inspection, each candidate having a different locality assigned to him.

The Examiners are of opinion that the number and character of the candidates are evidence that the examination supplies a public want, and may be of real service in the advancement of sanitary improvements. Such a knowledge of Sanitary Science as has been shown by the successful candidates proves them to be entitled to some trustworthy voucher for their acquirements. The University Certificate, granted after a careful and thorough examination, will be such, and may serve to assist the judgment of those Public Bodies in which the choice of Officers of Health has been invested by the law.

Every candidate was required to pay a fee of four guineas before admission to each part of the examination, and it has been found that this has been sufficient to defray all the expenses incident to the examination. The certificate is granted to those who have passed both parts of the examination without further fee.

The Syndicate considers it convenient that the holders of the certificate should be designated in a uniform manner, and recommends that their designation be "Holders of the Certificate in Sanitary Science," or abbreviated "S. Sc. Cert. Camb."

The Syndicate has arranged that the next examination shall begin on June 13, 1876, and considers it desirable to hold a second examination next year at the beginning of October. These times seem as convenient as any for the University, and are likely to suit medical men engaged in the practice of their profession. Whether it will be advisable to hold two examinations in any future year must be decided by the experience gained as to the probable number of candidates, and by other considerations.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE usual general meeting of this Society was held on the evening of Friday, the 29th ult., by the liberality of the Royal Medical and Chirurgical Society in their library. Sir George Burrows, Bart., president, took the chair punctually at half-past 8 o'clock. The attendance was very limited. Out of more than four hundred members only ten were present to support the president, and four of the ten were officers of the Society. Although it may be very complimentary to the officers, as showing how satisfied the members are with the management, still it would be more gratifying to them if the members would attend at the general meeting and manifest an interest in the working of the Society.

From the half-yearly statement of accounts read, it appeared that, during the last half-year 58 widows and 20 children had received grants amounting in the aggregate to £1236 10*s.*; the expenses had been £130 11*s.* 5*d.*, which sum included the cost of the circular in the beginning of the year to all members of the profession eligible to become members of the Society. The total receipts of the half-year available for payments had been £1598 10*s.*, and the payments £1367 1*s.*, leaving a balance of over £200. A legacy of £1500, less duty, had been received from the executors of Alexander Barker, Esq., and a legacy of £100, less duty, from the executors of T. F. Chilver, Esq., a member of the Society, and another legacy was reported of £1000, duty free, from the Rev. H. C. Morgan.

Sir Thomas Watson and Dr. Billing were elected vice-presidents in the places of Dr. Latham and Sir Charles Locock, both deceased; and Mr. Streatfeild was elected a director in place of the late Mr. Sercombe.

It was announced at the meeting that the directors intended, out of the balance in hand, to make a present at Christmas of £4 to each widow, £1 10*s.* to each child, and £2 to each of the recipients from the Copeland Fund.

THE CAUSATION OF DICROTISM.

To the Editor of THE LANCET.

SIR,—In his valuable lectures on the Pulse recently published in THE LANCET, Dr. Broadbent has touched upon a question which has long been a vexed subject of controversy—namely, the Causation of Dicrotism. The point at issue does not indeed affect the practical inferences from the pulse-curve with regard to arterial tension and distensibility which he has so lucidly set forth. A correct explanation of dicrotism must, however, conduce to a clear comprehension of the different varieties of pulse, and I therefore regret that so high a sanction should be given to a theory which I believe to be not only mechanically impossible, but directly contradicted by observation.

Dr. Broadbent explains the second expansion in the pulse as caused simply by the elastic recoil or contraction of the aorta when relieved from the pressure of the blood, so that in the aorta itself no second expansion or dicrotic wave occurs at all. It is an explanation which was, I believe, first put forward by Dr. Mahomed. In all theories of dicrotism, the elasticity of the arteries is, of course, regarded as a necessary condition for its production, but, according to this view, we must suppose that, as we trace the pulse-wave downwards towards the legs, there is a point—namely, the bifurcation of the aorta—above which no second expansion takes place, while below it there is a second expansion due to the elastic contraction of the aorta above. Reasoning based upon the principles of mechanics is apt not to be universally understood or appreciated, and therefore it is a fortunate circumstance that, in this case, the theory can be put to the direct test of observation, whether or not a second expansion does occur in the aorta. We know that in the femoral arteries the dicrotic wave is well marked, and it is not unfrequently possible to obtain a tracing from the abdominal aorta when it has undergone aneurismal dilatation, or pulsates excessively from nervous causes. The dicrotic wave is always found in the trace, and in the latter case the form of the pulse-curve is not very different from that of the femoral artery. Again, pulsation is occasionally produced in the upper intercostal spaces by a condition which is found after death to be not an actual aneurism but a general aneurismal dilatation of the arch of the aorta. The tracing then obtained from the point of pulsation may be expected not to differ widely from the normal aortic tracing. In more than one instance of this kind I have found the curve to resemble closely that obtained from the radial pulse when the arteries are very atheromatous, and to show a distinct second expansion. Lastly, similar evidence may be obtained from experiments on animals. Marey has published* a curve, obtained by means of the polygraph, representing the pressure within the aorta of a horse, and the dicrotic wave is here seen, and shown to be synchronous with the closure of the aortic valves, although in this instance it is comparatively small. In this and in all other aortic tracings the dicrotic wave differs from that seen in the radial pulse, just as the latter in its turn differs from the dicrotic wave in a more distant artery, such as the dorsalis pedis, by the fact that its ascent is more abrupt, and its maximum is reached much earlier. I think that the evidence thus afforded of the occurrence of a second expansion in the aorta itself is sufficient to narrow the question of the causation of dicrotism by the exclusion of the theory adopted by Dr. Broadbent.

I am, Sir, your obedient servant,
St. Thomas-street, Oct. 27th, 1875. A. L. Galabin.

DR. HARDWICKE.

To the Editor of The Lancet.

Sir,—With reference to a paragraph which has recently appeared in the daily press headed "Contempt of a Coroner's Court," I wish to make the real facts of the case known.

1st. I received no notification, either verbal or written, that the inquest was going to be held.

2nd.—I know perfectly well that no fee is allowed in such cases, as I have given evidence before.

3rd.—I have never heard any complaint with reference to fees from any member of the resident staff.

Apologising for troubling, I enclose my card, and am, Sir,
Your obedient servant,
The House-Surgeon.
University College Hospital, Nov. 4th, 1875.

*** As we expected, our correspondent has triumphantly vindicated himself and his colleagues. It will be seen that we have dealt with the matter in another place.—Ed. L.

BIRMINGHAM.

(*From our own Correspondent.*)

The Queen's Hospital is to be congratulated on having achieved two great successes this week. "Hospital Sunday" bids fair to equal, if not to surpass, any of its predecessors, the amount already announced, as collected yesterday, being upwards of £4000; but the greater and more important achievement is the adoption of the "free system," which was carried to-day by a large majority at one of the largest meetings of governors ever held. The subject was discussed by the governors on the 9th of July last, in consequence of the report of a sub-committee specially appointed to inquire into the best means of improving the financial state of the institution, and an adjournment took place till Nov. 1st in order that the governors might have the fullest information before instituting any fundamental change in the admission of patients. The report of the sub-committee, which was to-day adopted, abolishes every vestige of the privilege system, and leaves the committee and medical staff free to admit what patients are most suitable; establishes a registration fee of one shilling for each patient, such fee to be remitted in cases of accident or extreme indigence; and ensures the fullest inquiry by competent officers into the social fitness of all applicants for hospital relief. When one considers that, out of 5170 in-patients and 42,304 out-patients who have been attended to at the Queen Hospital during the last three years, 4000 in- and 16,000 out-patients were admitted without tickets, as accidents or urgent medical cases, one is not surprised to find the governors have seen the uselessness of perpetuating the privilege system, and that they have by their present action decided that in future there shall, between the hospital and the sick and suffering poor of Birmingham, be no barrier in the shape of any ticket of admission. Great credit is due to the committee for so energetically pursuing a course which at one time was regarded with hostility by some few of the governors, and by some representatives of the working class, and for carrying it to so successful an issue, and it is to be hoped their example will be followed by the committees of many other medical charities which at present groan under the disadvantages of the privilege system.

At their last meeting the corporation unanimously decided to purchase the property of the waterworks company, and thus to control the water-supply of the town and adjacent neighbourhood. This property, which might have been purchased in 1851 for £250,000, will now cost the town £1,360,000—a vast sum truly, but probably not too much for the great outlay of capital involved in the supply of water to a population of 500,000 people, and certainly public money can be spent in no better way than in providing an ample supply of the purest water that can possibly be obtained. The corporation also decided to expend £1000 in planting trees in some of the public streets, on the ground that such trees would not only improve the appearance of the thoroughfares, but would also be useful in a sanitary point of view.

The annual meeting of the Governors of Queen's College was devoid of special interest, except for the attempt of the Mayor to reopen the question of the admission of female students, which, however, was of no avail, as the council had decided to abide by their former resolution, and therefore the Mayor, with some warmth, withdrew his proposition for reconsideration of the subject.

The report of the Orthopædic Hospital is satisfactory. 759 cases have been treated during the year at a cost of £443. A suitable building has not yet been found, but probably the funds are better expended in instruments and drugs than they would be in keeping up a costly in-patient department.

The thirtieth annual meeting of the Dudley Dispensary was recently held, when the report of the Committee showed that the institution was flourishing, 3804 patients having received medical aid during the year, and the funds having proved ample for their wants.

Birmingham, Nov. 1st, 1875.

PARIS.

(*From our own Correspondent.*)

ANNUAL MEETING OF THE FIVE ACADEMIES.

The annual meeting of the five Academies constituting the Institute of France took place on the 25th ultimo, at the Palais Mazarin. The meeting was this year presided over, according to rotation, by a member of the Academy of Fine Arts, but the great biennial prize given away every year by one of the Academies "to the work or discovery most highly calculated to honour or serve the country," belonged this year in turn to the Academy of Sciences. It has been given, with the necessary consent of all the other Academies, to Dr. Paul Bert, Professor of Physiology at the Sorbonne, and a deputy in the National Assembly, for his labours and published work "On the Influence of Barometric Pressure on the Phenomena of Life."

The President, in mentioning Dr. Bert's name, accompanied it with the following flattering remarks, which show in what high estimation he is held here:—"In giving such a reward to the varied and ingenious experiments of M. Paul Bert, to his long and useful researches carried on during several years under difficult circumstances, you have, gentlemen, to speak like the Academy of Sciences represented by one of its most illustrious members—Claude Bernard,—you have, I say, highly manifested the interest which you attach to the progress of pure science, to *true scientific discoveries.* They are always fertile, but it is for time to develop and ripen their consequences. The discoveries of M. Paul Bert bear that eminently scientific character of severity and precision which, even at present, places them in the first rank amongst the greatest physiological discoveries of our epoch."

PROFESSOR LORAIN.

Many touching and interesting anecdotes are related of Professor Lorain, whose sudden death has been the universal subject of conversation and regret during the last few days. The circumstances under which he died were most unfortunate, whilst they showed his devotion to the duties of humanity. He was busy in his study preparing his first lecture on the History of Medicine, which he was to deliver in a few days (to-morrow, Wednesday), when a patient called to ask him to attend a child. The servant had received orders to say, "Not at home," but the poor father insisting, she let him in, and Dr. Lorain, notwithstanding his wife's reminder that he was not well, went out, took an open carriage, and climbed the six flights of stairs which led to the sick child. He had scarcely reached the room when he begged to be laid on a bed, and asked that his wife should be sent for. Two medical men came in and found him blue in the face and convulsed, and in about twenty minutes he was no more.

As a proof of the extraordinary effects which sometimes attend severe regulations it is related that Dr. Grancher (one of the medical men who attended the unfortunate Professor) went to the "bureau" of St. Antoine Hospital to get a stretcher whereupon to take the body to his home. The official of the bureau sternly refused to let a stretcher be taken out of the hospital, the regulations being formal on the subject, and though Professor Lorain had been ten years physician to the hospital and was at the time physician to La Pitié, his friends had to apply to another establishment to get the necessary stretcher.

Lorain is most deeply and sincerely regretted here, and his death is considered a veritable loss to science. From college life to his high post as Professor, throughout all his *concours* and in all the posts which he occupied, Lorain made himself loved and esteemed. All who knew him liked him for his amiable, frank, loving character, and esteemed him for his upright and noble mind.

Amongst the anecdotes which are related of him I cannot resist the satisfaction of mentioning the two following.

During the Commune Lorain had been affected, at his small country-place of Azay le Rideau, with symptoms of intestinal strangulation. Having returned to Paris too soon afterwards, partial peritonitis supervened. Lorain kept quiet at home and did not dare to expose himself to the jolting of a carriage-drive. It was under these circumstances that his friend Sainte-Claire Deville, the celebrated Professor at the Museum, got a telegram one day informing him that his son was dangerously ill at Nantes. He had no time to lose, and he despatched a friend to Lorain to show him the telegram and ask his advice. The next morning, Lorain, forgetting his own sufferings and the danger he exposed himself to, was in Nantes at the bedside of his friend's child, whom he was really the means of saving by the measures which he ordered.

In 1868 Lorain, who was known to M. Duruy, the Minister of Public Instruction, was inscribed on the list of savants who were to receive the Cross of the Legion of Honour. He heard of this, and at once went to Sainte-Claire Deville and entreated him to use all his influence with the Minister so as to get the name of an elder colleague of his substituted for his own. This was done, and Lorain had to wait seven years before receiving the wished-for Cross for himself, as he obtained it only in August, 1875.

Paris, 2nd Nov., 1875.

Obituary.

JOHN HAMILTON, F.R.C.S.I.,

SURGEON-IN-ORDINARY TO THE QUEEN IN IRELAND.

With great regret we announce the death of this member of the profession, which occurred at his residence in Merrion-square, Dublin, on the 2nd inst., aged 66. Mr. Hamilton suffered, we understand, from malignant disease of the rectum, with a communication between the bowel and the bladder; and Mr. Curling performed the operation of colotomy on Sunday, the 10th ult. The deceased was a pupil of the late Sir Philip Crampton, and shortly after obtaining his diploma was appointed surgeon to the Richmond Hospital, which post he held until within the last few months. During this year he was selected as surgeon in ordinary to Her Majesty, and Vice-president to the Royal College of Surgeons. He was surgeon to St. Patrick's Hospital for Lunatics and Imbeciles, Medical Examiner to the Customs, and was a member of various scientific and medical societies, including the honorary membership of the Paris Chirurgical Society, Corresponding Member of the National Institute, Washington, and Consulting Surgeon to St. Mark's Ophthalmic and the Richmond Hospitals. Mr. Hamilton was a very skilful surgeon, and held a high position in Dublin, being esteemed for his goodness of heart and benevolence of character, which were accompanied by professional abilities of no mean order.

WM. RALEIGH BAXTER, LL.D., L.K.Q.C.P.I.

We have to record the death of the above-named gentleman, which took place suddenly at Emsworth on the 11th ultimo, from syncope consequent on an attack of diabetes mellitus, from which he had been suffering for more than twelve months. As a medical man he stood high in the profession; he was an able and skilful practitioner, and his abilities were testified to not only at home but abroad by the number of honorary distinctions conferred upon him. He held the LL.D. (honoris causâ) from King's College, Aberdeen, and also diplomas from the Imperial Society of Medicine, Constantinople, and other kindred societies. For many years he was the editor of the *Medical Record*, and was also the author of "A Treatise on Certain Abnormal Sounds of the Heart," "Handbook of Chemistry," &c. Previous to settling in Emsworth, where he practised with a short interval for thirty-three years, he was a lecturer in the Dublin and London schools on Materia Medica; and his testimonials from distinguished members of the profession, some of whom are still living, bear ample evidence of the zeal and ability which he displayed as a teacher. On the outbreak of the Crimean war, Dr. Baxter formed one of the band of volunteers who sacrificed the comforts of home and remunerative practice to follow the fortunes of our army in the East. He was attached to the Osmanli Horse Artillery, and the manner in which he performed the arduous duties of senior regimental surgeon to that corps drew forth the praises of his senior officer, Surgeon Major R. R. Alderson. At the conclusion of the war he resumed his practice at Emsworth, which in his absence had been carried on by his brother, and which he continued until death put an end to his earthly career. In addition to his professional duties, Dr. Baxter found time to write for many of our leading lay journals. His death will be much felt in Emsworth and the surrounding neighbourhood, where he was always doing good.

PROFESSOR LORAIN.

One of the most brilliant and distinguished professors of the Paris Faculty, Dr. Paul Lorain, has just suddenly ended this life. On the morning of October 25th he felt rather unwell, when one of his poor patients, inhabiting a sixth storey in the Faubourg St. Antoine, prayed him to call and see a member of his family. Dr. Lorain hesitated, but on his sister's pressing him he consented. On going up the poor man's stairs he felt sadly uncomfortable, and on reaching the landing-place he sighed, lost consciousness, and in a few seconds was no more. He was a strongly built man, of florid complexion, and for years already had been obliged to follow a severe regimen, excluding wine, and taking a great deal of walking exercise.

Dr. Lorain was only forty-eight years of age, and was appointed three years ago to the chair of History of Medicine, left vacant by the death of Daremberg. He was most extraordinarily intellectual, and highly gifted, and was successful in whatever branch of medicine he took up, or took to, according to circumstances. Thus, he was one of the most earnest and brilliant representatives of the physiological or scientific school of medicine, and formed one of the group of admirers who surrounded Marey, and applied his useful inventions to the investigation of disease.

Lorain's works on the pulse &c., containing researches carried on with the sphygmograph, the thermometer, the hæmodynamometer, and other scientific means of diagnosis and prognosis, are most valuable clinical studies; and, indeed, Lorain, who was physician to the Pitié Hospital, was generally quoted as an accomplished clinical investigator and teacher. His reports on various questions of forensic medicine when he happened to be nominated an expert are most remarkable for acuteness of observation, soundness of judgment, and elegance of style. He was equally eminent in his theoretic teaching at the Faculty, and his lectures were amongst the best attended.

Lorain was most popular amongst the profession, the public at large, and especially the quarter of the town which he inhabited, and in which he was so much liked on account of his kindness and liberality to the poor. His warmth of heart, cheerfulness of spirit, and refined artistic mind endeared him to all who knew him, and his rapid success excited no jealousy, as he was amongst the most ardent and laborious workers of his day.

MICHAEL HARRIS, M.B. Lond.

On Sept. 28th died, at Manchester, Michael Harris, M.B. Lond., assistant-physician to the Children's Hospital, Pendlebury, in the twenty-seventh year of his age. By his early death a career of much promise has terminated. After a period of studentship, marked by industry and ability, at Guy's Hospital, where he held the offices of house-surgeon and house-physician, he graduated M.B. in the University of London in 1872, obtaining honours in Midwifery and the first place and the gold medal in Medical Jurisprudence. Subsequently he was appointed Demonstrator of Anatomy in the Liverpool School of Medicine, and discharged his duties zealously and successfully. Lately he removed to Manchester, and had been appointed assistant-physician to the Children's Hospital only a few days before his decease. His upright character and kind and genial disposition endeared him to a large circle of friends in the profession.

Medical News.

Royal College of Physicians of London. — At a meeting of the College on Oct. 28th the following gentlemen were admitted Fellows:—

Adey, Charles Augustus, M.D. Edin., St. Leonard's.
Burder, George Foster, M.D. Aberd., Clifton.
Corfield, William Henry, M.D. Oxford, Bolton-row.
Falls, William Stewart, M.D. St. And., Bournemouth.
Fearnside, Henry, M.B. Lond., Preston.
Matterson, William, M.D. St. And., York.
Mounckton, Stephen, M.D. Lond., Maidstone.
Montgomery, James Barclay, M.D. Glasg., Penzance.
Ord, William Miller, M.B. Lond., Brook-street.
Semple, Robert Hunter, M.D. St. And., Torrington-square.
Shepherd, Augustus Burke, M.B. Oxford, Seymour-street.
Thorne, Richard Thorne, M.B. Lond., Inverness-terrace.
Tuke, Daniel Hack Tuke, M.D. Heidelberg, Falmouth.

At the same meeting the following gentlemen were admitted Members:—

Herman, George Ernest, Bethnal-green Infirmary.
Leech, Daniel John, M.B. Lond., Manchester.

Also, the following were admitted Licentiates:—

Chapman, Paul Morgan, Camden-park-road.
Dyte, David Hyman, Bury-street.
Gibb, Robert Charles, Guy's Hospital.
Harvey, Thomas Prickard, Pyrland-road.
Herman, George Ernest, Bethnal-green Infirmary.
Hobson, John Morrison, Guy's Hospital.
Lancaster, Henry Francis, Amersham-park Villas.
Randle, James Mayne, Guilford-street.
Rawlings, Alfred, Newlands, Sherborne.
Taylor, Henry Cumberland, Guy's Hospital,
Weakley, Samuel Joseph John, Upton, Essex.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Oct. 28th:—

Bark, John, Royal Infirmary, Liverpool.
Harvey, Henry Frederick, Gower-street.
Morcom, Augustus, Coniston, Lancashire.
Taylor, James, Stokes Croft, Bristol.
Williams, William Venables, Easingwold, Yorkshire.

The following gentleman passed the Primary Professional Examination on the same day:—

Capon, Herbert James, St. Bartholomew's Hospital.

An outbreak of scarlatina is reported to have occurred at Acomb Colliery.

H. T. Harvey Mead, M.R.C.S., &c., has been elected Mayor of Christchurch for the ensuing year.

The total number of students entered up to this date at the Liverpool Royal Infirmary School of Medicine is 103; of these 23 are first year's men.

Mr. George Stevens, of Norton, Bury St. Edmunds, F.F.P.S. Glasgow, is a candidate for the vacant coronership of the county of Suffolk.

The Entrance Scholarships of Guy's Hospital Medical School have been awarded as follows:—L. C. Wooldridge, £60; W. H. White, £30; J. T. J. Morrison, Honorary Certificate.

Surgical Society of Ireland.—The following office-bearers have been appointed for the ensuing year:—President: Edward Hamilton. Vice-President: John Hamilton. Council: John Barker, E. H. Bennett, Charles Benson, Philip Bevan, Richard G. H. Butcher, William Colles, A. H. Corley, Henry Gray Croly, J. Stannus Hughes, Rawdon Macnamara, Edward Dillon Mapother, Benjamin Francis M'Dowell, John Morgan, George H. Porter, Michael Harry Stapleton, William Stokes, Joliffe Tufnell, Albert J. Walsh, James H. Wharton. Honorary Secretaries: B. Wills Richardson, Humphrey Minchin.

The visiting justices of the County Gaol, Bedford, have recommended that a superannuation allowance of £86 13*s.* 4*d.*, being two-thirds of his salary, be granted to Mr. Robert Couchman on his resigning the office of surgeon.

George Walker, Esq., M.R.C.S. Eng., L.S.A., Raithby, near Spilsby, and William H. Eddie, Esq., M.R.C.S. Eng., L.S.A., Barton-on-Humber, have been placed in the Commission of the Peace by the Lord Lieutenant of Lincolnshire.

Health of Dublin. — From the Report of the Registrar-General for Ireland for the September quarter, we learn that the registered births amounted to 2246, or at the rate of 29 in every 1000, and the deaths to 1705, affording an annual ratio of 1 in 46 or 22 in every 1000 of the population. The principal causes of death were as follows:—Phthisis caused 207 deaths; convulsions, 155; diarrhœa, 140; bronchitis, 105; heart-disease, 85; fever 51; cancer, 47; pneumonia, 47; whooping-cough, 45; apoplexy, 41; paralysis, 40; measles, 38; mesenteric diseases, 36; hydrocephalus, 34; liver disease, 34; whilst 39 deaths resulted from accidental causes, 1 was homicidal, and 3 suicidal. The mean weekly temperature for the quarter was 58·9°, and the rainfall during the thirteen weeks measured 8·532 inches.

Richmond Water-supply.—At a special meeting of the Richmond Select Vestry, on Wednesday morning, a letter was read from the Local Government Board, sanctioning the borrowing of £28,000, for the purpose of obtaining a local water-supply. It was proposed by Dr. T. F. Giles, and seconded by Dr. Kenny, that application be immediately made to the Public Works Loan Commissioners for the required sum, at 3½ per cent., repayable in thirty years. On a division, the motion was carried almost unanimously. It is intended to sink a deep well into the chalk and to have a large covered reservoir in Richmond-park. The Crown authorities have already sanctioned the construction of the reservoir, and Mr. Hawkesley, C.E., Mr. Prestwich, and other gentlemen have given it as their opinion that an abundant supply of water will be obtained from the chalk basin underlying Richmond.

Medical Appointments.

Archer, R. K., M.R.C.S.E., L.S.A.L., has been appointed House-Physician to the Westminster Hospital, vice Basham, resigned.

Blythman, C. S., M.B., C.M., M.R.C.S.E., has been appointed Medical Officer of Health for the Swinton Urban Sanitary District.

Cheadle, W. B., M.D., F.R.C.P.L, has been appointed Physician to the Hospital for Sick Children, Great Ormond-street.

Clarke, T. F., M.D., M.R.C.S.E., has been appointed Medical Officer for the Bradninch District of the Tiverton Union.

Devany, P. C., L.R.C.P.Ed., L.R.C.S.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the No. 2 Division of the Sligo Dispensary District, Sligo Union, vice Tucker, deceased.

Finlay, D. W., M.D., C.M., has been appointed a Resident Physician's Assistant at the Middlesex Hospital, vice Lucas, whose appointment has expired.

Garbutt, J. G., M.A., has been appointed Demonstrator of Anatomy at St. Mary's Hospital.

Hepburn, W. J., F.R.C.S.Ed., L.R.C.P.Ed., L.K.Q.C.P.I., has been appointed Medical Officer for the South City District of the Irish Mercantile Clerks' Association, Dublin.

Holthouse, C, F.R.C.S.E., has been appointed a Consulting Surgeon to the Westminster Hospital, on resigning as Surgeon.

Johnson, H., M.D., Ext. L.R.C.P.L., has been appointed Visitor of Houses licensed for the reception of Lunatics in the County of Salop.

Kenny, E. J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the North City District of the Irish Mercantile Clerks' Association, Dublin.

Lawrie, J. D., M.R.C.S.E., has been appointed a Surgeon to the Infirmary and Dispensary, Bradford, Yorkshire, vice M'Gee, resigned.

Lees, D. B., M.B., has been appointed an Assistant-Physician to the Hospital for Sick Children, Great Ormond-street.

Lovett, S. R., L.R.C.P.Ed., L.M., has been appointed Medical Officer of Health for the St. Giles and St. George District, vice Ross, deceased: £150 per annum.

Macnamara, C. N., F.R.C.S.E., has been appointed a Surgeon to the Westminster Hospital, vice Holthouse.

Madeley, E., M.R.C.S.E., has been appointed House-Surgeon and Dispenser to the Provincial Hospital at Port Elizabeth, Cape of Good Hope.

Markby, T., M.R.C.S.E., has been appointed Medical Officer for the No. 5 District of the Royston Union, vice Balding, resigned.

Mason, J. W. B., M.R.C.S.E., has been appointed Resident Obstetric Assistant at the Middlesex Hospital, vice Beaumont, whose appointment has expired.

North, J. C., M.B., C.M., has been appointed Medical Officer (*pro tem.*) to the Brecknock Union Workhouse.

Richardson, R. I., M.B., C.M., has been appointed a Resident Surgeon at the Maternity Hospital, St. John-street, Edinburgh.

Russell, V. W, L.K.Q.C.P.I., L.R.C.S.I., L.M., has been appointed Surgeon to the County Tipperary Infirmary, Cashel, vice R. F. Russell, M.B., L.R.C.S.I., resigned.

Sargent, A. F., M.R.C.S.E., has been appointed Junior House-Surgeon to the Tunbridge Wells Infirmary.

Saville, J. G., L.R.C.P.Ed., L.M., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the Radcliffe District of the Bury Union, Lancashire, vice Sellers, resigned.

Scott, T. H., L.R.C.P.Ed., L M., L.R.C.S.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Ballina Dispensary District of the Ballina Union, Co. Mayo, vice Macnamara, resigned.

Snell, E. G. C., L.S.A.L., has been appointed Medical Officer to the Permanent Life Assurance Company (Eastern District).

Strugnell, F. W., M.R.C.S.E., has been appointed House-Surgeon to Queen Charlotte's Lying-in Hospital.

Sutcliff, E., M.D., L.R.C.P.L., M.R.C.S.E., Medical Officer for the Peters-Marland District of the Torrington Union, has been appointed also Public Vaccinator.

Thomson, W. A., F.R.C.S.I., L.K.Q.C.P.I., has been appointed Second Assistant Medical Officer to the Surrey Lunatic Asylum, Brookwood.

Valentine, E. W., M.R.C.S.E., L.M., has been appointed Medical Officer for the 2nd Division of No. 4 District of the Shepton-Mallet Union, Somersetshire, vice Macdonald, resigned: £20 per annum and fees.

Walker, T. O., M.R C.S.E., has been reappointed Medical Officer and Public Vaccinator for the Crick District of the Rugby Union.

Williams, W. E., M.R.C.S.E., has been appointed Medical Officer of Health for the Bedwellty Rural Sanitary District: £40 for one year.

Wyllie, J., M.D., F.R.C.S.E., M.R.C.S.E., has been appointed Pathologist to the Royal Infirmary, Edinburgh, vice Pettigrew, appointed Professor of Medicine at the University of St. Andrews.

Births, Marriages, and Deaths.

BIRTHS.

Barwell.—On the 25th ult., at George-street, Hanover-square, the wife of Richard Barwell, F.R.C.S.E., of a son and a daughter.

Biddle.—On the 28th ult., at Kingston-on-Thames, the wife of Daniel Biddle, M.R.C.S.E., of a daughter.

Bushell.—On the 8th ult., at the British Legation, Pekin, the wife of S. W. Bushell, M.D., of a son.

Maffey.—On the 27th ult., at Clarendon, Bradford, Yorkshire, the wife of John Maffey, L.R.C.P.Ed., of a daughter.

Mercer.—On the 26th ult., at Tudor Lodge, Brixton, the widow of John T. Mercer, M.B., of a daughter.

Ridge.—On the 31st ult., at Carlton House, Enfield, the wife of John Jas. Ridge, M.D., of a son.

Titley.—On the 27th ult., at Brigg, the wife of James Titley, M.D., of a daughter.

MARRIAGES.

Bateson—Johnson.—On the 7th ult., at St. John's, Ellel, near Lancaster, Robert Sander Bateson, M.R C.S.E., Surgeon-Major Indian Army, to Elizabeth, daughter of Dr. Johnson.

Duke—Mellersh.—On the 27th ult., at St. George's, Hanover-square, Stephen Duke, M.D., M.R.C.S., L.S.A. (second surviving son of the late Henry Duke, Esq., of Earnley House, Chichester), to Harriet Elizabeth (Lilly), only surviving child of the late Thomas and the late Harriet Sophia Mellersh.—No Cards.

Wegg—Rickards.—On the 28th ult., at St. James's, Westminster, William Wegg, M.D., to Mary Ann, daughter of the late Samuel Rickards, Esq.

DEATHS.

Allarton.—On the 29th ult., at South Molton, Geo. Allarton, M.R.C.S.E., aged 62.

Badger.—On the 23rd ult., at Sydenham, Wildsmith Badger, L.S.A.L., formerly of Gutter-lane, Cheapside.

Bennett.—On the 30th ult., at Oxford-street, W., Thos. Tyrwhitt W. Bennett, Surgeon, aged 56.

Cross.—On the 26th ult., at Caledonia-place, Clifton, Wm. Cross, F.R.C.S.E., aged 65.

Green.—On the 29th ult., at Parliament House, Peckham, Dr. Marryat H. Green, aged 22.

Hamilton.—On the 2nd inst., John Hamilton, F.R.C.S.I., of Merrion-square North, Dublin.

Smart.—On the 25th ult., at the residence of her father, Celia Elizabeth, wife of Bath Charles Smart, M.D., of Great Ducie-street, Strangeways, Manchester, and daughter of Daniel Gurteen, Esq., J.P., of Haverhill, Suffolk, aged 36.

Steel.—On the 20th ult., at Northgate, Baildon, Yorkshire, James Steel, M.R.C.S.E., aged 64.

Stuart.—On the 21st ult., Dr. Robt. Stuart (son of Dr. Stuart, of Woolwich), aged 30.

Wilby.—On the 28th ult., at Leicester, J. B. Wilby, L.R.C.P.L., aged 38.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

THE SCHOOL OF MEDICINE OF PARIS.

THIS school is not yet supplied with a Dean. The difficulties mentioned in a recent letter of our Paris correspondent still subsist, on account of the reluctance of the various professors to assume the responsibilities and irksome duties of the post. Professors Gosselin, Depaul, and Vulpian have already refused. Meanwhile the present (ex-) Dean, who sent in his resignation several months ago, is most anxious to get away, and remains in office only because he is most warmly solicited by the Minister of Public Instruction. M. Wallon (the Minister), making the most of the interregnum which is thus established, has sent in to the professors various plans of reform in connexion with the Deanship. Some of these measures had been suggested by the present (ex-) Dean, M. Wurtz. A Commission has been appointed by the professors to consider them, and report to the Minister. If adopted, they will have the excellent effect of lessening the numerous and absorbing duties of the Dean, or rather of dividing them between that officer and his two assessors, who until now had only the office of representing the Dean during his absence, but who in future would have really active administrative and academical duties to perform. The increasing number of students (now amounting to about 4800) renders some such measure of reform absolutely necessary. At present it is calculated that not less than 5000 to 6000 "affairs," or "pieces of business," annually pass through the hands of the Dean. Various other measures of reform in connexion with the teaching of the school are also being examined by the professors.

Mr. Hugh Barton should make his complaint to the Commissioners in Lunacy.

PURPURA HÆMORRHAGICA.

To the Editor of THE LANCET.

SIR,—Seeing a case of purpura hæmorrhagica reported in your journal of Oct. 16th, I think perhaps you may consider it worth while to publish the notes of the following somewhat similar case.

Mary M——, aged twenty-one, a domestic servant, was admitted into the hospital on June 3rd, 1875, under the care of Dr. Elliott. She states that prior to ten months ago she was a healthy girl, but that about that time she began to suffer from "ulceration of the nose." Since then she has never been well, but has suffered much from languor and weakness. In March last she first began to have attacks of epistaxis, at first only slight and at long intervals; but lately they have much increased in severity, and these constantly recurring attacks of epistaxis were the cause of her applying here for treatment. There is no family history of purpura or any other kind of hæmorrhage.

State on admission.—Fairly nourished; very anæmic; gums spongy, and often bleed; faint anæmic murmur over base of heart; one or two purpurous spots on legs; other viscera healthy; menstruation natural. She was ordered ten minims of tincture of perchloride of iron and ten minims of tincture of ergot three times a day. During the first two or three days she had only very slight hæmorrhage; but on June 9th very severe epistaxis came on, and the posterior nares on the right side was then plugged. The plug was removed on the third day, and she had no return of the epistaxis. Still, however, there was occasional oozing of blood from the gums. She was discharged on June 20th in a much improved state of health.

The patient again took a situation as domestic servant, and continued there until July 30th, when she was readmitted here on account of a recurrence of the epistaxis. She was in a very feeble condition, having had a furious attack of epistaxis the day previous. The gums were pale, and constantly oozing; the conjunctivæ were bloodless, but there were no purpurous spots on her limbs. She was ordered ten minims of solution of pernitrate of iron with fifteen minims of tincture of ergot in water, and liberal diet. After her second admission she had no severe attack of epistaxis.

Aug. 8th.—As the gums were constantly oozing blood, she was ordered a wash of borax and myrrh.

14th.—A lotion of glycerine and tannic acid was ordered for the mouth.

18th.—A severe attack of menorrhagia occurred, and she was ordered in consequence ten minims of sulphuric acid, ten grains of gallic acid, with infusion of roses: one drachm to be taken every four hours. This for a short time restrained the hæmorrhage; but it recurred on the 23rd, and she was consequently ordered half a drachm of bromide of potassium and twenty minims of tincture of ergot in water every three hours.

24th.—At eight P.M., the hæmorrhage being very severe, the vagina was plugged, and a hypodermic injection of solution of ergotine (six minims) was administered.

27th.—The plug was removed, and, an hour or two after, the hæmorrhage recommenced. A speculum was introduced, and as blood was seen to be issuing from the os uteri, it was plugged with a pledget of lint dipped in strong perchloride of iron, the injections of ergotine being continued twice a day.

During all this time she had been gradually getting weaker, and the blood had become very watery in character.

29th.—Plug removed, vagina syringed out with a lotion of Condy's fluid, and the plug reintroduced.

Sept. 1st.—Diarrhœa came on, and lasted until she died on Sept. 4th.

No post-mortem was allowed.

I remain, Sir, yours &c.,
HENRY THOMPSON, House-Surgeon.
Hull General Infirmary, Oct. 26th, 1875.

Juvenis.—It would seem desirable that a mutual understanding with regard to such patients should be arrived at. The distance is so considerable between the two places that our correspondent would in the eyes of most men be justified in attending when called upon to do so.

Mr. H. B. Hewetson is thanked for his offer.

THE SCHOOL BOARD AND INFECTION.

THE circumstance that the School Board in the metropolis compels poor parents to send their children to its schools, and enforces obedience to its commands with a pertinacity little short of tyrannous cruelty, should induce the officers of this inquisitorial Board to bestow some care on its victims. A case which came before the coroner for Central Middlesex on Monday does not certainly convey the impression that the Board is properly alive to this part of its public duty. A child, with suppressed scarlet fever, was proved to have been in attendance among hundreds of little ones congregated under the ferule of the law, up to the day before its death. It is not a pleasant reflection that probably this poor child infected others. The feeling rapidly growing among the poor—who are in no way averse to having their children instructed if that can be accomplished in mercy as well as "charity"—is not one of gratitude. The sternness of too many of the Board officials, and the curt justice of justices, are sufficiently irritating. If the Board schools are to be left wholly without medical inspection, and allowed to become hot-beds and centres of disease, the net gain to civilisation will scarcely prove a recompense for all the toil and expenditure lavished on national education.

Mr. C. R. Priestley shall receive an answer next week.

THE INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—It may be interesting to some of your student readers who intend becoming candidates for the Indian medical service to know what is the real state of affairs out here before they do so, as the prospectus supplied from the India Office gives a very erroneous idea of it, and when we get out to this country we are greatly disappointed.

Instead of giving the full pay laid down in the schedule, when we pass the required examination in Hindustani and get charge of a native regiment, they keep us moving from place to place, drawing unemployed pay a great part of the time, and paying our own expenses by rail or road. When we take up an active appointment, we hold it such a short time that the half allowances which we draw are often insufficient to cover the expense incurred in taking it up. As a rule we do not draw full pay until we have served three and a half or four years; and when our furlough becomes due we can scarcely afford to take it, as we only get half-pay while on leave, and have to find our own passage home and out again. If we be put in charge of a wing of a native regiment, it is still worse: we only get 75 r. a month in addition to our unemployed pay. There is quite as much work and responsibility when we act as when we hold a permanent appointment; but, as the pay is much less, they carefully avoid mention of such in the schedule. When ordered to take up one of these wretched billets from unemployed pay, we have to pay our expenses, as we are supposed to be bettering ourselves, and they take good care that we are on unemployed pay, lest they should have to pay our railway fare.

The pensions are miserably small, and there is nothing good to be looked forward to in this service at present. The pension of £220 a year is not sufficient to support a bachelor in moderate comfort, and we have to serve seventeen years for it. Even the largest pension which a surgeon-major can obtain after thirty years' service and upwards is a very poor reward for the life of toil, self-denial, and discomfort he is obliged to lead here. A deputy surgeon-general of more than four years' service in that grade may also have to retire on the same—viz., £550 per annum—on account of illness or age.

There is favouritism carried on in some places; and one often finds a native or half-caste, who has been educated at one of the Colleges by the Government, put into a good appointment, when a more senior and more deserving man should have got it.

It is easy for some of those who retired lately to speak highly of the service, as they lived here when things were cheap and money could be made; the rupee was worth considerably more than 2*s.*, and it is now value for 1*s.* 9½*d.* They had the advantages of the pension fund, and could retire on nearly twice as much as those entering now have offered to them.

The other medical services have been improved, while the Indian has been steadily degenerating, and living on the good name it formerly obtained. Everything has been cut down to the lowest figure by the authorities, and there is very little prospect of amends being made; but it would not be so bad if we had known what was before us.

Your obedient servant,

India, September, 1875. A BIRD CAUGHT WITH CHAFF.

CARIOUS TEETH.

DR. LARDIER advises, in *L'Union Médicale*, to drop some collodion into carious teeth, after the latter have been cleaned and dried. The liquid collodion exactly fills the cavity of the tooth; the ether evaporates, and narcotises the nervous twigs. By solidifying, the collodion protects the tooth from the contact of the air. Dr. Lardier states that he has thus succeeded in relieving many patients.

Mr. Domville, (Exeter.)—Our correspondent's communication has been received, with the manual to which he refers.

SANITARY CONDITION OF MORTLAKE.

To the Editor of THE LANCET.

SIR,—In your abstract of my report of the Richmond Rural District, you do not mention that it was the report for the year 1874. The natural conclusion on reading the abstract is that the report refers to the present time, and that the condition of things in Mortlake mentioned there still exist. I am pleased to be able to assure you that such is not the case. The outbreak of sickness referred to occurred at the end of 1873 and in January, 1874. Directly the state of matters was brought to the notice of the authority, active remedial measures were adopted, and the result is that Mortlake is now as healthy as any other part of the district, and I believe entirely free from diphtheria. The deaths for the past three quarters have been at the rate of 15·7 per 1000 per annum, so that the heading of the page on which you have printed the abstract is likely to mislead and cause unnecessary alarm.

Yours obediently,

Barnes, Oct. 30th, 1875. J. ADAMS.

SELLING DEGREES OR DIPLOMAS.

OUR readers will be glad to observe that the Minister for the United States has called attention to the systematic fraud which has been perpetrated by persons in this country engaged in selling degrees or diplomas purporting to be conferred by certain American Colleges and Universities. Being satisfied that these distinctions and honours were pretended and spurious, General Schenck made the imposture a subject of correspondence with his Government. Inquiry having been especially made in relation to the Philadelphia University of Medicine and Surgery, and the Livingston University of America, institutions so called, of which there are professed agencies in London and elsewhere, the Governors of Pennsylvania and New Jersey, the States in which these Universities are respectively described as being situated, have forwarded communications to the United States Minister in London, which demonstrate that a fraud is being perpetrated by those engaged in this traffic of degrees and diplomas. We sympathise with the American Minister in his desire that the individuals in question should be exposed and, if possible, punished.

NORTH CAMBS COTTAGE HOSPITAL.

THE letter of the *Rev. Alfred J. Perry* has been received, and shall be published in our next impression.

UNQUALIFIED PRACTICE AND QUALIFIED PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—A medical man, living four miles from this place, has held the appointment of surgeon to a club (of Foresters) for many years; but, unable to do the work latterly (the club having increased, the majority of the members living here, and still further away from his residence), has now a house in this village, with his name on the door, and an unqualified substitute residing therein. He calls the latter his assistant, and takes all responsibility upon himself, notwithstanding the distance, and, as a necessary result, the "assistant" has uncontrolled charge of most of the cases. The "assistant," however, repudiates this title; says he is one of the firm, receives the title of doctor, and is considered as one by the unenlightened public; and if club members are dissatisfied and apply to the surgeon proper, the assistant tells them he is their club doctor; that his "patron" has made over the club to him. They can have the services of their surgeon if the assistant calls him in as a consultant; but if they prefer to send for their surgeon, or should put themselves to the inconvenience of walking to his house, they are asked why they have not gone to the substitute he has provided for them.

Inconvenience occasionally results from this state of things. Certificates to entitle a member to his sick allowance, formerly signed by this young man with his initials placed above the name of the surgeon, are now, by an order of the High Court, not received, and have to be signed in full by the surgeon, who ought to see the patient before doing so. This can be, and is doubtless easily, arranged; for the patron not unfrequently goes away for a time, leaving the "assistant" in entire charge of both practices, the parent and the branch.

You have said in your journal lately that Friendly Societies have the remedy in their own hands; but it not unfrequently happens that these Societies are ruled by a few; and as this person has so far qualified himself for the office of deputy-surgeon by becoming an ordinary (or financial) member of the club, he is enabled to attend all the meetings, and has thus managed to get the support of some of those in office, to the great dissatisfaction of many of the members, who naturally object to the services of a servant, when they ought to have the master, and when there are qualified and competent medical men at hand.

In this unqualified practice (going beyond the area of the club) death certificates *have* been signed by the principal in cases where he has never seen the patient. He now, whenever it can be managed, sees the patient at least once, to legitimise the certificate, or make good the debt—i. e., recoverable. A good many deaths, however, are returned by the registrar as "not certified." This official has a very simple method with certificates that are written out on blank paper, and signed by the unqualified one. He asks the friends if they are satisfied that the patient died of the cause alleged, and if they are satisfied, he is; and the coroner of this district, advanced in years, and paid by salary, and that a small one, declines "as usual," quoting the words of a local paper, to hold inquests, even in a case of death from chloroform where none were present but the surgeon and his unqualified assistant, and this, too, in a case where the friends of the deceased greatly desired it.

I am, yours &c.,

ONE WHOSE QUALIFICATIONS AFFORD NO PROTECTION.

October, 1875.

*** The case described by our correspondent is a very bad one. It is a striking instance of a qualified practitioner abetting unqualified practice. We do not envy the feelings of the practitioner who can lend himself and his name to an arrangement which operates fraudulently towards the public, and very unfairly towards other practitioners. The profession has great reason to be dissatisfied with the Registrar-General for practically accepting certificates from the unqualified. While such apathy is shown by registrars and coroners as to the evidence of causes of death, we shall have unreliable returns and a very demoralising disregard of human life.—ED. L.

THE PERSISTENCE OF SYPHILIS.

SOME physicians exaggerate this persistence, although it is well known that persons who had formerly suffered from lues venerea have reached a ripe old age without having experienced a relapse. Among these pessimist physicians must be placed Dr. Zeissl, of Vienna. *L'Union Médicale* quotes a passage from one of his lectures delivered a short time ago:—"Some people think that when a patient has for a while shown no signs of syphilis he is quite cured; but I can tell you, gentlemen, that when a human being contracts syphilis he will die syphilitic, and at the day of judgment he will"..............We refrain from translating the professor's concluding words.

Female Medical Missionaries.

We understand that female medical missionaries are now labouring very successfully in various parts of India. The Maharajah of Vezianagram has engaged an American lady to open a dispensary at Benares, exclusively for the benefit of native women; while the enlightened Sir Salar Jung has done the same thing in Hyderabad. Altogether the medical ladies appear to have more work on their hands than they can well do. The Hindoos are credited with being much more susceptible to European influences than the less tractable Mahomedan population, who view with equal horror the missionary and the doctor.

Mr. Maurice S. Duke will have seen that we inserted Mr. Palmer's letter last week, which is to the same effect as his own.

A Monstrosity.

To the Editor of The Lancet.

Sir,—A case of malformed fœtus which has lately come under my care presents features so remarkable that I desire to place it before your numerous readers.

I was called to attend a midwifery case a few weeks ago, and on examining the woman per vaginam I failed to diagnose the presentation. Labour rapidly proceeded, and she soon gave birth to the monster a photograph of which I enclose. The general appearance of the face assumes more that of a pig or a dog. On carefully examining it, you will find that it consists chiefly of a leg, the left. The thigh and buttock are perfectly developed; even the folds of the nates are distinctly marked; but the foot is deformed, and the toes are rudimentary. At the upper end of the thigh, and in the normal direction, extends what seems to be the lower and left half of the abdomen, from which anteriorly there protrude some folds of intestine, enclosed by a covering, partly of skin, partly of membrane. At right angles to the abdomen is joined what seems to be the left side of the thorax, containing, presumably, some lung substance; for, strange to say, the *movements of respiration were carried on for fifteen minutes after delivery.* At the angle of junction between the thorax and abdomen is the distorted left arm, bearing a hand with thumb and two fingers; while occupying the position of the right side of the thorax and abdomen is the head, the face looking backwards. The apex of the head is a membranous bag, containing a little fluid, and occupies the position of the right buttock.

The woman soon after gave birth to a second fœtus, which only lived fifteen minutes.

I am not one of those who believe in maternal impressions; but I may say that the mother does not know to this day that she has given birth to anything abnormal, and, wishing to lead her to suppose that I was seeking for information, she has since told me that soon after finding herself in the pregnant state she was frightened by the screams of a pig and a dog, the latter in a rabid condition worrying the pig to death.

I am, Sir, yours truly,
The Poplars, Barnsley, Oct. 23rd, 1875. Joseph Morris, M.D.

Ignotus.—The fact that some African tribes protect themselves from the fatal effects of the bites of serpents by chewing a particular root rests, we believe, principally upon the testimony of Bruce, the traveller. A story is told somewhere of a gentleman, living at Santa Fé, who was accustomed to seize the most venomous serpents, from the poison of whose bite he protected himself by drinking some of the juice of the "*quaco-withy*," and injecting a portion of it into punctures made in the hands, breast, and feet. The name of the plant is said to be derived from the Indian designation of the serpent hawk, which was observed, before attacking the reptiles on which it feeds, to suck the above-mentioned juice.

The Expedition up the Congo River.

We have received the following letter from our correspondent, giving an account of the measures adopted during the late Congo expedition:—

The squadron comprising H.M. ships, *Active, Encounter, Spiteful,* with gunboats *Merlin, Foam,* and *Ariel,* and storeship *Supply,* were engaged in the active operations of the expedition from the 31st of August to the 11th of September. The larger ships proceeded as far as possible up the river, acting as bases of support for the gunboats, steam launches, and smaller craft, which, with landing parties, proceeded daily up the narrow and difficult creeks, attacking and destroying villages and property. One of the best features in the sanitary regulations was the order necessitating all those landed sleeping on board one of the vessels at night, thereby avoiding the danger from fever incurred by sleeping in the bush. Another plan adopted was to give occasional days off to officers and men, to enable them to recruit after, say, thirteen or fourteen hours' heavy work in boats and bush under a hot sea. The lower decks of vessels up the river were only allowed to be wetted once a week, and then only with warm water, and the deck had to be dried with hanging stoves. No river water was allowed to be drunk, distilled water being exclusively used. An extra ration of meat and vegetables was served out in the evening. Four grains of quina were issued daily to all hands. Cholera belts were also issued, and wicker helmets to the marines landed. Occasional extra issues of coffee and chocolate were made, and a small extra allowance of spirit. This latter was very acceptable after the day's work, when men were completely exhausted; the quantity was so small it could not have done harm, and the excellent moral effect, evidenced by the renewed vivacity and altered temper of men wearied by marching through mangrove swamps under a hot sun, or pulling for many hours in an open boat, was very marked. Many other minor sanitary rules were also observed, and they all seemed to have worked for good, for few cases of fever have appeared, although we have now been over three weeks in the river.

The operations having been concluded, much to Commodore Sir W. Hewett's satisfaction, great loss having been inflicted on the enemy as regards property &c., and very small loss being sustained by us, the squadron is in daily expectation of being dispersed. Our total losses were two drowned, one killed, and five wounded (all with slugs); three of the wounds severe, two slight. The armour plates of the launches and open boats saved many from being hit, and the fact of the enemy firing too high was a fortunate circumstance for those landed.

P.S.—Of course the selection of the dry season must be considered when speaking of sanitary measures adopted; this fact, and also the almost unlimited issue of lime-juice, I omitted to mention in the body of this letter.

Life Governorships to Hospitals.

In each of the years 1873 and 1874 an Association at the East-end of London has, by means of a festival or entertainment, succeeded in raising money sufficient to purchase six life governorships to hospitals in the metropolis. The third entertainment for the same purpose has just come off, and is expected to be at least equally productive. Whilst sympathising with the promoters of this movement in their desire to aid hospitals, we cannot altogether withhold concurrence in the objection that it is a somewhat roundabout way of augmenting the means of relieving the sick poor. In Birmingham at the present time hospital philanthropy appears to be taking an opposite direction. In that town preference is now given to the "free system," which, as it is proposed to be carried out there, will probably be found to work much more satisfactorily than the old and objectionable plan of governors' tickets.

What goes through the Post-office.

It is stated in the recently published report of the Postmaster-General that among the articles posted contrary to the regulations of the department, and sent to the returned letter office, were a horned frog alive, a stag beetle alive, white mice alive, snails alive, an owl, a kingfisher, a rat, carving knives and forks, gun-cotton, and cartridges. Gun-cotton seems a particularly nice article to send through the post.

Jumna has a claim, but scarcely one that we should recommend him to take into a County Court.

"Cheap Doctors."

To the Editor of The Lancet.

Sir,—As you still hold, in common with the medical men in this neighbourhood, that it is unbecoming in me to dispense charity to the poor by means of low charges, which charges have had the effect, not of remunerating me, but of taking off my shoulders a vast amount of vexatious and unnecessary work, I bow to your opinion, and therefore from the present time I shall abandon a system that has brought down such an amount of unexpected censure upon me. At the same time by so doing I shall be obliged, I fear, to give gratuitous advice to those I may think worthy of it, which is a course, in my opinion, more likely to be detrimental to the interests of my medical brethren around me than my system of low charging was ever likely to prove.

Before closing this subject, permit me to add a few words in justification of the handbills, which seem to have been the exciting cause of the movement against me. My position was this: either I must have engaged a ninth assistant, and have run the chance of his proving trustworthy, or relinquished my clubs at a very short notice. I chose the latter course, and had handbills printed to save the kind friends who collected the payments for me the trouble of explanations, which, when given verbally, would, when passed from mouth to mouth, have given rise to mistakes, which would most likely have taken months to rectify. They were only intended for private circulation, and not as public advertisements.

You will be doing me a great favour if you will give this letter a place in your next issue, that it may relieve the minds of those of my medical brethren around me who were afraid my system of low charges was doing them an injury.

Yours faithfully,
Nayland, Colchester, Nov. 1st, 1875. H. D. Palmer.

The following is another phase of the system of medicine on cheap terms. It is a handbill. We believe Dr. Griffith is a graduate of St. Andrews:—

> "City of London People's Independent Dispensary (established 1866), 5, Circus-place, Finsbury-circus, E.C. (private door, 101, London-wall, E.C.) Terms of subscription, 1*s.* 6*d.* a week, charged during sickness only, and including the physician's advice; bottle of medicine and assistant's advice, 6*d.* only. Physician's hours, 11 A.M. till 5 P.M.; Monday and Thursday, 11 A.M. till 8 P.M. Physician, S. C. Griffith, Esq., M.D., of 35, Finsbury-square, E.C.; Assistant, Mr. Canning; Junior Assistant, Mr. Edwards; Dispenser, Mr. Williams. Mr. Edwards resides on the premises, and will give medicine and advice at any hour of the day or night......Dr. Griffith can be had at any time for sudden or dangerous cases of illness."

New Schools of Medicine in France.

In addition to the various schools of medicine which it is said the Catholic party are preparing to establish in competition with the present State Faculties, a sixth Government school will soon be erected at Lille, so as to satisfy the wants of the northern districts. There are already five schools in existence, three of which are in full work—Paris, Montpellier, and Nancy,—while the other two are preparing to open—namely, Bordeaux and Lyons. As to the immediate result of this sudden and considerable increase in the number of Faculties, few in Paris, even amongst the most competent, are able to form an opinion. Some expect much good from this radical measure, whilst others lament the change.

Mr. James Thomson, (Clifton.)—The places under the Acts are, we believe, as follows:—Devonport and Plymouth, Portsmouth, Chatham and Sheerness, Woolwich, Aldershot, Shorncliffe, Colchester, Winchester, Dover, Canterbury, Maidstone, Cork, the Curragh, and Windsor.

Life Insurance Medical Fees.

The following is the reply of an Insurance Office to an application for a fee for filling up a certificate:—

"London Life Association, 81, King William-street,
"London, E.C., Oct. 29th, 1875.

"Dear Sir,—This being a mutual Assurance Society, and not a trading Corporation, it requires every person desiring to be admitted to its advantages to furnish evidence that he is in good health, without expense to the Society. If he cannot do this he cannot be admitted.

"Mr. ——, therefore, and not this Society, made application to you for a report, and the form in which that might be conveniently given was supplied to him to save trouble. Your application for a fee should, therefore, be made to him.

"I am, dear Sir, your obedient servant,
"Edw. Docker, Secretary."

A Warm Swimming Bath.

Bath is, we believe, the only town which heretofore has been able to boast of the possession of a public warm swimming bath. This advantage will, we hear, thanks to the enterprise of the conductors of the Thames floating bath moored off Charing-cross pier, now be enjoyed during the winter months by Londoners.

The Flexible Stethoscope.

To the Editor of The Lancet.

Sir,—Like your correspondent, Dr. R. S. Hutchinson, I have had in constant use for nearly forty years a flexible stethoscope, *exactly* that delineated in Arnold and Sons' advertisement as a novelty. I have tested carefully most kinds of stethoscopes, and much prefer the flexible to any other for clearness of sounds and ease both to patient and manipulator in auscultation. In fever cases its superiority is at once obvious. To me, at least, the ear-piece is a decided advantage, having tried to dispense with it. The trumpet end, also, I consider improved by having a thin membrane—a piece of bladder—stretched over it. If I mistake not, this sort of stethoscope was that mostly used by the late Dr. Golding Bird. My stethoscope was presented to me by the late Mr. Shaw, Surgeon, of Attercliffe, in this neighbourhood, uncle to the present practitioner there of that name. Only two or three years ago it required a new tube.—Yours &c.,

November, 1875. J. Balbiernie, M.A., M.D.

Suppression of a Grave Nuisance.

Mr. W. H. Kempster, medical officer of health for Eastern Battersea, lately reported to the District Board of Works the existence of the following nuisance:—

> "On a small plot of ground in Brougham-street, a depôt for lint, tow, and other *débris* from the hospital wards of the metropolis was discovered. These materials were saturated with human blood, pus, and other animal discharges of an offensive character, smelling most abominably, and dangerous to health from the character of the deposit. It was found that the lint was washed, prepared, and sold again; and, still more horrible, the tow was washed and made into ordinary twine in a contiguous railway arch. Considerable difficulty was found in suppressing this disgusting trade, which was at last only effected by putting strong pressure on the officials of the several hospitals to induce them to destroy these matters on their own premises by means of fire, They are now consumed in the furnaces of the respective hospitals instead of being mixed with ashes and other refuse as formerly."

Communications, Letters, &c., have been received from—Prof. Humphry, Cambridge; Dr. George Johnson, London; Dr. Sedgwick, London; Dr. Wiltshire, London; Mr. J. Adams, Barnes; Mr. Keyworth, Birmingham; Dr. Inglis, Cheltenham; Staff Surgeon Mulvany; Mr. J. N. Stone; Mr. West Walker; Mr. Kearney, Much Wenlock; Surgeon J. C. Medical Diary for the ensuing Week.

Monday, Nov. 8.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10½ a.m. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ p.m. each day, and at the same hour.

St. Mark's Hospital.—Operations, 9 a.m. and 2 p.m.

Metropolitan Free Hospital.—Operations, 2 p.m.

Medical Society of London.—8½ p.m. Mr. Jabez Hogg, "On Spinal Concussion." — Messrs. Carr Jackson and Spencer Watson will exhibit a Patient on whom Excision of the Astragalus was performed for Complicated Injury to the Foot and Ankle.

Tuesday, Nov. 9.

Guy's Hospital.—Operations, 1½ p.m., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 p.m.

National Orthopædic Hospital.—Operations, 2 p.m.

West London Hospital.—Operations, 3 p.m.

Royal Medical and Chirurgical Society.—8½ p.m. Dr. Semple, "On Diphtheria and its relations to (so called) Croup."

Wednesday, Nov. 10.

Middlesex Hospital.—Operations, 1 p.m.

St. Mary's Hospital.—Operations, 1¼ p.m.

St. Bartholomew's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

St. Thomas's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

King's College Hospital.—Operations, 2 p.m., and on Saturday at 1½ p.m.

Great Northern Hospital.—Operations, 2 p.m.

University College Hospital.—Operations, 2 p.m., and on Saturday at the same hour.

London Hospital.—Operations, 2 p.m.

Samaritan Free Hospital for Women and Children.—Operations, 2½ p.m.

Hunterian Society.—7½ p.m. Council Meeting.—8 p.m. Mr. J. E. Adams will exhibit a Case of Plastic Operation on the Face for Rodent Ulcer, and will read "Notes on a Case of Iodide of Potassium Poisoning."—Dr. Peacock, "On a Case of Aortic Disease originating in Malformation," and will exhibit Specimens of Malformation as a Cause of Valvular Disease.

Epidemiological Society.—8 p.m. Inaugural Address by the President, Mr. Netten Radcliffe.

Thursday, Nov. 11.

St. George's Hospital.—Operations, 1 p.m.

Royal Orthopædic Hospital.—Operations, 2 p.m.

Central London Ophthalmic Hospital.—Operations, 2 p.m., and on Friday at the same hour.

Friday, Nov. 12.

St. George's Hospital.—Ophthalmic Operations, 1¼ p.m.

Royal South London Ophthalmic Hospital.—Operations, 2 p.m.

Clinical Society of London.—8½ p.m. — Mr. T. Holmes, "On a Case of Ligature of Femoral Artery with Carbolised Catgut."—Mr. W. Haward, "On a Case of Lymphadenoma."—Dr. Murchison, "On a Case of Acute Cancer of the Liver, with Pyrexia, in a Man aged twenty-four"; "On two Fatal Cases of Acute Pyelitis and Nephritis, apparently consequent on Gonorrhœa."

Saturday, Nov. 13.

Royal Free Hospital.—Operations, 2 p.m.

Charing-cross Hospital.—Operations, 2 p.m.

NOTICE.

In consequence of The Lancet being frequently detained by the Post Office when posted for places abroad *more than eight days after* publication, subscribers and others are reminded that such copies can be forwarded only as book packets, and *prepaid* as such.

TERMS FOR ADVERTISING IN THE LANCET.

Clinical Lecture

ON A CASE OF

ECCHYMOSIS OF THE SCROTUM.

Delivered at St. Bartholomew's Hospital,

BY WILLIAM S. SAVORY, F.R.S.,

LECTURER ON SURGERY AND SURGEON TO THE HOSPITAL.

GENTLEMEN,—I bring this case under your notice chiefly because it affords me an opportunity of fixing for a while your attention on an important feature of the affection commonly called Pyæmia, or often now Septicæmia, but which I prefer to speak of more simply, yet more comprehensively, as blood-poisoning: chiefly on account of this, yet also because it illustrates some other very interesting facts in pathology and practice.

G. L——, aged thirty-one, a carman, was admitted into the hospital on the 10th of last December. During the dense fog which then prevailed he missed his way, and drove into the West India Dock. A considerable quantity of blood was extravasated into the scrotum, penis, and perineum. All these parts were black and blue, distended, and tense; but into the cellular tissue of the scrotum, especially on the right side, a very considerable quantity of blood was infiltrated. It was larger than one's two fists put together, and the skin over it was very black and tightly stretched. The state of the integument and its direct relation to the mass of blood beneath, which could be felt to be fluid immediately under it, and in evident continuity with that in the penis and perineum, showed plainly that the blood had escaped into the cellular tissue of the scrotum. There was no evidence of any hæmatocele—of hæmorrhage into the sac of the tunica vaginalis.

Now, when a part has been severely bruised, so as to rupture some of its vessels, the amount of blood which will escape depends on—(1) the vascularity of the part, and (2) the laxity of the structure. Hence hæmorrhage into the eyelids and scrotum is especially apt to be extensive. (3) The idiosyncrasy of the person—his tendency to bleed—the state of his tissues. Every one knows how widely persons differ in this respect. Some people, especially fat women advanced in life, are bruised by a mere touch; nay, sometimes the degenerate vessels will give way without direct violence of any kind. I may mention here a remarkable example of this.

A very fat elderly woman was brought to the admission room of the hospital on account of some sprain or other injury to the back. She was ordered into Stanley ward, and as the porters were carrying her in the sedan chair up two or three steps they gave her a sudden jerk. She started from fear of being upset, but it was quite clear that she was not struck anywhere. Shortly after she had been placed in bed, however, it was noticed with surprise that the poor woman had a pair of very large black eyes. We all were sure that there was nothing of this when she came to the hospital, and she could in no way account for the change. There was no suspicion of any direct violence, and there can be no doubt that some of the vessels of the eyelids had given way from the severe shake. This led, of course, to a careful examination of the heart, the first sound of which was very unsatisfactory; but there was no evidence, in her respiration or elsewhere, of any material embarrassment of the circulation. But what was anticipated happened shortly after. She died suddenly in her bed.

Finally, the extent to which bleeding proceeds is largely influenced by the conditions to which the injured part is subsequently subjected.

Now what was to be done in the case of the carman? Clearly nothing in the way of active interference. We had to rely on rest and time, watching meanwhile to meet any untoward symptoms, should they arise.

What may happen, then, when blood is extravasated into the cellular tissue without breach of surface? The surrounding tissues become stained, and if the effusion be subcutaneous we have the familiar characters of a bruise or ecchymosis. The integuments are discoloured; they present a livid red, or dusky blue tint, over an area which gradually extends and becomes lighter at the margin. The tint, when recent, varies from dark purple to crimson, being, no doubt, chiefly determined by the degree of exposure to the air. Thus blood effused into the conjunctiva even acquires rapidly, as is well known, a bright scarlet hue. Then, as the blood disappears, various shades of violet and olive-brown are intermingled. By and by the part becomes greenish, then at length yellow, and this slowly fades through pale lemon until the skin regains its natural colour.

The most favourable result of an ecchymosis is that the effused blood is absorbed. At first, supposing previous coagulation, the liquid portion or serum disappears with more or less of the colouring matter dissolved in it; then the colouring matter, set free by the disintegration of the cells, is taken up, and finally the fibrine, which previously undergoes a kind of fatty degeneration. It may be a question, however, whether all the fibrine which is formed under these circumstances is absorbed so frequently as it is supposed to be. Certainly sometimes, and perhaps more often than is usually believed, a tough mass of fibrine remains, it may be in layers, which either hardens and contracts into an imperfect form of fibrous tissue or false membrane, or, more rarely, becomes penetrated by earthy salts and calcifies.

In large circumscribed extravasations which have coagulated there is, after a while, especially towards the centre of the clot, sometimes evidence of fatty degeneration. More rarely crystals of hæmatoidin are met with. But it is perhaps in the smaller and more diffuse ecchymoses that the colouring matter of the blood is thus transformed.

Reabsorption is of course the most desirable, and, fortunately, under favourable circumstances, it is the most frequent, result. More frequent in diffused than in circumscribed hæmorrhage; for as blood coagulates in circumscribed effusions the fibrine is deposited at the circumference, and so separates the more fluid portion of the blood from the surrounding healthy vessels.

But everyone knows how blood thus let loose among the textures and excluded from air will sometimes remain for weeks, or even months, without apparently undergoing any material change. Its bulk does not visibly vary, and, when handled, it still gives the impression of being fluid. And when let out under these circumstances, even after a considerable period, it will spontaneously coagulate more or less perfectly. It seems clear, therefore, that while shut in among the tissues coagulation has been delayed. We know, in fact, that the coagulation of the blood is long delayed under these conditions. But again, when blood, so extravasated, is evacuated after a lengthened period, it sometimes still escapes in a fluid form, but now no longer with the power of coagulation under exposure, and having lost the characters of recent blood. It appears as a thick black fluid, like treacle somewhat diluted; and the microscope shows that the cells have, for the most part, broken up. Such collections, remaining for months, have been described as sanguineous tumours, and dignified with the name of Hæmatoma. Now, what previous changes have led to such a state as this? Has the act of coagulation been altogether prevented in blood thus dead, and perhaps putrid? Perhaps so, in some cases; yet here again it has, to say the least, been rendered highly probable, by the facts and elaborate arguments which Morrant Baker has brought forward, that there has been some degree of coagulation and a subsequent breaking down of the clot.

As a rule, no doubt the structural elements of blood thus effused gradually undergo disintegration—as a rule, the exceptions to which are perhaps not so numerous as they may at first sight appear to be. For, under the circumstances in which blood is usually extravasated, it is probable that slight hæmorrhage may recur at intervals for a long time, and this, with the addition of serum continually oozing from the walls of the cavity and simultaneous absorption, may account for the recent characters presented by some of the blood which has thus been long pent up.

Blood effused may become what is called "encysted." This form of expression is an unfortunate one, for the term "encysted" is liable to mislead. The so-called cyst wall is, as Prescott Hewett long ago showed in his admirable paper, nothing more than the outermost layer of the blood-clot, which, being closest to or in actual contact with healthy structures, most speedily and completely undergoes those changes which lead to its organisation and conversion into membrane. The boundaries of the space, however, in which the blood lies at the same time usually become more consolidated and defined, so that indeed sometimes the cyst-wall seems to be formed partly of the peripheral portion of the blood-clot and partly of the circumjacent tissue. The serum which usually constitutes the contents of the so-called cyst varies in tint according to age. The colour, at first deepened by cruorine, gradually disappears, until the fluid may become either pale and clear or only slightly clouded by fat-molecules. Sometimes, however, clots of fibrine or of blood of various hues are found in the cavity; or, again, sometimes the cavity appears as a mere slit, the walls of the cyst being in contact. In this way is usually formed the well-known apoplectic cyst.

Not only may extravasated blood in exceptional instances become organised, acquiring ultimately the characters of fibrous or connective tissue, but it may become vascular. This is particularly well shown, as Prescott Hewett pointed out, in the blood-cysts sometimes found in the cavity of the arachnoid. As he says: "After a certain period the membranes forming these cysts become thoroughly supplied with bloodvessels, which may be seen in countless numbers permeating their whole structure; in severe cases it has been noticed that a minute network of vessels, most beautifully injected, is found at the margin of the new tissue, thus marking the point of union between the original and the false membranes."

Suppuration may occur during the process of disintegration, pus forming around and mingling with the effused blood; and this, next to absorption, is perhaps the most frequent event of extravasation. This process is, of course, preceded and accompanied by inflammation, the signs of which are usually obvious. There is increase of the swelling; more pain, tenderness, heat, and perhaps fever. The skin over it becomes red, and the integument grows thinner, especially at the focus, which is at length perforated.

But above all, and especially for our present purpose, it is important to understand that, in the process which leads to suppuration, a new layer is quickly developed—in fact, a wall of granulation-tissue is formed, which intervenes between the fluid and the surrounding vessels.

Lastly, there may be rapid decomposition of the effused blood; but this, happily, is rare, for it is apt to be followed by poisoning of the system.

Whether there shall be reabsorption, suppuration, or putrefaction depends very much on the degree of damage which the surrounding tissues have sustained. If these can recover, reabsorption may follow; but if these are so injured as to break down and decompose, suppuration or decomposition of the blood must inevitably occur.

It is clear, then, that even for the most favourable issue—absorption—a long time must at least be spent. Cannot this time be shortened? In a word, Why not at once let out the extravasated blood, and so bring to an abrupt close a course which is otherwise so tedious and uncertain? Why not! Because so long as blood is thus shut up in a close cavity, even when not absorbed, it may remain for an almost indefinite period without decomposition, or at all events without such decomposition as may lead to mischief. But when such a cavity is opened and air admitted, active changes begin at once, and then soon follow inflammation and suppuration and great danger of blood-poisoning. Hence surgeons are very reasonably shy of any interference of this sort, and usually prefer to wait, however long, in the absence of inflammation, suppuration, or other evidence of decomposition.

Then, as a rule, to which there must be very few exceptions, you are not to think of opening a cavity into which blood has been recently extravasated.

Probably, however, some of you may be aware that this exceptional practice is adopted in "certain circles" as a time-honoured custom; though here, no doubt, more in obedience to the exigencies of the hour than upon any calculation of the result. Prize-fighters are very apt to get black eyes; and, as the swelling rapidly increases, the lids become closed. Now, as the odds must be heavy against a blind champion, his friends and patrons secure for him temporary vision by puncturing the bruised eyelid, and then forcibly squeezing out its contents. That such a practice must occasionally lead to graver mischief I suppose there can be no doubt, although I should imagine that if such a proceeding be adopted at all it might be done with far less hazard immediately after the escape, while the blood is quite fresh, and therefore would take longer time to decompose.

But, short of this rough-and-ready method, can the surgeon do absolutely nothing for an ecchymosis but wait and watch? Yes; he may, in the first instance, do something to check further effusion by the adoption of means calculated, under the circumstances, to restrain hæmorrhage—by rest, position, judicious pressure, and the cautious application of cold. The old popular plan of at once pressing the handle of a spoon or some other convenient instrument on the part of a child's head which has been struck is a remarkably good one. The pressure not only tends to restrain further hæmorrhage, but it diffuses the blood which has already escaped into the surrounding tissue, and so perhaps hastens its subsequent absorption. Then, when the chance of further hæmorrhage has passed by, there are numerous applications one or other of which has found favour at different hands—lotions of vinegar or of acetate of lead or of arnica, for examples. The tincture of arnica, more or less diluted, is an immense favourite with some. It certainly has, in some instances, a remarkable power of allaying the severe pain sometimes associated with a recent bruise, and it is believed to promote absorption. But there is this objection to its use. The tincture of arnica, even when much diluted, is very apt in some persons to produce irritation and inflammation of the skin. After its application for a day or two, erythema or eczema is prone to appear, and hence annoyance and distress; so when you use it be on the look out for this. Then, further on in the case, various stimulating liniments and iodine may be had recourse to, or another very popular remedy with pugilists—a poultice made of the scraped root of the black briony; there is, however, the same objection to this as to arnica—that it is apt to irritate and inflame the skin. When the amount of blood which has escaped is not very considerable, and there is much stiffness and tenderness of the injured parts, warmth and moisture are often very grateful in the form of water-dressing, fomentation, or even poultice. But the latter application is usually reserved for the occurrence of inflammation and suppuration, when, in spite of the prejudice with which many regard it, it often gives, I think, more relief than anything else.

To return to our case. The man lay at rest in bed, therefore, for about three weeks, in which time the blood disappeared from the penis and perineum, and almost the whole of it from the left side of the scrotum; but there was little or no reduction of the right side. At the end of this time there was here not only no promise of absorption, but there were signs of commencing decomposition; a blush appeared on the surface, and the integuments became infiltrated; there were heat and some pain. So, not without deliberation, I concluded that by evacuation of the blood I should not only save time, but, what was far more important, lessen the ultimate risk; for it seemed no longer possible that decomposition of the blood could be averted.

Yet I confess I did not decide on this measure without grave apprehension. Let me explain. I feared that the rapid decomposition which would follow the admission of air to the cavity would lead to blood-poisoning. But why should this occur? Almost every day we see putrid fluids shut up, even under heavy pressure, in cavities among the tissues, and yet no poisoning of the blood supervenes. Why not? Here one might suppose are the very conditions for the production of pyæmia: a putrid fluid—animal matter in a state of active decomposition kept in constant contact, and this too under heavy pressure, with a raw surface. Many, indeed, write and talk as if such conditions were the only ones needed to induce pyæmia. They ignore the fact, which is nevertheless so familiar, that these conditions are continually present without the occurrence of pyæmia. I submit that the explanation of this is to be found in the fact that these cavities thus filled are bounded everywhere by a layer of new structure which is, or has the characters of, granulation tissue; and that this limitary membrane, when sound and unbroken, resists the passage of such fluids through its substance into the blood. They cannot penetrate it, or, at all events, they do not pass through it in sufficient quantity or in such a state as to poison the blood. This, observe, is not a matter of mere theory. Actual experiment, in the hands of Billroth and others, has shown that granulation tissue, when healthy, has this power of resistance; and clinical observation, when directed to this question, leads to the conviction that when such tissue is deficient or unhealthy, or presents accidental breaches, decomposing fluids bathing wounds find an entrance to the blood. Further than this, at present, we cannot go. We know nothing of detail concerning the relation in which granulations stand to the act of absorption. But this great fact—for I believe it to be one—seems for the present almost enough. We may, however, bear in mind some of the facts relative to the influence of animal membranes on the act of absorption. The transmission of fluids through membranes is not the simple process it was formerly supposed to be. Not only is it much modified by the nature and surface of the tissue, but also by the character and composition of the fluid. It is now well known that the constituents of a fluid, apparently uniform, may be thus separated by a membrane through which one can and the other cannot pass; and that in this there is a means of analysis more subtle than chemistry can command.

Now this limitary membrane of granulation tissue or allied structure is found only under certain conditions. We are familiar with it as the superficial layer of healthy wounds, and we know that the wall of an ordinary abscess is similarly constructed. But the growth of such a structure requires time, and is the result of processes which need at least a certain measure of local health; and the formation of healthy pus is an associated act. But when extravasated blood collects in a cavity no such bounding tissue can of course at first exist. Time at least must intervene, and, at any rate for a while, such collections of blood can be circumscribed only by the tissues amidst which they lie. Whether such a wall shall be afterwards built depends on the kind of action which is set up in the surrounding tissues. The signs of this are usually those of inflammation and suppuration, such as we commonly recognise in the formation of an abscess.

In the case before us I saw no evidence that such a state of the part had been brought about, and therefore I was apprehensive that, when this cavity was laid open, any putrid matter that might form would gain an entrance to the blood. "Then," you will say, "why not have waited longer? Why did you interfere with such a prospect of doing mischief? Couldn't you have left it alone?" My answer is that it appeared to me to be a choice only of evils. I apprehended danger from exposure of the cavity; but I anticipated danger, too, from the decomposition of the blood as it was, and I hoped that by evacuating the fluid as completely as possible, and afterwards freely washing out the cavity with an antiseptic fluid, my patient might escape altogether from the danger.

Well, the cavity was laid open by a free incision, a large quantity of blood, changed into a thick black fluid like treacle, with broken clots, was evacuated, and the cavity was at once washed out thoroughly but gently with water and Condy's fluid.

And, now, mark what followed. This was done on the 2nd of January, and for two days there was no observation of importance; but on the 5th the report says: He has had two or three rigors, and has been sick. Complains of severe frontal headache and thirst; no appetite; skin moderately moist. Temperature 102·4°; pulse 106. On the following day (the 6th) the temperature was 102°; pulse 95. Headache and aspect better. He complains of slight tenderness along the left spermatic cord and above the pubes.—7th: Temperature 101·4°; pulse 96. Slight headache continues. In the afternoon it became severe, and there was recurrence of rigors and sickness, followed by profuse perspiration.—8th: Temperature 100·4°; pulse 88; and he was altogether much less distressed.—9th: Temperature normal; pulse 68. Declares that he feels well. On washing out the cavity in the scrotum there was for the first time an escape of pus.—10th: Again slight headache. Complains of severe pain in the left testis, and upward along the cord.—12th: Temperature 104°; pulse 100. Rigors, vomiting, and severe headache; much pain; and now swelling of the left cord.—13th: Temperature 104°; pulse 96.—14th: Temperature 100·3°; pulse 80.—15th: Temperature 101·2°; pulse 80.—16th: Temperature 100·4°; pulse 80. Acute tenderness along the left cord; and now a sense of fluctuation there.—19th: Temperature 100°; pulse 80. Since the last report the pain along the left cord has been severe, and fluctuation is now distinct. A free incision was made, and a quantity of laudable pus let out. No rigor or other disturbance followed. Mark this.—20th: Temperature normal; pulse 80. Altogether better.—21st: Feels quite well. Appetite returning. From this date he rapidly recovered, and soon left the hospital.

Now, really, it might almost seem as if such a case as this were given for our learning. In striking contrast to the collection of blood on one side we have on the other a collection of pus—an extravasation and an abscess. On the one hand fluid liable to decompose lies in contact with naked tissue, and when it does decompose the poison is absorbed into the blood. On the other hand, fluid liable to decompose is separated from the surrounding tissues by a new wall, which has been previously built up, so when it decomposes there is no absorption and no blood-poisoning, for I need hardly tell you that pus when exposed to the air will decompose. I said it was healthy pus—not putrid—when let out. But, of course, and especially in such a cavity as that which in this case remained, some pus must be retained, and must under these circumstances rapidly change. And we know very well, as I have already said, and will repeat once more, putrid pus and other fluids are frequently seen in cavities and on wounds without the signs of poisoning of the blood. For my own part, I confess I cannot account for the contrast without having recourse to the wall of the abscess.

The great lesson taught by this case was never more needful than now, when, as during late years, in researches on blood-poisoning, attention has been called from the study of causes operating within, and has been directed wholly to those operating from without. Was this a case of "hospitalism," think you? Do you imagine that the determining cause of the mischief was in the ward, or the bed, or anywhere but in the condition of the injured part? The air with its germs was equally admitted to both sides—to the ecchymosis and to the abscess; and will not pus decompose as well as blood? Whence, then, the difference, oftentimes as great as that between life and death, which in this striking instance is forced upon the attention of everyone?

STEALING AS A SYMPTOM OF GENERAL PARALYSIS.

BY HENRY MAUDSLEY, M.D., F.R.C.P.,
PROFESSOR OF MEDICAL JURISPRUDENCE IN UNIVERSITY COLLEGE, LONDON.

THERE can be no doubt that no little popular suspicion meets the allegation of insanity when it is made in defence of a person who is on his trial for the perpetration of some crime. Nor can it be said that the suspicion is entirely unwarranted by the use, or misuse, which is sometimes made of this mode of defence. It is too often had resort to by lawyers merely as a last resource, when all other means of defence fail, and when there is no real justification for setting it up. Moreover, there is a popular feeling, which judges commonly share, that it does not require any special knowledge in order to settle whether a man is mad or not, and that those who have made a special study of the subject of insanity are sure to discover symptoms of the disease wherever they look earnestly for it. Of a great many cases of insanity it is quite true that the public can judge almost as well as the doctors; the wayfaring man, though a fool, is not likely to make a mistake concerning them. In respect of a certain proportion of cases it may be admitted that doubts and differences of opinion are justified; belonging to the borderland between insanity and crime, they may be reckoned insane or criminal according to the standpoint from which they are looked at. But there are not a few cases in which the symptoms, though positive and definite, are not recognised and rightly interpreted by anyone who has not, by close observation of the manifold varieties of mental derangement and practical experience in dealing with them, acquired an intimate knowledge of what they betoken. If he describes them to the lawyers or to the public, and expounds their meaning, he is thought to be making much ado about nothing by detecting evidence of madness in innocent trifles, if he is not met outright with ridicule and scorn. It is not difficult for ignorance, appealing to the prejudices of ignorance, to raise an empty laugh against a truth of which there is not the least comprehension.

Among these cases of mental derangement which are apt to be overlooked or misunderstood are cases of general paralysis of the insane in their early stages. No form of insanity has been more studied or is better known than this. Its symptoms are, though slight at first, definite and characteristic from the beginning; its course is wonderfully uniform; and its mode of termination and the time thereof may be predicted with considerable accuracy. Moreover, unlike other forms of insanity, it presents motor as well as mental symptoms from the commencement; wherefore it might be said to exact attention and to claim recognition from those who have not made a study of mental diseases. Nevertheless, the most grievous mistakes are often made concerning this disease in its early stages, not by lawyers and juries only, but by medical practitioners; and so it happens that patients struck with fatal organic disease of the brain, declaring itself by symptoms which could hardly speak more plainly than they do, are tried, sentenced, and punished as common-place criminals.

It is well known to those who know anything of insanity that a propensity to steal is a striking symptom in the early stages of some cases of general paralysis. A person whose character has been irreproachable in all the relations of life, and whom no one would ever have suspected of an inclination to break the eighth commandment, after surprising and distressing his friends by irregularities of conduct at variance with the respectable uniformity of his former life, seems to lose the consciousness of the difference between what is his and what belongs to another, and in the quietest way, as if he were doing nothing extraordinary, appropriates what strikes his fancy at the moment, and what he has, perhaps, no use for, and, when he has got it, makes no use of. The stealing is often done in a stupid way, without any adequate motive or without the outlook of any gain thereby, apparently in obedience to an impulse to possess springing up in a mind in which the sense of right and wrong has been weakened or extinguished. In some cases the patient makes no attempt at concealment; but in other cases there lingers a remnant of the sense of right and wrong which, too feeble to contend with the stealing impulse, leads to bungling attempts to hide the petty larceny.

In the *Journal of Mental Science* for January, 1873, Dr. Wilkie Burman relates the particulars of six well-marked cases of general paralysis admitted into the West Riding Asylum at Wakefield, *after having undergone the whole or the greater part of their punishment in gaol* for larceny; and, in regard to these cases, he expresses his conviction that the disease might easily have been diagnosed at the time of imprisonment, without any very prolonged examination, "by any medical man who had even the most rudimentary knowledge of the symptoms of general paralysis." Indeed, in one of these cases the disease was actually recognised by a barrister who was present in court when the man was tried, and yet this unfortunate man remained in gaol for five months before being sent to the asylum; he underwent the punishment of a criminal for five months after a hopeless disease of the brain had begun to make its fatal progress. Another person suffering from general paralysis was sentenced to six months' imprisonment for stealing two wheelbarrows and twelve hundredweight of coals in open daylight, without any attempt at concealment, and without being in want of them, as he was in comfortable circumstances. He was kept in prison for four months, having been in the hospital occasionally during that time on account, it was said, of "some slight bodily ailment." However, this slight bodily ailment did not fail eventually to culminate in such violence and excitement as necessitated the patient being restrained by a strait-jacket and confined in a padded room during the last three weeks of his imprisonment, after which he was sent to the asylum, where his disease made rapid progress. Another person was sent to gaol for twelve months for stealing some wine-glasses from an hotel. A fortnight after his discharge from prison he was admitted into the asylum in an advanced state of general paralysis, and he died about three weeks after his admission. These cases presented on admission into the asylum the usual exalted ideas of general paralysis, as well as the distinctive bodily symptoms. They and the other three cases which Dr. Burman mentions were admitted into the West Riding Asylum within a comparatively short time, and had presumably undergone their punishment in the gaol of the West Riding at Wakefield.

I will now give the particulars of a case that occurred in my practice, which illustrates the same lesson and excites the same painful reflections as Dr. Burman's cases. H. J. P—— was brought to see me in the early part of September, 1874. He had recently failed in his business, and his changed character and peculiar manner had for some time occasioned anxiety to his friends. It was a question of the propriety of endeavouring to get him admitted into Bethlehem Hospital. When I saw him, his symptoms were such as led me to think that he was struck with general paralysis, and to say that he would probably not live two years. There was a slowness of conception, with a certain vacancy of look, which gave the appearance of some degree of stupidity; there was also exhibited at times a slight uncertainty, hardly amounting to tremulousness, in the action of the muscles around the mouth; and there was a remarkable incapacity to realise that there was anything the matter with him, or that his failure in business at all affected his future prospects. He seemed to think that it would be easy for him to go on as before, and that he would have no difficulty in getting advances of stores from the houses which had suffered by his failure. At the same time, when it was pointed out to him how unlikely this was, he assented in a placid and indifferent way, but evidently without sincerely realising what he assented to or being convinced by what was said. At the urgent desire of his wife, who could not be persuaded how seriously ill he was, and who was naturally unwilling to send him to an asylum, he was allowed to go with her to the seaside, she having been warned to never lose sight of him. While resting there he seemed to improve; but one day, having obtained some money from her, under I know not what pretext, he disappeared. The next thing that was heard of him was that he was in custody at Doncaster for stealing a watch. He had gone directly from his wife and taken the mail train to the north on the night of Sept. 24th, 1874, and at Peterborough had got into a carriage in which was another passenger. This person went to sleep, and when he awoke his gold watch and his fellow-passenger were gone. When the train was searched, H. J. P—— was found in another carriage, and the stolen watch was underneath the seat on which he was sitting. When taken to the police-office, he remarked to the constable, in reference to the handcuffs which had been put on him: "You should not have put these things on me. Oh, what a disgrace!" Knowing the condition of disease in which he was, I was not greatly surprised when told by his friends what he had done, and at their request I willingly gave them a certificate that he was in my opinion a person of unsound mind, being in the first stage of general paralysis, and that arrangements had been in contemplation for placing him in an asylum. However, this view of his state did not commend itself to the surgeon of Wakefield Gaol, who could find nothing the matter with him, and had no hesitation in declaring him to be quite sound. Feeling that, under these circumstances, a great injustice was likely to be done to a man who was afflicted with hopeless organic disease of the brain, I wrote to Dr. Crichton Browne, the well-known superintendent of the West Riding Asylum, begging him kindly to examine the man, and, if he found him really afflicted, to do what he could to help him. Dr. Browne readily consented to do so, and, having carefully examined him, came to the same conclusion as I had done, that he was labouring under general paralysis and was not responsible for his actions. Moreover, Dr. Browne was so good as to attend at the man's trial and to give decisive evidence to that effect. Dr. Watts, who had been his ordinary medical attendant in London, was also present at the trial, and gave similar evidence. But it was all in vain. Dr. Wood, the surgeon of the gaol, stated emphatically that he had watched the prisoner carefully for a month, and that he was "sound in body and mind," and the evidence in his favour was received with open incredulity. "I shall not easily forget," Dr. Browne wrote to me, "the smiles of incredulity which pervaded the Doncaster Court-house, from the Recorder downwards, when I described the inequality of the pupils, slight tremor of the tongue, and other *little* symptoms which enabled me to recognise the justice of your diagnosis of general paralysis. I shall not easily forget the derision with which my prediction that the robust, healthy-looking man standing at the dock would not live above eighteen months was received on all hands. The Recorder, taking into consideration the good character which the prisoner had previously borne, sentenced him to two months' imprisonment with hard labour. The poor man thus got the benefit of his previous good character, though he did not get the benefit of the disease which had produced the sad change in his character.

His friends very properly refused to let the matter remain so, and at once made such representations to the proper quarter, supported by affidavits, as led in a short time to the remission of the sentence. A few days after his discharge, on November 27th, I saw H. J. P—— again, and questioned him about the theft, and the motives of it, and as to where he was going by the train. His account was that he thought he would go to Scotland, though he could give no satisfactory reason why he should go there, and would stop at York on the way, in order to see the cathedral; that the idea of taking the watch came into his mind when he saw his fellow-passenger asleep; and that, having taken it, he got out of the carriage, and made his way to another carriage. He was quite insensible to any feeling of shame on account of what he had done, and seemed unable to realise its criminal nature; nor did he evince any sense of disgrace on account of having been in prison, talking of it in fact as freely and unconcernedly as he might have done of a friend's house in which he had been staying for his health's sake. I recommended that he should be taken to Dr. Watts for the purpose of obtaining a certificate of his insanity, agreeing to sign the second certificate myself, and that he should be sent to an asylum; enjoining upon his friends that he should meanwhile be closely watched, as it seemed certain that he would do something extraordinary if he were not under control. Divided family counsels prevented his being put immediately under restraint, and the next news which I had of him was contained in the following paragraph which appeared in the newspapers :—

"*Extraordinary Capture of a Thief.*—Soon after midnight on Thursday, when the mail train for London had passed the Tuxford station, a man covered with blood went to the signalman's box and stated that he had fallen from one of their carriages. His face, head, and hands were very badly cut and bruised, but the railway official had his suspicions aroused and telegraphed to Retford, the next station, for the train to be examined on its arrival there. In a minute or two he received directions, in answer to his telegram, to detain the man, as a robbery had been committed. The man, not knowing that the officials had telegraphed to Retford, asked that he might be sent back to London to his friends by the next train, as his injuries were so severe that he did not feel able to continue his journey to Manchester, for which place he had taken a ticket at King's-cross station. A doctor was sent for, and, after he had dressed his wounds, Sergeant Hallam, of the Notts police, stepped in and apprehended him. On searching him a false beard and moustache were found in one of his pockets, and in another a dagger nine inches long—a most formidable weapon, as sharp as a razor. Two watches were found upon him. It appears that the prisoner had been riding in the same compartment with Mr. Robinson, a Manchester horse-dealer, and one other person. All save the prisoner went to sleep after leaving Peterborough, and did not wake again until they were aroused at Retford to find their companion, the prisoner, gone, and one of their watches also. It is supposed that the prisoner, after stealing the watch from one of the sleeping travellers, left the compartment, and tried to get into another. As the mail was running along at the rate of sixty miles an hour, he, failing to find a compartment which he might enter unobserved, either jumped off or fell from the train. He is a clean-shaved, thick-set, powerful man, and has given the name of Henry James Price. He is now detained in the Retford Police-station, and will be brought up to-day."

Here was a nearly exact repetition of his former performance. He had been again going to the north without any apparent reason, and on his way had again stolen the watch of a sleeping passenger, but this time he had evidently gone with evil design, else why should he have provided himself with the false beard and moustache, and the formidable dagger? The result of the adventure was that he was on Dec. 7th committed to the county gaol at Nottingham to take his trial, but he had not been there long before incontestable symptoms of insanity manifested themselves. Thereupon he was removed, on Jan. 14th, 1875, to the county asylum. On Feb. 24th he had three severe fits of an epileptic character; similar fits recurred from time to time during the following month; his mind became more and more enfeebled, and his bodily strength declined; furious mania supervened, and he died from exhaustion on August 31st, after being raving mad for eight weeks.

Comment upon this case is unnecessary. It will be enough to express regret that the unhappy sufferer should not have found in medical help the protection and treatment which his sad and hopeless disease demanded, and a conviction that the time has come when it is the duty of medical corporations to exact some knowledge of mental diseases from those upon whom they confer their licences.

Hanover-square, W.

A USEFUL METHOD OF EXCISION OF THE ELBOW-JOINT.

By C. F. MAUNDER, F.R.C.S.,
SURGEON TO THE LONDON HOSPITAL.

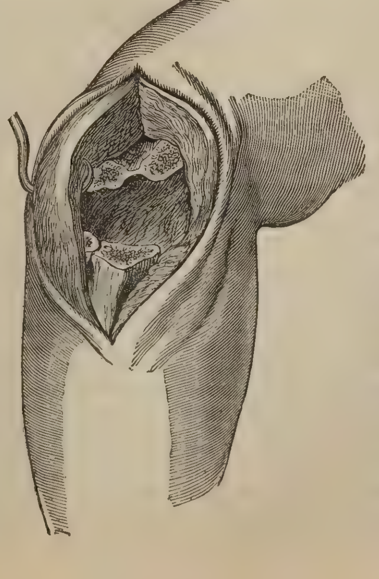
It is scarcely necessary to suggest that, in performing an operation, the local consequences should be kept prominently in view. To know the result of an operation some years subsequent to its performance is the best way of appreciating its merits, and must be my excuse for publishing extracts from a letter which I have just received from New Zealand, from a gentleman whose right elbow-joint I excised about six years ago.

"*From J. N——, Hereford street, Christchurch, New Zealand, August 5th,* 1875.

"Dear Maunder,—You will be glad to learn that my arm has won the champion billiard cue in the late match here; also that I took second honours in quoits. I send you a paper per post.......I have left a clause in my small will that my arm shall be preserved and sent to you for examination and dissection after my death. I believe it to be the finest arm in the world without a joint.—Yours truly, J. N."

The case was one of very severe compound comminuted fracture of the ends of the bones forming the right elbow-joint, and to which I was called by Dr. Floyer, of Bishopsgate. I performed excision on a method which I suggested to the profession as a *certain* means of securing active extension by the triceps—a desideratum hitherto only rarely, and then accidentally, attained. Briefly put, my object is arrived at by avoiding all transverse section of the soft parts lying between the point of the olecranon and the external condyle of the humerus. In this way the continuity of muscular and aponeurotic structures passing from the arm to the forearm is not destroyed.

Fig. 1.



I have exhibited, from time to time,

at meetings of societies, patients submitted to operation by this method of mine,* and all who saw them were surprised by the amount of the power of extension which was thus secured. Mr. Steele, of the Bristol Infirmary, has both practised and published his approval of the method.

Fig. 1 shows a left arm immediately after the performance of the operation; the hook sustaining the structures which are to be carefully preserved.

FIG. 2.

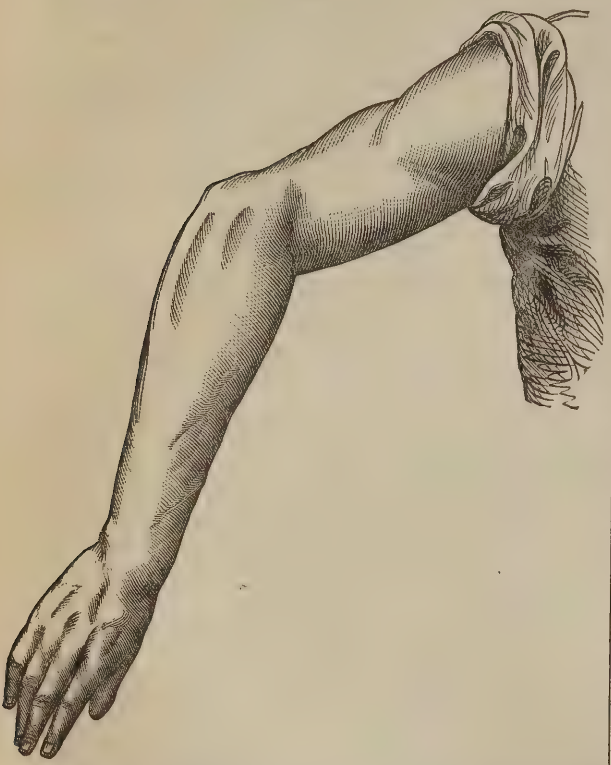


Fig. 2 is a sketch of the arm of J. N——, taken three years ago, and three years subsequent to operation. The forearm is in the position of active extension by the triceps. He could then play billiards, quoits, and use "the gloves" with facility.

Queen Anne-street, W.

ON

FIFTY CASES OF HÆMOPTYSIS TREATED WITH ERGOT.

By JAMES M. WILLIAMSON, M.D. EDIN.,

RESIDENT MEDICAL OFFICER ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR, ISLE OF WIGHT.

ABOUT eighteen months ago, after reading the papers written on the subject by Dr. Anstie in the *Practitioner*, I commenced making a fair trial of the value of ergot in the treatment of hæmoptysis. The success which followed its administration was so encouraging that I gave the drug in every case of hæmoptysis which I was called upon to treat, and I now propose to state briefly the results of its use in fifty cases.

The fifty patients were suffering from phthisis in different stages, and the amount of the hæmorrhage varied from abundant bright streaks on the sputa to the expectoration of several ounces of blood. As the cases all occurred in hospital practice, very little time was lost between the advent of the hæmoptysis and the exhibition of the remedy. The ergot was invariably given by the mouth and in the form of the liquid extract. Much has been said about the success of the subcutaneous injection of ergotin and its superiority to this plan, but since there was no difficulty in any of the cases in administering a draught, and as the drug acted in most instances with a promptitude which was sufficiently satisfactory, the hypodermic method was not employed. Forty-minim doses of the liquid extract may be given twice within the first hour, and, guided by the results, at least every two hours afterwards, the dose being diminished and given less frequently as the hæmorrhage subsides. I have never observed any disagreeable effect follow even upon the administration of large quantities within short periods, but, as a general rule, if four or five full doses make no distinct impression upon the hæmorrhage, the remedy should be abandoned for another. Care should be taken to use a fresh and sound preparation of the ergot.

Out of the 50 cases, the drug rapidly checked all bleeding in 44 instances. Of these 16 were women and 28 men, and in at least one-fourth of the number the hæmoptysis merited the term profuse. In 40 of the 44 cases it was the first and only remedy given; in 2 others it was successful after a mixture containing gallic acid, alum, and dilute sulphuric acid failed; in another it was effectual after acetate of lead with opium proved useless; while in the remaining instance it repressed the bleeding after both of these plans were unavailing. The ergot was ineffectual in 6 cases, and of these it may be well to give some particulars. Case 1 was that of a middle-aged widow, who had had several violent hæmorrhages. On this occasion it was very copious, and repeated doses of ergot, given in rapid succession, produced no perceptible abatement; gallic acid was then substituted, but just as it was making a decided impression it gave rise to such griping pains in the abdomen that it had to be given up; ergot was resumed, and the hæmorrhage rapidly ceased. Case 2 was that of a young man in whom the hæmoptysis was moderate; it was unaffected by ergot, but yielded to gallic acid. It is only right to add that in this case there was some doubt as to the goodness of the sample of ergot used. Cases 3 and 4 were two examples of a slight, but very chronic and obstinate hæmoptysis, in which the sputa had a uniform pink tinge. In one of the men, gallic acid succeeded after ergot proved a failure; in the other, gallic acid, ergot, acetate of lead with opium, perchloride of iron, ammonio-sulphate of iron, the mineral acids, and oil of turpentine, were all successively tried without avail. Case 5 was that of an unmarried woman, aged twenty-five. She had had many previous attacks. Ergot proved ineffectual, and was replaced with success by acetate of lead and opium. Case 6 was that of an unmarried woman, aged twenty-three, who had also had frequent previous hæmorrhages. On this occasion the bleeding was profuse, and resisted both ergot and gallic acid; oil of turpentine eventually subdued it.

The cases in which ergot failed have been stated somewhat fully, partly to show that, in at all events three of the number, it shared the failure in common with gallic acid, the remedy which is probably most frequently employed in the treatment of hæmoptysis. Over gallic acid ergot has the distinct advantages of never causing griping or constipation, and more especially of not interfering with a liberal use of milk. The large proportion—equivalent to 88 per cent.—of the cases in which ergot succeeded, not only testifies to its great value and claims for it our confidence, but also strongly justifies the recommendation that it should be the first drug tried in all cases of hæmoptysis.

Ventnor, I.W.

CASE OF

COMPOUND FRACTURE OF THE PATELLA.

By ARTHUR B. EWEN, M.R.C.S., &c.

THE case of Wound of the Knee-joint treated Antiseptically brought before the Clinical Society by Mr. Pick, and reported in THE LANCET of Oct. 16th, reminds me of a somewhat similar case in my own practice, treated on a different principle. I am not about to dispute the value of the antiseptic mode of treatment; I would merely urge that its great superiority over other and simpler methods is, as yet, not proven. Certainly, as far as the practice of surgery in country districts is concerned, where we have the immense advantage of a constant supply of pure air in our favour, we can challenge comparison with all the recorded results of antiseptic treatment. The treatment by means of fresh air and cleanliness will always commend itself to the surgeon on account of its extreme simplicity, until the results of the more complicated and troublesome system are shown by the most unequivocal statistics to possess the decided superiority claimed for it by its advocates.

---

* Maunder's Operative Surgery, second edition, p. 120.

On Aug. 27th, 1866, Jane B——, aged sixty-four, the wife of an agricultural labourer, while feeding a threshing machine, slipped from the stage and fell into the drum, sustaining severe injuries of the right arm and left knee-joint. She was a healthy, active woman, slightly built, and of spare habit, had had a large family, and was accustomed to field work. On examination I found the forearm and elbow-joint crushed and lacerated so extensively that it was necessary to amputate the arm at the upper third; this I did under chloroform, and then, on examination of the knee-joint, I found severe bruising of the integuments, two extensive lacerations into the joint, and the patella divided into three larger and several very small fragments. I removed five or six small loose pieces of bone from the wound. At first I thought, considering the severity of the damage to the joint, that the best plan to adopt would be to amputate at once; but I feared that, as she had lost so much blood before my arrival—an hour after the accident,—and as she had just undergone the amputation of the arm, I should most likely kill her outright if I removed the leg. I therefore decided to put the leg on a straight splint, and give her a chance of recovery with an anchylosed joint. All the loose fragments of bone and one or two pieces of straw which had got into the wound being removed, I brought the edges together with two silk sutures, and covered the knee with lint saturated with cold water, which dressing I directed to be frequently changed. Twelve hours after the accident she had a pulse of 120, and there was considerable effusion into the joint. The constitutional disturbance gradually and quietly subsided. There was a moderate discharge of healthy pus from the wounds; no burrowing of matter. A small portion of integument, two inches long and half an inch wide, from the upper part of the wound, which extended across the front of the joint, sloughed away, having been severely bruised at the time of the accident. This somewhat delayed the healing process. After the first fortnight she gained strength rapidly, and five weeks after the accident the wounds were healed and all discharge had ceased. On Nov. 10th, seventy-five days after the accident, the patient walked up to my house, a distance of three miles, and expressed herself as being delighted with the very fairly useful limb she now possessed.

One great element in her rapid recovery was the beautiful autumnal weather, which enabled her to enjoy the benefit of constant fresh air. She had her cottage door, which was just opposite her bed, open from sunrise to sunset. She was also of a very cheerful disposition, and from the first seemed to have made up her mind that she should get well. She lived four years after the accident, and died in 1871 of cancer of the breast.

Long Sutton.

NOTES OF FIVE CASES OF ARROW-WOUNDS (RECEIVED IN THE SOUTH SEA ISLANDS), TWO FOLLOWED BY TETANUS AND DEATH.

By SURGEON ALFRED CORRIE, R.N.

(*Concluded from* p. 660.)

CASE 3.—Thomas S——, aged thirty, cook. This man, when on shore (August 12th, 1875) at Santa Cruz Island, received a wound (punctured) of the right side, over the crest of the ilium, not very deep. The arrow was at once removed; the wound, some fifteen minutes after the accident, was sucked and enlarged, and nitrate of silver applied freely. He felt a little giddy and sick at the time. A stimulant was given in the shape of some brandy and water.

Aug. 13th.—Slept a little; rather restless during the night. Pain and tenderness around the wound, extending down the thigh; slight headache; tongue moist and clean; no chills; bowels irregular. Temperature 99°; pulse 80. Ordered cathartic mixture, an ounce and a half; water-dressing to wound.—8 P.M.: Taken food fairly; less pain about wound; still a slight headache; bowels confined. Temperature 99°; pulse 88.

14th.—Slept well during the night. Less pain about the wound; no sicknesss or headache; bowels confined. Water-dressing to wound; cathartic mixture, two ounces. Temperature 98·4°; pulse 80.—8 P.M.: Felt a little sick this morning. Bowels have been opened freely; felt better after it. Is taking food well; wound less painful and looking healthy. Temperature 98·6°; pulse 80.

15th.—Passed a good night. Wound progressing favourably; but little pain or tenderness about it now. Temperature 99·2°; pulse 80.

20th.—For the last five days the patient has been going on well; wound looking very healthy and healing fast. He takes food well; bowels regular. Temperature generally normal; pulse between 75 and 80.

25th.—Wound not quite healed yet, but going on well; patient does not complain of anything, and appears in excellent health. Continue water-dressing.

29th.—The wound having healed without one bad symptom, and the patient appearing in robust health, he was discharged to duty the seventeenth day after the accident. He is at present (Sept. 3rd) working about the ship and going on well.

CASE 4.—Allen J——, aged twenty-seven, seaman. This man received (August 12th, 1875) at the Island of Santa Cruz, a punctured wound, about two inches above the pubis, from an arrow supposed to be poisoned with some animal poison. The arrow was immediately pulled out. It went in about half an inch. Wound sucked fifteen minutes after the accident, enlarged, thoroughly examined, and nitrate of silver applied. Complained of nothing in particular at the time of the accident.

13th.—Slept fairly; felt pain during the night at lower part of the abdomen; no sickness, headache, or chills; tongue a little coated; bowels regular; water-dressing applied to wound. Temperature 98·4°; pulse 66.—8 P.M.: Felt during the day wandering pains all over the abdomen, extending down both thighs; enlargement of glands in groins; had a feeling of sickness during the day, but has not vomited at all; very giddy; fell on deck on one occasion; no headache. Temperature 99·2°; pulse 80. Ordered half a drachm of solution of hydrochlorate of morphia, and wound dressed.

14th.—Slept tolerably well; not so much pain about abdomen and thighs; no sickness or giddiness; wound looking healthy; bowels confined. Temperature 98·4°; pulse 72. Ordered two ounces of cathartic mixture, and wound redressed.—8 P.M.: Taken food well; bowels freely open; pain much less in abdomen. Temperature 98·4°; pulse 76.

15th.—Wound healing; patient going on well; water-dressing applied to the wound. Temperature 98·4°; pulse 64.

20th.—During the last five days patient has been progressing favourably. Temperature normal; pulse generally 70 or 75.

29th.—Wound healed; complaining of nothing; not a bad symptom during the last twelve days. Discharged to duty seventeenth day after the accident, patient working about the ship and going on well.

CASE 5.—Thomas J——, thirty-three, seaman. This man, going on shore at the Island of Santa Cruz, Aug. 12th, 1875, received an arrow-wound of the right leg an inch above the internal condyle. The arrow passed in in an oblique direction some two or three inches. The arrow was quickly removed, the wound, which bled freely, was at once sucked by one of the seamen, and a bandage applied tightly around the leg. Some fifteen minutes after the accident he was seen on board by the medical officers; the wound was a little enlarged, and carbolic acid and glycerine injected. A few hours after the accident he complained of a little pain around the wound.

Aug. 13th.—Slept well; no sickness, headache, or rigors; feels some stiffness about the wound; tongue clean; bowels regular. Temperature 99°; pulse 78. Wound dressed with a solution of carbolic acid and glycerine.—8 P.M.: Temperature 100·4°; pulse 88. A feeling of sickness during the day; has not vomited; slight headache; taken a little food; rather thirsty; no rigors; pain in leg much the same as this morning; wound re-dressed.

14th.—Passed a tolerably good night; felt a little sick; much less pain in the wound; bowels confined; no headache. Temperature 99·6°; pulse 92. Ordered cathartic mixture two ounces; linseed-meal poultice.—8 P.M.: No change in patient. Temperature 99·8°; pulse 80.

15th.—Little or no pain in wound; some discharge coming from it; patient's general health good. Temperature 98·8°; pulse 80.

20th.—Wound healing fast; no bad symptoms; progressing favourably. Temperature generally normal; pulse about 75 or 80.

25th.—No great change; wound fast healing.

31st.—Wound healed; patient complaining of nothing. Discharged to duty on the nineteenth day after the accident.

Remarks.—The first question which suggested itself to me was—Had the animal poison which is stated (by men who have been much among the South Sea Islands) to be on the arrows of these natives anything to do with the result of two of the cases—namely, tetanus and death? I cannot help thinking myself that the arrows were not poisoned; if they were, the poison could have had no effect. Three of the men hardly experienced (although their wounds were nearly as severe as the wounds of those who died) from beginning to end one bad symptom, not even enlargement of neighbouring glands, or any of the signs of a common dissecting wound, which I take it ought to have been the result if the arrows were poisoned.

The two men who died suffered but little for the first four or five days, when suddenly tetanus set in, assuming a severe form, and running a rapid course to death.

I think the cases are interesting as showing the fatal results of punctured wounds in the tropics and perhaps the sad circumstances connected with them.

LONDON HOSPITAL.

SEVERE CASE OF IODISM; TRACHEOTOMY.

(Under the care of Dr. Fenwick.)

This case of iodism, for the notes of which we are indebted to Mr. Roland Smith, resident medical officer, is one of the most remarkable hitherto recorded, and presents many points of interest. The patient was evidently unusually susceptible to the influence of the iodide of potassium, and suffered alarming symptoms from the effects of the drug, notwithstanding its combination with bicarbonate of potash, which, it has been stated, diminishes greatly the risk of iodism. The dose (ten grains) of the iodide was undoubtedly a large one to commence with, and is sufficient to give rise to disagreeable symptoms in most persons. It is the custom with many of those who are in the habit of using this drug largely to begin with small doses of three or four grains, gradually increased. By this means patients may often be made, in time, to take very large doses without any inconvenience whatever, although they showed at first an intolerance of the drug when given in full doses. Among the other circumstances worthy of note in this case was the absence of purpura or other cutaneous manifestations in the legs. In several cases that have come under our notice the walls of the hair and sebaceous follicles of the legs were the chief or only portions of the skin affected.

Frederick R——, aged thirty-five, was admitted to the hospital at 9.30 A.M. on the 9th of October in a semicomatose condition. His face was swollen and deeply congested, and the eyelids were puffy and red, as in an exaggerated case of facial erysipelas. The lips and tongue were extremely livid, the tongue being swollen and protruding from between the teeth. Very little air entered the lungs, and the epigastrium and intercostals sank in with each inspiration. There was croupy breathing, and on one occasion the cough was typically laryngeal. The pulse was scarcely perceptible. There was no dulness on percussion at the upper part of the sternum, no palpable interclavicular pulsation, and no bruit or other signs indicative of an aneurism pressing on either the trachea or the recurrent laryngeal nerves. Feeling certain that the obstruction was laryngeal, and noticing that the respiratory power was failing, Mr. Job, the house-surgeon, performed tracheotomy to prevent death, which seemed inevitable. The operation was not done a moment too soon, for breathing had ceased and the patient was pulseless for nearly a minute before the termination of the operation; but artificial respiration for a few seconds sufficed to restore life, and, before five minutes had elapsed, the patient expressed himself as much relieved. Colour returned to the lips and tongue, a good pulse was felt at the wrist, and the respiration seemed quiet and unimpeded. Without further examination at the time, the patient was sent into the ward.

At 12 o'clock, when seen by Mr. Smith, some pustules were observed on the face, and a papular eruption on the back of the hands and flexor aspect of forearms, the abdomen, chest, and lower extremities being exempt. At the back of the neck there were three pustules, and several on the ears. The patient was at this time breathing quietly. The temperature in the axilla was 99·4° Fahr.; pulse 100; respiration 36. There was no lividity of face, the eyelids were less swollen, no pustules on conjunctivæ, but very great chemosis. Owing to the umbilicated appearance of some of the pustules, the man was at once isolated. There had been no rigor, no pains in the loins, and no vomiting; but there was considerable headache.

The patient's previous history, as given by his wife, was as follows. Three years ago the patient had two similar attacks, and for each was treated in the London Hospital. On those occasions the breathing was not affected, but the throat was slightly sore. The eruption was confined to the nose, eyebrows, and forearms. Iodide of potassium was supposed to have been the cause of each, as that drug had been taken on both occasions. Excepting for rheumatism, he remained well until three months ago, when he became the subject of kidney disease (acute nephritis?). For the past month he has felt languid, and sometimes been obliged to give up work on that account. On Oct. 7th he woke up with rheumatism in his left wrist and a pain in the cardiac region. He got the following medicine from a medical man whom he consulted: "ten grains of iodide of potassium, ten drops of tincture of digitalis, fifteen grains of bicarbonate of potash in water, to be taken three times a day." Six doses only were given. After the fourth dose he thought he had caught a violent cold, and went to bed. He continued the medicine. At 1 o'clock on Saturday he woke up with a sensation of choking, called his wife, and tried to tell her he should choke; he could scarcely articulate. Poultices externally and inhalations of steam gave no relief. A neighbouring medical man was consulted at 9 o'clock, and his immediate removal to the hospital recommended. The patient was vaccinated when a child. Fifteen years ago he had small-pox; no history of syphilis could be obtained; family history was good; no similar illness or rash has occurred in anyone living in the street or neighbourhood where the patient resides.

Oct. 10th.—10 A.M.: Temperature 102·4° F.; pulse 130; respiration 21. 10 P.M.: Temperature 102·8°; pulse 136; respiration 24. On his face there were several pustules, some of them closely resembling variola of about the eighth to the tenth day. The eyelids were still swollen and œdematous, and there were spots also on his ear, hæmorrhagic-looking, and evidently containing bloody serum; others on his ears were much smaller, and did not contain pus, but were simply papules. There were three pustules on the back of the neck, none on the abdomen, chest, back, upper arms, or lower extremities, but a great number on the forearms, and in this situation the different varieties were very well marked. Some pustules were large and umbilicated, others not umbilicated, and varying in size so as in some places to resemble a simple papular eruption. The uvula was elongated, and the mucous membrane was somewhat swollen as if œdematous, but there was no eruption on the palate or pharynx. Urine copious in quantity, sp. gr. 1008, acid, albuminous, 1·4 per cent. of urea, and gave the characteristic reactions of iodide of potassium solution.

11th.—The tracheotomy tube was removed after forty-eight hours, as the patient could by that time breathe quietly through the natural passages. Soon after removal a quantity of adhesive mucus was expectorated through the wound and some by the mouth. Temperature 102·2°; pulse 104; respiration 24. The pustules on the face had commenced to scab; most on the forearms had a reddened areola, especially the umbilicated ones. Some of the papules were fading; nothing could be seen on palate or uvula. Laryngoscopic examination showed slight congestion of epiglottis and vocal cords. Urine still contained traces of iodine. Evening temperature 101°.

12th.—No fresh spots. The larger pustules had by this time commenced to dry up. The contents of the pustules seen microscopically consisted of squamous epidermic scales, pus-cells, and a great quantity of small spheroidal, transparent, non-nucleated cells, about the $\frac{1}{6000}$ or $\frac{1}{7000}$ inch in diameter. Although the urine was still albuminous, it did not contain any iodine. Morning temperature 100°; evening 99°.

13th.—Temperature normal. Rash almost disappeared, excepting one or two pustules which had burst and continued suppurating and discharging.

14th.—Patient convalescent. Urine still contained a trace of albumen.

Nov. 2nd.—Patient discharged quite well.

STANLEY HOSPITAL, LIVERPOOL.

SUCCESSFUL AMPUTATION AT THE HIP-JOINT.

(Under the care of Mr. RUSHTON PARKER.)

THE following case resembles in many respects those reported in the "Mirror of Hospital Practice" at page 591 of this volume, from the practice of Mr. Spence, of Edinburgh. The point to which special attention may be drawn is the fact, now established by abundant experience, that amputation at the hip-joint, in cases of disease in general, and in exhausting inflammation of joint and bone in particular, is by no means an operation of dangerous magnitude. Amputation at the hip-joint, and also high up in the thigh, in cases of accident, is performed under circumstances attended with a high mortality, and is a desperate undertaking. The influence of age was a second point in the patient's favour; but though the period of convalescence was very protracted, his safety seemed established by the third or fourth day after amputation.

In July, 1874, a boy six years of age was admitted suffering from inflammation of the right hip-joint of eighteen months' standing. There were sinuses, erosion of the head of the femur, real shortening to an extent of about two inches, much tenderness, little pain, and no emaciation.

Excision was performed on the 31st July, 1874, by a subperiosteal method very similar to that described by Sayre, and a double anterior splint of iron rod and iron wire was immediately applied. The acetabulum was found lined with granulations simply. During the after-treatment much purulent infiltration of the thigh took place, and by the month of November the patient was extremely emaciated and the discharges were very fetid. The application of a poultice of figs and milk (referred to by Billroth in the first page of his large work on Coccobacteria, from reading which the idea was derived) in a few days absolutely put an end to the fetor. But the boy was sinking, nevertheless, and it became evident that he must soon die if unrelieved from the extreme pain and tenderness. On 20th Nov. the consent of his parents to amputation was with difficulty obtained.

Amputation was performed on Nov. 21st, 1874, by transfixion of a long anterior and a shorter posterior flap. The blood of the diseased limb was previously returned into the rest of his body by elastic bandaging, and retained there by an india-rubber cord wound obliquely round the perineum and corner of the pelvis, over a pad laid on the external iliac artery. The cord was prevented from slipping down on the outer side by being looped over a bandage which was tightly wound round the pelvis transversely. The operation was almost bloodless, less than an ounce of blood being lost. Ligatures of carbolised catgut were used, and the child laid on his belly for the first few days after the operation, on account of a small sacral bedsore.

He lay in bed for three or four months, and was discharged on 24th April, just five months after the amputation. By that time he was fat and well, though a sinus or two remained. He was last seen about ten months after the amputation, and was quite well in general respects, though a single sinus still remained in the stump.

YORK COUNTY HOSPITAL.

OVARIAN TUMOUR; OVARIOTOMY; RECOVERY.

(Under the care of Mr. HORNBY.)

FOR the notes of the following instructive case we are indebted to Mr. S. Wreford, house-surgeon.

Sarah H——, aged thirty-six, a married woman and the mother of five children, was admitted on the 7th April, 1875, suffering from an ovarian tumour.

Three days after her admission Mr. Hornby tapped her, and drew off 408 oz. of dark-greenish viscid fluid.

On the 22nd April she was discharged, with the understanding that she was to return as soon as her abdomen became inconveniently distended.

After remaining at home for two months, she was readmitted on the 23rd June with her abdomen very much distended, measuring 44½ in. in circumference. Her general health being very good, Mr. Hornby decided to perform ovariotomy.

July 6th.—The patient being put under the influence of ether, and the bladder emptied with a catheter, an incision was made in the median line commencing just below the umbilicus, and extending downwards for about 5 in. When the peritoneum was reached it was at once seen to be intimately adherent to the sac, and in separating the adhesions in front a small opening was made into the sac. The aperture was immediately enlarged by an effort at vomiting, and through this opening some of the contents began to escape. The patient was immediately turned on to her side, and a small quantity of fluid having been allowed to escape, a ligature was placed round the opening to prevent, if possible, any further escape of fluid into the abdominal cavity. After breaking down some of the adhesions in front, the greater part of the fluid was allowed to escape by turning the patient again on to her side. The sac was intimately adherent to the peritoneum throughout its whole extent, and great difficulty was experienced in separating the connexions. Mr. Hornby, however, succeeded at length in breaking down all the adhesions with his fingers, but during this forcible detachment it was impossible to avoid tearing the sac here and there, and there was consequently a further escape of fluid. The cavity of the abdomen was well sponged out with tepid water, a clamp applied to the pedicle, and the edges of the wound accurately adjusted with wire sutures. During the operation, which lasted for about an hour and a quarter, the liver, uterus, and portions of the intestines were distinctly seen to be covered by peritoneum. Immediately after recovering from the effects of the ether, the patient complained of great pain in her abdomen, which was relieved by a hypodermic injection of a third of a grain of morphia. Vomited several times during the afternoon and evening. Evening temperature 101·4° F.

July 7th.—Had a comfortable night up to 5.45 A.M., when she began to vomit again. Complains to-day of a great deal of pain at the pit of the stomach, more especially after drinking. Ordered an enema of an ounce of brandy with an egg every four hours. Morning temperature 100·4; evening 103°.

8th.—Vomited very frequently during the night, but had no pain; slept for about four hours. Tongue clean and moist. Ordered to have nothing but ice and champagne by mouth, and to continue the nutrient enemata. Morning temperature 100·2°; evening 101 .

9th.—Has not had so good a night. Two of the enemata given during the night were not retained. Ordered to have thirty minims of tincture of opium with the next. Morning temperature 99°; evening 100 2°.

10th.—Slept soundly the greater part of the night. During the afternoon had some mutton broth twice at her own request, and it caused no vomiting. There is no abdominal pain or tenderness.

12th.—The enemata, not being retained, were ordered to be discontinued. Has had no vomiting since the 10th. Ordered six ounces of port wine daily, instead of champagne.

13th.—Clamp removed. Wound looks very healthy, there being scarcely any discharge. Not having had an action of the bowels since the operation, a castor-oil enema was administered, which acted freely.

From this time the patient progressed favourably without a bad symptom, and was discharged well on Sept. 1st. A letter received from the patient a month after her discharge stated that she was in perfect health, and had been so ever since.

Observations.—This case is instructive as showing how roughly, under certain conditions, the peritoneum may be handled without serious consequences resulting. The sac was, as before stated, adherent to the peritoneum throughout its whole extent; it was forcibly detached by the hand; some of the fluid contents of the sac escaped into the peritoneal cavity, and had to be washed out with a sponge; and yet the patient recovered without a bad symptom. In the process of adhesion the peritoneum had doubtless undergone some alteration which rendered it much less liable to take on inflammatory action.

ROYAL HANTS INFIRMARY.

CASE OF STRANGULATED INGUINAL HERNIA; OPERATION; RAPID RECOVERY.

(Under the care of Mr. LANGDON.)

C. J——, aged fifty-five years, a labourer, was admitted into the hospital at 11 P.M. on Sept. 4th, suffering from strangulated oblique inguinal hernia in the left groin. He had never worn a truss, and for thirty-six hours had suffered from the usual symptoms of strangulation. He had consulted his parish doctor, who had employed taxis after he had been placed in a bath. It was decided to operate at once, and, after the patient had been placed under the influence of chloroform, this operation was completed without opening the sac. There was very little hæmorrhage, and the edges of the wound were brought together with ordinary silk sutures. Carbolic oil, one in thirty, was applied, and the patient removed to bed.

Sept. 5th.—Patient slept well, and feels very comfortable; no sickness or pain. Pulse 84. Wound not dressed.

6th.—Feels quite well; bowels moved slightly. Wound was found quite healed. All the sutures were removed.

7th.—Patient allowed to get about the ward, wearing a truss. Bowels moved freely.

10th.—Discharged cured.

The diet consisted at first of slops, and was gradually increased.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE ordinary meeting of this Society was held on the 9th inst., the chair being taken by Mr. Chas. Brooke, V.P., and subsequently by Sir Wm. Jenner. The subject for the evening was that of Croup and Diphtheria, introduced in a paper by Dr. Semple. There was a large attendance of Fellows in anticipation of a lively debate; nor were they disappointed, for, although Dr. Semple's paper was almost entirely historical in nature, it was followed by a most admirable statement of the points at issue by Dr. West, Sir Wm. Jenner, and Dr. Dickinson. The meeting resolved, on the motion of Dr. West, to refer to the Council the question as to the expediency of appointing a committee of investigation into the relations between croup and diphtheria. At the close of the meeting Dr. Hughlings Jackson introduced a patient affected with spasmodic movements of hemiplegic distribution.

Owing to the length of Dr. SEMPLE's paper, "On Diphtheria and its relations to so-called Croup," it was read in abstract only. The author began by setting forth the reasons which induced him many years ago to regard as erroneous the doctrines formerly held in Great Britain on what was called "croup," and to propose a new nomenclature for the maladies which that term seemed to include. These reasons were based on his study of the French writings on what was called "diphtheria," together with his own clinical researches into the pathology of the disease so named by Bretonneau. That physician and other French authors regarded diphtheria when it attacked the trachea as synonymous with membranous croup. When the disease now called "diphtheria" broke out at Tours, Bretonneau had previously seen only two cases of croup (to use his own language); but when it showed itself as an epidemic, he studied it carefully in combination with his then pupils, Velpeau and Trousseau. They found a remarkable uniformity in the symptoms and post-mortem appearances, and from the constant presence of the false membrane, Bretonneau applied to the malady the name of "diphthérite." The physician of Tours, however, not only studied the actual features of the disease as it presented itself to his notice, but he endeavoured moreover to solve the important question whether any such epidemic as he then witnessed had ever presented itself before in the history of the world, and the result of his inquiries was to convince him that his "Diphthérite," although under different names, had existed from all antiquity, and had been described in the earlier medical writings. Dr. Semple, however, could not agree with Bretonneau on this point, for he had failed to find in the original Greek of Hippocrates or Aretæus, or in the Latin of Celsus, a description of the false membrane lining the trachéa, as in "diphthérite." But from researches into the writings of a more recent period, Dr. Semple is convinced that epidemics of the disease have been accurately described by Spanish, Italian, Sicilian, Swedish, and French physicians, including Herrera, Fontéda, Villa Real, Sgambati, Carnevale, Nola, Glisi, Cortesius Wilcke, Marteau de Grandvilliers, Bard, Starr, and Francis Hane, all of whose works, together with those of prize essayists in France at the commencement of the present century, Dr. Semple had carefully read. In the celebrated essays the authors evidently include under croup three distinct diseases. Soon after the publication of these essays Bretonneau began his researches, in which he confined the term "croup" to those cases in which there was a distinct false membrane in the windpipe, and this view was adopted by his successors of the French school, such as Trousseau, Guersant, Bouchut, Empis, Daviot, Valleix, Barthez and Rilliet. Passing to his own experience, Dr. Semple detailed a few cases of laryngeal diphtheria, and exhibited to the Society a preparation of the larynx and trachea, with the false membrane *in situ*, obtained from the most recent of them. He had compared this specimen with those described as "croup" in the museum of the Royal College of Surgeons, and found that they were exactly identical. He further showed that the German as well as the French pathologists hold the membrane of croup and tracheal diphtheria to be identical, but he deprecated the wide application of the term "diphtheritic" to hospital gangrene, dysentery, &c., as used by Virchow. The author of the paper had arrived at the following conclusions from his clinical and historical researches:—That the terms croup and diphtheria are not to be regarded as synonymous, but that the term croup, as generally employed, comprises at least three very different affections, namely—1, laryngismus stridulus; 2, infantile laryngitis; and 3, tracheal (or, rather, laryngo-tracheal) diphtheria. That diphtheria (although under many different names) has probably existed from all antiquity, and although its features have not been described with sufficient distinctness by the ancient Greek and Roman medical writers, its epidemics have been clearly indicated by Spanish, Italian, Sicilian, French, German, Swedish, American, and British authors from about the end of the 16th century to the present day. That diphtheria as an epidemic did not visit London until about the year 1858 or

1859, the last European epidemic being that present in Florence and its neighbourhood in 1869–70. But although diphtheria as an epidemic has prevailed only at fitful and irregular intervals in the history of the world, sporadic cases have always existed.

Dr. West said that he had hoped to hear Sir William Jenner speak on a subject to which he had given so much attention, but that as no one else had risen, he would like to say a few words. Although our best thanks are due to anyone who labours to throw light upon the question of the relations between croup and diphtheria, yet he doubted whether much benefit could be gained from archæological details, interesting as they are. For wonderfully accurate as were the older writers in their descriptions of disease, they looked only to the more striking and evident phenomena, and disregarded those minute details which are to us so essential in making an exact diagnosis between two conditions which may have a superficial resemblance. It was just the same with the older anatomists, who left untouched so many of the finer points, but gave full and accurate descriptions of the more evident. A parallel to this was to be found in the history of diphtheria in olden times. We know now that when the local disease has passed away the series of morbid manifestations still goes on, in a large number of cases, in the form of disorders of the nervous system. Yet even this striking fact had not received mention even by Bretonneau himself. Dr. West compared this oversight to the manner in which the eruption in typhoid fever, when he was a student, passed unnoticed; nor had he himself any note of paralytic symptoms supervening upon cases, which must have been diphtheria, that he had seen in his early days. The question, said Dr. West, is really this: "Croup," as described by Cheyne, a most keen observer—and as so many of us know it—sets in after catarrhal symptoms, with first some degree of hurried respiration, then a noisy cough, then dyspnœa, great anguish, and, if no relief be obtained, a rapid termination in death from suffocation; whilst, if the progress of the disease be towards recovery, this is rapid, and follows on the subsidence of the local manifestations. Cases such as these had been recorded, in which improvement had occurred under bleeding. Cheyne mentions some—one in particular, in which venesection was performed three times in rapid succession, with good result; and he himself (Dr. West) had once bled from the jugular, with recovery. He would ask, was not that a different disease from "diphtheria," where there was rarely any preliminary catarrh, where the child was taken ill with slight febrile disturbance, pain in swallowing, enlargement of the glands in the neck, with great prostration, where laryngeal symptoms *may* set in, but in a totally different manner from their mode of onset in croup? In the one disease there was exudation of membrane on the fauces, in the other it was wanting; in the one there was albumen in the urine, in the other this was nearly always absent; then in the one, when the symptoms had passed away, when venesection, if had recourse to, would inevitably kill the patient, there was frequently left a long train of disorders of the nervous system. Are these two diseases, or are they only different types of one and the same affection? Both are characterised by a deposit of false membrane, in one beginning in the fauces, in the other commencing in and remaining limited to the larynx. Are we to believe that both are communicable by contagion? He must admit that they did not differ from one another more than the simplest forms of scarlet fever did from the most malignant. Hitherto, however, his opinion had been that they were essentially distinct—the one being a local inflammatory disease of the larynx, the other being due to what might for want of a better name be termed a blood-disease—a constitutional affection. This belief he still held, although he must confess his belief was by degrees growing less positive than before. Dr. West concluded an admirable speech by pointing out that the question could not be settled satisfactorily by any one or more observers acting independently, and he urged the appointment of a committee to inquire into and report upon the subject. The points requiring settlement might be stated as follows:—1. Do the two affections prevail epidemically at the same time? 2. Do the two prevail at the same time, and in the same locality, or is their locality different? Thus, it is well known that croup is far more prevalent in rural than in urban districts—the proportion of cases met with, for example, in Sussex and Cumberland being to those in Liverpool as three to one. 3. Does it ever happen that of two members of a family attacked at the same time the one has "croup" and the other "diphtheria"? 4. Is the disease "croup," as described by Cheyne, ever accompanied by albuminuria, and if so to what extent? 5. Are both diseases followed by symptoms of disorder of the nervous system? Should a committee of the Society be appointed to investigate such and the like questions, he thought it might enable us to arrive at a decision alike satisfactory to individual workers and to the profession at large.

Sir William Jenner said that he had come to the meeting rather to listen than to speak, and that he had declined to come and preside on this occasion, because he had, to a certain extent, committed himself to one view of the question. He, like Dr. West, had held for a long time that croup and diphtheria were distinct diseases, and had published that opinion; but a larger experience, among all classes of persons, had compelled him to alter those views. It now seemed to him that the evidence is all but absolutely conclusive on the other side. He would hesitate to say it was proved, but the facts were strongly in favour of the doctrine of identity. The grounds which led him to change his opinion were as follows:—1st. Albuminuria, a symptom held to be characteristic of diphtheria, he had seen in genuine "croup"—croup coming on with catarrh, with no exudation in the pharynx. He had seen several times in such cases the urine loaded with albumen. 2nd. He had seen a surgeon in attendance on a case of diphtheria contract laryngo-tracheal membranous disease, and, moreover, in that case the paralytic sequelæ followed. 3rd. Then the *sthenic* character of croup was not distinctive, for some cases of membranous pharyngitis (diphtheria) presented as great force of febrile disturbance as he had ever seen; and, speaking generally, he could not believe that diphtheria was so asthenic as commonly taught. He thought it was quite an *a priori* view to assume that bleeding would be necessarily fatal in such cases, and, in spite of the great powers of observation of Cheyne, he (Sir William) submitted that that observer had confounded catarrhal with membranous laryngitis in those cases which he records as being relieved by venesection. Similar mistakes had occurred before, as in the epidemic of relapsing fever in Edinburgh in 1818, when the disease was mistaken for typhus, and large bleedings were practised, and this mode of treatment held up as of value in arresting typhus in its early stages. Then the fact that paralytic sequelæ never or rarely followed croup was easily explained, because as soon as diphtheria attacks the larynx recovery is infinitely rare. With respect to the distinction between croup and diphtheria as to *cause*, Sir William stated that he had met with cases of true diphtheria which undoubtedly came on from exposure to cold, and he quoted two instances of this. Finally, he could not see a single reason for believing in the non-identity of the two affections.

Dr. Dickinson said that he could not presume to put forward his opinions as of much weight, but from his long connexion with the Hospital for Sick Children, he had necessarily seen much of the diseases in question, and had been led to form some conclusions on the subject. From what he had seen, he felt bound to maintain the old view as to the two affections being wholly distinct from one another. The views expressed so ably by Sir Wm. Jenner seemed to him to amount to this: that there only existed *one* cause for membranous inflammation of the larynx, that cause being some zymotic poison. But he (Dr. Dickinson) submitted that the laryngeal mucous membrane, under any kind of irritation, tends to throw out membranous exudation, and he instanced such irritants as hot water, foreign bodies, &c. Exposure to cold acts in the same way, and so does the special poison of diphtheria. Assuming there to be two causes, a difference in the symptoms ensuing can be traced; for in the one there is tendency to prostration and death by asthenia, and in the other the disease runs a sthenic course, there is a limitation of the false membrane to the spot where it is formed, and there is a tendency to death by asphyxia. He would concur in Dr. West's suggestion, that the question should be referred to a committee.

Dr. Semple, in closing the debate, expressed his gratification in a long and animated speech, at the course in which opinion was tending, as confirmatory of much that he had long held and enunciated on other occasions—viz., that laryngeal diphtheria and membranous croup were identical, a view which he thought was fully borne out by the historical investigations that formed the basis of his paper.

It was then moved by Dr. WEST that it be referred to the Council to consider the expediency of appointing a committee to consider the relations existing between the diseases commonly known respectively as "membranous croup" and "diphtheria." The motion was seconded by Dr. DICKINSON, and was carried unanimously.

Dr. HUGHLINGS JACKSON then brought forward a patient suffering from a spasmodic affection of the right arm and leg. The arm was the more affected; it was constantly moving about, and had been a source of trouble to the patient for eighteen months, requiring constantly to be kept controlled; and even during sleep the man was obliged to lie upon his arm to prevent the movements. Dr. Jackson said that he had brought the case down in order to elicit opinions as to the advisability of division of the nerves of the arm. Division of the median had been suggested by Dr. Weir Mitchell, but on theoretical grounds Dr. Jackson was averse to cutting off too much of the nerve-supply of the upper limb, lest the leg should become more affected. The pathological condition at the root of the affection was very obscure, and all Dr. Jackson could say was that it pointed to disease of the left cerebral hemisphere. He had seen something similar to it, but to a far less marked extent, in children who had been hemiplegic in infancy. The history of the present case was to the effect that seven years ago the man was struck on the left side of the head, the blow being followed later by right hemiplegia; the spasmodic condition, however, was of eighteen months' duration. The movements cease under chloroform, but there remains persistent contraction of the pronator muscles. Woorara had been given with temporary relief, and (contrary to the opinion of anti-vivisectionists) with the production of greater anæsthesia. It was not the "athetosis" of Hammond, although it was similar in some respects to it. Dr. Jackson promised to bring the results of operative measures before the Society.

The meeting then adjourned.

Reviews and Notices of Books.

The Anatomy of the Lymphatic System. II. The Lung. By E. KLEIN, M.D. London: Smith, Elder, and Co.

PROF. KLEIN has followed up his admirable researches on the lymphatic system of the serous membranes by a complete and valuable series of investigations into the arrangement and distribution of the lymphatics of the pulmonary pleura and lung. He has studied them in the guinea-pig mainly, but also in the dog, cat, rat, rabbit, and man. The chief results to which the author has been led are, that there are three freely anastomosing systems of lymphatic vessels in the lung. The first system is found in the walls of the alveoli, and commences as irregular lacunæ and anastomosing canals, which soon form vessels with a special endothelial wall. The more superficial or subpleural lymphatics are arranged in a network from which efferent trunks proceed in the pulmonary ligaments to the root of the lung. The deeper set are perivascular, and are replaced in some parts by lymphatic spaces, lined by connective-tissue corpuscles. A network is formed around the large bloodvessels, and the trunks pass deeply to the root of the lung. The second system is peribronchial, and begins in the outer part of the mucous membrane, by similar lacunæ and anastomosing canals, lined also by connective-tissue corpuscles. After forming a plexus, the larger trunks join the perivascular lymphatics. The third system belongs to the pulmonary pleura, and begins in the same manner; but the canals are fewer, and each lacuna is lined by a connective-tissue cell-plate. These are in *direct* communication by stomata with the cavity of the pleura, and their efferent trunks discharge their contents into the subpleural lymphatics. The communication of the peribronchial and perivascular radicles with the free surface of the bronchial mucous membrane and the alveolar cavities is *indirect*, by means of what the author calls "pseudo-stomatous" tissue. This is a cellular tissue placed between the true endothelial cells. It is composed of a branched and nucleated body, one process of which is turned towards the free surface, and the other towards the deep part of the mucous membrane, where it is continuous with the connective-tissue corpuscles lying in the lymph spaces of the mucosa. When distended it forms a free communication between the surface and the lymphatics; and as Mr. Watney has found analogous structures in the alimentary canal, we seem to be advancing to a clearer conception of normal and pathological absorption. In guinea-pigs unstriped muscular tissue is found beneath the pleura as a definite layer, and lymph spaces exist between the fasciculi. Lymph follicles are contained in the wall of the peribronchial lymphatics of these animals and of rabbits.

The anatomical details are supplemented by some interesting pathological observations on septic pleuritis and on the relations of the lymphatic system to the processes of artificial tuberculosis in guinea-pigs, and of acute miliary tuberculosis in the human subject. The changes in the endothelium covering the inflamed pleura are exactly similar to those found on the serous surfaces in peritonitis. The endothelial cells around the stomata are found in a germinative condition—i. e., they become granular, polyhedral, and their nuclei show more or less distinct constrictions. In addition, the matrix is thickened by an infiltration of lymphoid cells succeeded by an increase in the connective tissue, the lymphatic spaces are filled with lymphoid cells, and in the guinea-pig the subpleural muscular layer hypertrophies. In chronic pyæmia and artificial tuberculosis induced from the pleural cavity, nodular or patch-like growths exist in great numbers in the superficial parts of the lung. These are the alveoli, at first lined with changed epithelial cells, and then with cells much resembling lymphoid cells. They finally undergo central caseation.

Dr. Klein's account of artificial tuberculosis in guinea-pigs differs materially from the observations of Sanderson and Wilson Fox. The latter regards all granulations permeating the lung as analogous in appearance and structure, being all semi-transparent and composed of lymphatic tissue. Sanderson did not distinguish between the perivascular and peribronchial position of the nodules, as did Wilson Fox, but he separated the peribronchial granulations (hyperplastic normal adenoid tissue) from the semi-transparent miliary nodules (blocks of lobular catarrhal pneumonia). To these two kinds of granulations the author adds a third—viz., semi-transparent, cord-like structures, situated in the adventitia of the minor branches of the pulmonary bloodvessels. These perivascular cords are composed of fibres forming a network in which lymphoid corpuscles abound. Their formation is due to two processes—(*a*) an emigration of colourless blood-corpuscles into the perivascular lymphatics with the subsequent development of a stroma, and (*b*) a growth of a network of fibres between a collection of lymph-corpuscles lying outside a lymphatic vessel. The former is endolymphangeal, the latter is perilymphangeal. These perivascular cords were the only abnormal elements present in some lungs studded with miliary granulations, and he therefore considers their appearance as the earliest symptom of the process of artificial tuberculosis. He agrees with Sanderson that many granulations are composed of trabeculæ representing the thickened alveolar septa, and of spaces which are the alveoli filled with products of the alveolar epithelium. These products are epithelial cells more or less enlarged, and the so-called “giant cells.” Lymphoid cells are very scarce, and the appearances are evidently due to a catarrhal pneumonia in intimate connexion with the perivascular cords. These are the only nodules that undergo caseation, and are especially abundant in the more superficial portions of the lung.

The author accepts Buhl’s description of a miliary tubercle in man. Young tubercles possess a matrix of peripheral connective tissue arranged circularly, and a homogeneous reticulum without nuclei, enclosing cells smaller than lymph-corpuscles, multinucleated giant cells, and epithelial cells. Buhl considers that all cases of acute miliary tuberculosis are caused by a disseminated catarrhal pneumonia, and that this process differs from genuine desquamative pneumonia only in the presence of giant cells among the germinating epithelium of the alveoli. From an examination of the lungs of seven children who died from undoubted acute miliary tuberculosis, Klein has come to the conclusion that these cases have *at the beginning only* the character of desquamative pneumonia. In the earliest stages the nodules correspond to groups of alveoli and infundibula, distended by a fibrinous material containing granules and small cells. This exudation disappears, and is succeeded by groups of cells, or by one multinuclear giant cell, both derived from the alveolar epithelium. The interalveolar tissue is thickened and transformed into a retiform tissue, which contains lymphoid corpuscles. The giant cells give rise to nucleated cells, which increase the retiform tissue, and also to cells resembling lymphoid corpuscles lying in the meshes of that tissue. Commencing from the centre of the tubercle, the giant cell, as well as the surrounding tissue (after conversion into a dense fibrillar substance) degenerates, and becomes a hard, firm, and débris-like mass. After these necrotic changes have begun, the bloodvessels are surrounded with a true adenoid tissue analogous to the perivascular cords above described, and spherical collections of lymphatic tissue appear in the adventitia of the bronchi.

Thus it would seem from these investigations that in acute miliary tuberculosis the pneumonic process precedes the increase in the adenoid elements, whereas in the artificial form induced in guinea-pigs the formation of a lymphatic structure (perivascular cords) is the primary change, and the blocking up of the alveoli with epithelial derivatives is of secondary occurrence.

We cannot conclude without expressing our very high opinion of the value of Dr. Klein’s work. The numerous plates, for the execution of which the Government Grant Committee of the Royal Society have found the means, are models in clearness and delicacy of outline.

A Practical Treatise on the Medical and Surgical Uses of Electricity. By George M. Beard, A.M., M.D.; and A. D. Rockwell, A.M., M.D. Second Edition. London: H. K. Lewis. New York: W. Wood and Co. 1875.

An immense amount of labour has been spent upon this work, a second edition of which has just been issued. The book contains a great mass of information, and nearly all the more important facts bearing upon the employment of electricity for the relief of suffering, which have been established of late years, are herein recorded. The first hundred pages are devoted to “Electro-physics,” and in them the subject of electricity in general will be found treated of nearly as fully as in works which are entirely devoted to physical subjects. Electro-physiology occupies the next hundred pages, and in them much that is certain will be found diluted by a mass of assertions which the profession at large are not, we believe, inclined to accept. Take, for example, the statement at page 155, that “when the *galvanic* current is applied to a living and healthy motor nerve in a healthy man, contraction takes place only *on closing the circuit*. This fact is constant with either pole, and any direction of the current.” If the authors will place the anode over the ulnar nerve of the first available man, use a current of moderate power and *open* the circuit, contraction of muscles supplied by the ulnar will assuredly follow. A mistake such as this is certainly a curious phenomenon in so pretentious a book.

Brenner’s investigations on the reactions of the acoustic nerve to electric stimulation are given at great length. He asserts, and of the general truth of the assertion there can be little doubt, that on placing the cathode in the ear and *closing* the circuit a rumbling or sharp ringing noise is produced, and on placing the anode in the ear and *opening* the circuit a noise of different character is produced. These are facts which anyone who is not afraid of a little pain or annoyance may roughly verify on himself. The authors’ description of the mode of performing the experiment, however, is a little terrible.

> “The operator should proceed calmly and with self-command. After the patient is in position, with his head inclined on the back of the chair or lounge, and one of the electrodes fastened to or held in the hand opposite the ear to be experimented on, a little warm salt water should be dropped in, which can be very conveniently done by squeezing the small quantity necessary to fill the external auditory canal from a small sponge or funnel-shaped glass; and the other electrode firmly pressed on the tongue. It is well to begin with a small number of elements, and gradually increase until a reaction is obtained. The reaction will usually appear when the current is strong enough to produce a contraction of the facial muscles. The patient should at all times be continually and repeatedly questioned, especially if he is unaccustomed to the treatment; for, at first, he may be so distracted *by the flashes of light before his eyes, the contractions of the facial muscles, the nausea, the metallic taste, and the noise of the water in the ear*, and especially by the *pain*, that he may be unable at first to distinguish the true character of the reaction.”

The above extract is a fair sample of the literary style of the authors. The slight pomposity of the first sentence, the almost needless details in the parenthesis, the double adverbs qualifying “questioned,” the capricious use of italics, and the ungrammatical repetition of the words “at first,” are the kinds of blemishes that are abundant on every page.

The next 200 pages are devoted mainly to descriptions of apparatus and the methods of using them, and this perhaps is the most reliable part of the book. What may be called the clinical chapters are comprised in the remaining half of the volume, and we are bound to say that the 250 cases, taken mainly from the authors’ practice, are singularly barren in those facts which serve to increase our knowledge of the pathology or diagnosis of disease, and in this respect the volume before us forms a marked contrast to the classical, original, and thoughtful work of Duchenne. There are assertions, too, in this portion of the work which, if not due to carelessness, show a surprising ignorance. At p. 519 we find:—“The fact that in facial paralysis of central origin the electro-muscular contractility is unimpaired, while if the nerve itself is the seat of the injury, the muscles *refuse to respond to either current*, materially aids us in diagnosis.’ Again, at p. 536:—“In cases of progressive muscular atrophy the electro-muscular contractility is either diminished or destroyed.” If a student had written the chapter on “locomotor ataxia,” in answer to an examination question, he must assuredly have been plucked, so much is the description of the disease there given at variance with the generally received description. The work, in short, is one which we should be sorry to see in the hands of any student; and, although it will increase the fame of its authors as electricians, it will scarcely improve their reputation as physicians. There is in it, however, a great deal of information of a practical kind which will be welcome to those who are working at the subject of electricity, and, when another edition is required, if the authors will content themselves with simply erasing about half of the present volume there is no reason why the remainder should not be a convenient, reliable, and most valuable treatise on the subject to which it is devoted.

A Dictionary of Science, Literature, and Art. Edited by W. T. Brande, D.C.L., F.R.S.L. & E., late of Her Majesty's Mint; and the Rev. George W. Cox, M.A., author of a "History of Greece," "The Mythology of the Aryan Nations," &c. New Edition, revised. London: Longmans and Co. 1875.

We recently noticed the new edition of Ure's valuable dictionary. We have now before us another edition of the equally well-known work of Brande. The wider plan of Brande's dictionary, while it confers upon it a more extended usefulness, renders it of necessity a less complete book. Even the three bulky volumes are insufficient for completeness, and while very much that is important is included, it is not surprising to find that much of equal importance has been omitted. It seems almost like ingratitude to write thus of a book which to every student is so useful, and we have no wish to find fault with an editor for defects which he would be almost more than mortal if he avoided. But the truth is a book of this kind is always to some extent disappointing. Everything is to be found in it except just the small fact you want: that is absent.

The scientific revision which ten years had rendered so necessary has been effected fairly well, though not so well as it should have been. The new notation in chemistry has been adopted generally, but not always (*vide* "Clay"), and the formulæ are for the most part correct. Many new discoveries are introduced, but many—as, for instance, the synthesis of alizarin and of tartaric acid—are omitted. In physics we miss many of the modern phrases, such as "Ohm," "Farad," &c., which have become important, and there are similar deficiencies in physiology. Hoppe-Seyler's discoveries, for example, are not noticed under the heading "Blood," and glycogen is omitted altogether. Dozens of other defects of the kind might be pointed out, many of them glaring ones, and we hope that another new edition will not be attempted without a more stringent revision. But, after all, the labour requisite for a new edition of such a work is great, and we are glad to admit that in spite of some defects, Brande's dictionary is still a valuable and, in the main, trustworthy work of reference.

New Preparations.

QUINETUM: THE PURE ALKALOIDS OF EAST INDIA RED BARK.

(THOMAS WHIFFEN, BATTERSEA.)

The increasing cultivation in India of the *chinchona succirubra*, which, as our readers are aware, yields a large proportion of alkaloids other than quinine, renders it a matter of great importance to introduce these alkaloids as far as possible into medical practice. From the evidence of Broughton, De Vrij, and other well-known authorities, it appears clear that they are little behind quinine in medicinal value. Somewhat larger doses are required than when pure quinine is used; but the results obtained with the mixed alkaloids in India, where, as Mr. Broughton states, pure quinine is now seldom made, are highly satisfactory. It is, indeed, not improbable that some patients who are unable to take pure quinine would not find the same difficulty with the mixed alkaloids. However this may be, it is evident that economical reasons, which with so expensive a drug are of no little importance, should induce medical men to give a fair trial to the preparation.

We have analysed samples of the so-called quinetum and its sulphate, and find that they are exactly what they profess to be.

RICHARDSON'S COD-LIVER OIL EMULSIONS.

We have analysed three preparations bearing the above title, all made by Messrs. John Richardson and Co., Leicester. One is the simple emulsion, another contains quinine, and the third phosphorus. They are, therefore, correctly described. The emulsions are well prepared, have little smell, and are free from rancid taste. They are, in our judgment, more easy to take and less liable to cause nausea than the pure oil, and are, therefore, likely to prove valuable, as they certainly are elegant remedies.

MAGNESILYNE, OR MAGNESIUM CITRATE.

(KINMOND AND CO., LEAMINGTON.)

This preparation, which effervesces freely with water, contains magnesium carbonate and citric acid. We have therefore now a "granular effervescing citrate of magnesia" in fact as well as in name. The application of the title to the common preparation is, in our opinion, thoroughly misleading, and should at once be discontinued.

DR. OSCAR LIEBREICH'S PEPSIN-ESSENZ.

(CORBYN AND CO.)

This preparation, made by a well-known Berlin manufacturer, and introduced by the famous name of Dr. Liebreich, is a solution containing some alcohol, though not enough, it is said, to hinder the activity of the pepsin. The trials we have made with it do not convince us of its superiority over other preparations, and without further evidence we hesitate to recommend it.

D. D. ENCORE WHISKY, DOUBLE DISTILLED.

(BERNARD AND CO., LEITH.)

This new competitor for public favour is pale yellow in colour, mild in flavour, and has but little smokiness, though it has the usual pleasant peaty smell characteristic of Scotch whisky. It is very faintly acid, and analysis proves that it is remarkably free from the fusel oil with which new whisky is generally contaminated, and to which much of the injurious effects of spirit-drinking are with some reason ascribed. The "D. D." is therefore more wholesome and pleasanter, except to a vitiated palate, than the fiery spirit so often sold. On the other hand, however, we cannot admit that it is equal in flavour to that fine mellow fluid which we are sometimes fortunate enough to meet with, from which fire and rawness have alike been removed, not by rectification, but by the subtle chemistry of time.

JOHNSTON'S PATENT CORN FLOUR.

(J. AND G. JOHNSTON, PAISLEY.)

The sample we analysed was well made and quite free from adulteration. Although we always regret that the term flour has been applied to an article which everyone knows to be, like arrowroot, a nearly pure starch, there would now be great difficulty in changing the name, and the article itself has become a necessity. The new "brand" is decidedly superior to one or two others with which we compared it, though we do not assert that it is superior to all.

brated flight in the opposite direction, in which the flier, also speeding

> "With hop'd success,
> Threw his steep flight in many an airy wheel."

Not the least instructive portions of Mr. Radcliffe's address were those in which he showed how the fallacies which had so long hampered English epidemiological research still largely hampered like research in India, where the difficulties under which it is pursued are peculiar, and he might, perhaps, have added, yet imperfectly understood by those chiefly concerned in knowing them.

Through the report that we published last week and the notice that appeared in our advertisement columns, it will have become fully known that the Council of the College of Surgeons has at last determined to appoint a set of Examiners in Anatomy and Physiology, separate and distinct from those in Surgery and Surgical Pathology. The former will consist of nine members, to be elected from the Fellows of the College, and will be known as the Board of Examiners, as distinguished from the Court of Examiners or the Examiners in Surgery. The election of members of the Board will be made by the Council some time during the next month, all Fellows of the College desirous of becoming candidates for the office having been invited to send in a written application to the Secretary on or before Saturday, the 20th inst. The members of the Board will be elected annually, and no Examiner will be allowed to hold office for more than five consecutive years, but after an interval of one or more years he will again be eligible for election.

It must be confessed that the ensuing election is to be looked forward to with some degree of anxiety, for the constitution and quality of the successive Boards will be greatly influenced by the nature of the first. The task that the "Committee on Examinations in Anatomy and Physiology" will be called upon to perform, when it has recommended to the Council the candidates deemed fittest for election, will be both difficult and delicate; but the nice discrimination and good sense of the Committee—which consists of Sir James Paget, Messrs. Prescott Hewett, John Birkett, Hilton, Hancock, and Marshall—may be trusted to bring matters to a satisfactory issue. One serious difficulty that the Committee will have to contend with will be to distinguish between candidates who are qualified by previous training and experience to undertake the duties of examinership, and those whose only qualification for the post is the ambition to become members of the Board; in other words, the Committee may not find it an easy matter to make their selection. As to the principle of election, also, there will be some difficulty. Seniority in the Fellowship should of course be looked upon as an extra claim by those who are otherwise competent for the office; but it is to be hoped that seniority alone will not outweigh other more important qualifications. Among the junior surgeons in London there are many who are eligible for the office, so that, if the Committee make its recommendations regardless of the seniority of the candidates, great good will result as far as the examinations in Anatomy are concerned. But the case is different as regards Physiology. Few of the teachers of Anatomy in the metropolitan schools are reputed to have made a special study of Physiology, and the Council may find that, in order to ensure a sufficiently high standard in the examinations in Physiology, it will be necessary to appoint at least two or three professed physiologists. This should be done, even if these Examiners shall have to confine themselves to Physiology; and it is rumoured that such a selection will actually be made.

The new arrangements will, we believe, be completed in time for the January examinations, the results of which will afford some indication of the influence likely to be wrought upon the system of teaching Anatomy that has hitherto obtained in the medical schools of the United Kingdom. If the selection of Examiners be wisely made, and the principles of the examinations be properly carried out, the faulty places in the anatomical and physiological teaching will be speedily detected, and a healthy stimulus will thereby be given to all schools, but especially to those which have lagged behind.

Annotations.

"Ne quid nimis."

CRIMINALITY AND INSANITY.

We publish this week an original communication from Dr. Maudsley in which he gives the details of a case which lately came under his notice. The case seems to us to be one of such unusual importance that we wish specially to direct the attention of our readers to it, and we wish we could insure that every member of the legal and medical professions should master the few simple facts which Dr. Maudsley sets forth. These facts are briefly as follows.

In September, 1874, Dr. Maudsley was consulted on behalf of a patient in whom he detected symptoms of general paralysis. At the urgent desire of the patient's wife, who could not easily be persuaded as to her husband's very serious condition, he was allowed to go to the seaside under her charge. Having obtained money under some pretext, he suddenly disappeared, and was next heard of at Doncaster, where he had been given in charge for stealing a watch. It appears that he had suddenly conceived the insane notion of going to Scotland, but, finding himself alone in a carriage with a sleeping fellow traveller, he was seized with an impulse to appropriate his watch. For his defence Dr. Maudsley furnished a certificate of insanity, and Dr. Crichton Browne gave evidence at the trial to the same effect. His ordinary medical attendant also gave similar evidence. "But it was all in vain. The surgeon of the gaol stated emphatically that he was sound in body and mind, and the evidence in his favour was received with open incredulity." In consequence, however, of the poor man's previous good character, he was sentenced only to two months' imprisonment with hard labour; and, by the representations of his friends, his discharge was obtained before the completion of the sentence. Owing, however, to divided family counsels, he was not, as he should have been, placed under legal restraint. He again escaped from the custody of his friends, and for the second time stole the watch of a passenger in a train. This time, however, there were found upon him a false beard and moustache and other evidence that he had had a design of committing robbery. On the 7th of December he was sent to the county gaol at Nottingham to await his trial, but, incontestable symptoms of insanity showing themselves, he was removed to the county asylum, where he died on August 31st of this year, nearly twelve months after Dr. Maudsley had diagnosed the fatal condition which caused, not only his death, but so much trouble to his friends and, one might say, to the public also. "Comment," says Dr. Maudsley, "upon this case is unnecessary." He states his conviction that "the time has come when it is the duty of medical corporations to exact some knowledge of mental diseases from those upon whom they confer their licences."

There can be no doubt that an affirmative answer is the only one that can be given to Dr. Maudsley's question. At the same time it does not appear to us to be the least surprising that a gaol surgeon should habitually look at a case from the standpoint of criminality, just as it not unfrequently has happened that a professed alienist has looked at a case too much from the standpoint of insanity. The lesson to be learnt, we think, is rather this—that the question of the insanity or sanity of a criminal is one that should be settled solely by medical assessors appointed by the Crown. A common jury is no doubt competent to determine whether or no a certain individual committed a certain act, but it is manifestly incompetent to come to any conclusion as to his state of mind, and it can hardly be blamed for looking doubtfully upon the evidence of persons who may be supposed (rightly or wrongly) to be in some way interested in its decision. It is, we have heard, not unlikely that in the new High Court of Judicature medical assessors may be appointed to advise the judges on medical points, and we should hail such an innovation as a great improvement on our present system. The mere fact that in this case the experts were all in the right, and the gaol surgeon in the wrong, appears to us to affect the question at issue in a very slight degree, and we can hardly blame the jury for coming to the decision it did, although certainly the symptoms of general paralysis appear to have been sufficiently well marked to render the gaol surgeon's difference of opinion very difficult to understand.

Another point of great importance is the second robbery, which clearly ought never to have occurred, and the authorities at the Home Office ought to explain why, when the prisoner was liberated on the ground of insanity, they did not insist on his being confined in an asylum until they should be satisfied, on the certificates of those who had testified to his insanity, that his malady had been cured. The patient had been proved to be a dangerous lunatic, and the authorities allowed him to go at large, and it seems to us to be merely a happy accident that the unfortunate man did not commit murder as well as robbery.

DR. HARDWICKE.

When Dr. Hardwicke became a candidate for the coronership of Central Middlesex, rendered vacant by the death of Dr. Lankester, there was a general determination on the part of the profession in the metropolis to support him as much as lay in their power, although, perhaps, there was an unexpressed regret that a more able man had not come forward from our ranks. We ourselves are thoroughly pledged to the principle of medical coronership, and we unhesitatingly and unstintedly espoused Dr. Hardwicke's candidature. When he was elected it might have been reasonably expected that the profession, without whose aid and co-operation he could not have secured the coveted post, would have received, we will not say gratitude, but certainly considerate treatment at his hands in his official capacity, and that he would protect the dignity of medical witnesses and likewise insist on the necessity of making post-mortem examinations in all cases in which there was any doubt existing as to the cause of death. Have these hopes been realised? Have medical men who have been professionally engaged before him at inquests reason to congratulate themselves upon finding in Dr. Hardwicke an exalted appreciation of the value of medical testimony? The reply is a most decided negative. It cannot be denied that his tenure of office has, so far, been marked by blunders and by a disposition to disparage the importance of medical men and to depreciate medical evidence. Soon after his appointment his singularly indiscreet management of the case of Sir Charles Lyell raised a public storm, which was only allayed by the assurance of Mr. Cross in the House of Commons that, if it should be found necessary, Government would "clip the wings" of coroners. We confess to a feeling of chagrin that this severe rebuke was evoked by the conduct of a medical occupant of the office. Within a more recent period there was a general condemnation of the character of Dr. Hardwicke's remarks on the occasion of an inquest when the word "atrocious" was used in regard to the proceeding of a medical brother. And, lastly, we have the inquest held last week at University College Hospital, in which gentlemen were threatened with pains and penalties for faults they had never committed. A specific accusation was made against a house-surgeon of the institution, Mr. Collyns, which he refuted in our issue of last week, with perfect ease. There was a lamentable want of judgment exhibited by Dr. Hardwicke at this inquest, and the Dean of the Hospital puts it mildly enough when he says that increased order and discretion are needed on the part of the coroner. We must, however, leave the consideration of Dr. Hardwicke's procedures to the superior judicial authority to which the office of coroner is subordinate.

THE DEBATE ON CROUP.

The paper and discussion on croup at the Medical and Chirurgical Society on Tuesday last cannot be said to have thrown much new light on the subject. The meeting was fortunate in obtaining the unexpected help of Sir William Jenner's presidency. But in spite of the historical research and declamatory energy of Dr. Semple, the graceful doubts of Dr. West, and the clearness and force of Sir William Jenner's argument, it was evident that, as was observed by Dr. West, the last word on the subject has not yet been spoken. Dr. Semple, interesting and important as was his collection of opinions from old writers, yet, in his facts and arguments, rather dwelt on the broad outlines of the question than touched the essential points in dispute. Our readers do not need to be informed that the identity of membranous croup and laryngeal diphtheria is, to him, a fact only needing clearer knowledge and more accurate generalisation for its universal recognition. This he insisted on, rather, however, by claiming the cases in dispute—those of sporadic membranous croup—as cases of diphtheria, than by controverting the objections on the ground of etiology and of association, which are the chief support of the view of the diversity of the two diseases. Dr. West's clear description of the contrasted clinical characters of the two diseases, "croup and diphtheria," was claimed by Dr. Semple as a conclusive argument for his own view of the question, on the ground that the simpler cases which formed the one term of the comparison, which were marked by sthenic, sudden characters, and rapid recovery, in which venesection had, in Dr. Cheyne's and Dr. West's hands, so speedily afforded relief, were really cases of non-membranous, simple laryngitis. Such, it must be confessed, was the impression conveyed by Dr. West's speech, but this was evidently not the meaning he intended to convey. We cannot but think that his remarks corroborated his disparagement of the value of historical evidence, whether in memory or in written record. Before the delicate symptomatic distinctions revealed by modern research were known, cases could not be distinguished with that accuracy which is essential for their value as evidence on a question of this nature. The concise summary which was given by Sir W. Jenner of the reasons which have led to his change of opinion, first expressed in these columns, left little to be desired as a presentation of the evidence in favour of the unity of "simple" membranous laryngitis and the diphtheritic form. Neither in origin, course, anatomy, nor ending, could a line be drawn between the two diseases which had not been more than once overstepped, from one side and from the other, within his own experience. Dr. Dickinson, in his few remarks, hardly did justice to his case on the other side. An experience which gives his opinion great weight leads him to place the causes of the two diseases in the foremost rank as evidence of their non-identity. Since simple membranous laryngitis may follow the operation of a non-specific influence, he could not accept the view that it is identical with a disease which manifests specific characters. He did not, however, grapple with the fact alluded to by Sir William Jenner, and to which we some time ago referred at length, that diphtheria, allowed by all to be such, may follow the operation of influences in which nothing specific can be traced. Abstract speculation regarding the nature of diseases must not be allowed more than a very slight influence in our generalisations regarding their relations. Upon the facts of their origin, course, and anatomy we must alone rely for our conclusions as to their nature. Such facts may well be collected by the Committee of the Medical and Chirurgical Society, which was asked for at the meeting, but we doubt whether the question will by that means be entirely put at rest.

INDIAN SANITARY REPORTS.

We had the hardihood recently to make an attempt at condensing within the compass of a short article some of the facts, figures, and conclusions contained in several of these publications, but we confess that the task proved too much for us. Of course, if the study of epidemiology is ever to advance, if we are ever to get an insight into the laws affecting the origin and development of epidemic diseases, we must be content to wait, watch, and record. We regard, for instance, the labours of Dr. Bryden as most valuable in this direction. Differing as we do from him in many of the interpretations which he has put upon the facts he has recorded, we have no doubt that his volumes supply a mine of information and abound in suggestions of a very valuable kind. But we wish we could see a little more careful and systematic study of the facts attending the origin and progress of some outbreaks of disease on a limited scale, made on the spot and recorded at the time, than we find in Indian reports in general.

Among the financial and other reforms about which we hear a good deal from time to time in our government of India, there is one direction in which, as it seems to us, the expenditure might be curtailed with advantage. We allude to printing. The great number, size, and variety of publications that appear under the title of Reports, sanitary, medical, and otherwise, are something bewildering; and many of them are uninteresting to a degree, being made up of pages and pages of figures. The hand becomes wearied with turning over the leaves, and no impression is left on the mind beyond that of a vague pattern of some huge sum in addition about which some one has been ruling a lot of lines in various directions. These pages are headed vital statistics, registers of births, deaths, diseases, vaccination, and what not; and if the reader turns to the letterpress he will find to his dismay, as the reward of his labours, that nowhere is the registration effective, and the conclusions consequently are utterly unreliable. And it can scarcely be otherwise, of course, where such vast populations and such extent of territory are concerned. Moreover, it is not very reassuring to an exact-minded man to find, for example, that "fever" is a term of such amplitude as to include all kinds of diseases in its embrace. If it be necessary for commissioners and others to draw up this vast number of tables, they should be sufficiently forbearing and unselfish to stow them away in official places, or at any rate to make a limited company of their circulating libraries. The cost of printing to the Indian Government must be enormous. We do not deny that some of these books, in blue, green, dirty yellow, white, and straw-coloured covers, are first-rate productions, valuable every way, and a few possess great scientific interest; but it is really time to inquire whether all this writing and printing be necessary. We are curious to know the unfortunate individuals condemned to read these records, and what condition of brain would be induced by the performance of such a feat. Mentally, the task of going through such an ocean of details would far exceed the physical labour of Captain Webb's in swimming the Channel.

THE MANCHESTER INFIRMARY.

For many weeks past the professional and non-professional public of Manchester have been in a state of agitation respecting their infirmary. It must be understood that the infirmary, which was built about one hundred and twenty years ago, is situated in a very large open space in the centre of the town, surrounded by many large and important places of business. For some years it has been felt that the resources of the infirmary were scarcely equal to the enormous demands that were made upon them, and that the building had of late become rife with erysipelas and pyæmia, and similar diseases; but by means of costly improvements and the establishment of a convalescent hospital, a fever hospital, and other attached institutions outside the town, matters have until lately been made to work fairly well. It has now, however, been discovered by some members of the administrative that the infirmary, notwithstanding all the improvements that have been made within it during the last twenty years, and in spite of the utmost care, cleanliness, and good management, is by no means as healthy as it had hitherto been supposed, but that according to some it is now little better than a "pest house." Others, on the other hand, indignantly repudiate these insinuations, and allege that the infirmary is one of the healthiest hospitals in the kingdom, and in support of this statement bring forward the evidence of the reports of the Board from year to year, and adduce the weighty testimony of the late Sir James Simpson, who reported very favourably of this institution. The real facts of the case seem to be that, although the infirmary is old and faulty in construction, it has been made clean and wholesome by the excellent management of the medical and lay staffs, and by this only; still it can scarcely be said to be a "pest house." Some correspondents of the *Manchester Guardian* seem to doubt whether any serious attempt would have been made to get rid of the old infirmary if it had not been thought that the valuable site on which it stands would, if put into the market, realise a considerable sum of money. It was at one time imagined that even six or seven hundred thousand pounds might be obtained for the plot of ground, and that with that sum one or two hospitals might be built on more scientific principles. There is a good deal to be said in favour of erecting a new infirmary, but the wisdom of the suggestion to take the building outside the town is not so evident. It is, perhaps, only natural that the authorities of Owens College should desire to have in the immediate vicinity a hospital in which their students would be able to prosecute their clinical and pathological studies, but it should not be forgotten that one of the most important uses of a hospital is to serve as a sanatorium for the sick poor, whose interests should also be considered. To remove the infirmary to a distance from the centre of the town would entail many inconveniences and great expense on some of the poorer applicants for admission, and the institution would sacrifice much of its utility. To obviate these evils, however, it has been proposed to establish a small hospital or receiving house near the present infirmary, into which urgent cases might be received. The proposal to erect several small hospitals in various parts of the town is scarcely deserving of serious consideration.

What objection is there to pulling down the present building, and erecting a new one on the same site, which is, for a hospital, perhaps one of the finest in any town in England?

THE WATER-SUPPLY AT THE ROYAL RESIDENCES.

THE Report of the Rivers' Pollution Commission just issued gives some important particulars on this subject. Some of the shallow well-water supplied to Osborne is of moderately good quality, but the remainder is unfit for dietetic purposes. Several trial wells sunk upon the estate have supplied palatable and wholesome water of moderate hardness. The water-supply at Windsor is derived from shallow wells sunk near the Thames, and, though hard, is of fairly good quality. Three varieties of water are used at Balmoral, two of which, severally from the Gelder Burn and the Rabate, are excellent; but the pump-water, though clear, colourless, and palatable, is contaminated by drainage, and the Commissioners recommend therefore that this well should be closed, and the Rabate water only used for drinking. A new well might, moreover, be sunk near the Dee, but not less than two hundred yards from the Castle. The water used at Abergeldie is clear, wholesome, and sparkling. The general water-supply is good, but peaty, being brought from Kentore Den, and would be much improved by filtration through sand, spongy iron, or animal charcoal. Sandringham is supplied with water from shallow wells sunk near the house, all of which are much polluted by animal matters, so as to make the water quite unfit for dietetic purposes, and it is, as the Commissioners report, "dangerous water." Abundance of excellent water is, however, obtainable within a short distance of Sandringham House.

LENGTH OF HOSPITAL RESIDENCE IN SCARLET FEVER CASES.

MUCH difference of opinion has been expressed as to the length of the period during which scarlet fever convalescents continue infectious. The authorities of hospitals for infectious diseases in which this disease is treated are, however, called upon to give a practical decision on this point, by sanctioning the discharge of the recovered cases to their homes. The Registrar-General, in his last Weekly Return, published some interesting statistics bearing upon the average duration of the 792 cases of scarlet fever treated in the two Metropolitan Asylum District Fever Hospitals at Homerton and Stockwell during the nine months ending September last. The average weekly number of beds occupied by scarlet fever patients during the nine months was 74 at Homerton and 49 at Stockwell; the cases disposed of during this period, by death or recovery, were 317 at Homerton and 373 at Stockwell. Although the number of beds occupied at Stockwell was 25 less than at Homerton, the numbers discharged, on recovery or by death, considerably exceeded those at Homerton. The average length of hospital residence of the recovered and fatal cases during the nine months, which was seven weeks and three days at Homerton, did not exceed four weeks and five days at Stockwell. Each of these averages understates the mean residence of the recovered cases, as they include the fatal cases, the duration of many of which does not exceed a few days. This does not, however, militate against the value of the figures for comparing the duration of the cases at Homerton and Stockwell. As we pointed out last week, the rate of mortality among the cases treated was almost identical in both hospitals, and it may therefore be presumed that there was but little difference in the nature of the cases admitted. The explanation of the fact that the duration of the cases of scarlet fever treated at Homerton exceeded by 58 per cent. the duration at Stockwell is not therefore apparent. The treatment of infectious diseases in hospitals recommends itself so strongly to sanitarians as the only means for controlling epidemics of this character, especially in large towns, that statistics bearing both upon the mortality in cases so treated, and upon the extent of isolation secured in these hospitals, are at the present time of great value. It would be desirable to ascertain by investigation whether the length of hospital residence which has been adopted at Stockwell is sufficient to secure safety in allowing the convalescents to return to their crowded homes. The hospital treatment of scarlet fever is at present more or less experimental, and the fullest information as to its results is most desirable.

DRINK AND DISEASE.

SOME curious calculations have been made of the proportional amount devoted by the working men of Birmingham to the support respectively of their public-houses and of their hospitals. The figures bear something like the ratio of 30 to 1. £3000 is contributed annually by them to the medical institutions of the town, and £900,000 is spent in drink. The numbers are, on their face, sufficiently startling, and may probably be taken as fairly representative of the state of affairs in most manufacturing districts. But they suggest that a further inquiry might elicit even more startling contrasts. What proportion does the contribution of the working men bear to the total expenses of the hospitals? The medical institutions are for them and for them only. What proportion of the burden do they bear? On the other hand, what proportion of the work of these medical institutions is occasioned by the drink on which they spend so much?

We confess that facts like these suggest a doubt of the value of the time-honoured custom of "support by voluntary contributions." We cannot but feel that the system, in such an instance, fails most completely, and that a radically new system of hospital support, a system of involuntary contribution, should be established and rigidly enforced. Such a measure would at least mete out as absolute a justice as the varying and inaccessible conditions of human life render possible. Let the drink consumed in every town be made to defray such proportion of its hospital expenses as it can be proved, with reasonable probability, that drink has caused. At present we afford to our working classes the freest facilities to drink—nay, more, we put in their way temptations to them irresistible. We remove every obstacle to as free a consumption of liquor as is consistent with the maintenance of equilibrium, and then, with a benevolent appropriateness, we provide hospitals in which the consequences of the drink can be recovered from, ameliorated, or assisted to a euthanasia.

The details of taxation lie beyond our province, but it seems at least a reasonable suggestion that the drink sold within a certain area should be so taxed as to defray the expenses of skilled treatment for those whom drink has prostrated and incapacitated for their work. The obstacle to drinking which such a tax must entail would have a beneficial influence, if slight, yet in the right direction.

THE CRUELTY OF FASHION.

A considerable demand for small birds, especially robins and wrens, has arisen within the last few months for the decoration of ladies' hats, this being the latest requirement of fashion. Not only are the birdcatchers of the Seven Dials and Whitechapel unusually busy, but we have the authority of the proprietor of a large West-end establishment for saying that, great as is the supply, it does not at all equal the demand. We need hardly say that this wholesale slaughter ought at once to be checked, for, as the supply falls short of the demand, we have no guarantee that other birds besides robins are not also destroyed, for no doubt a sparrow in the hands of a clever *artiste* could be made to do duty for a redbreast of brilliant plumage. The wanton slaughter of gulls, terns, &c., which formerly were used for hat decoration, has been stopped by a special Act of Parliament. Apart from the needless cruelty, the destruction of our small birds is a national injury. Whatever legal powers exist should, therefore, at once be put in force, to ensure their protection; and, if these are not sufficient, others must be obtained. We fear it is of little use appealing to the chief offenders—the leaders of fashion. Though the "rights of animals" are rigidly insisted on when the sacrifice of animal life is required for scientific experiment, we have found that these "rights" are seldom respected when the pleasure or convenience of society is concerned.

CONDITIONS OVERLOOKED.

At the last meeting of the Metropolitan Asylums Board, an important question was interposed between certain data crudely digested, and an inference, or, more correctly, an imputation, which it was sought to deduce from them. Mr. Proudfoot, on behalf of the Finance Committee, presented a report, purporting to show the causes of alleged "great differences between the cost of fever patients at Homerton and Stockwell Asylums." The difference was attributed to "medical extras," those at Homerton "averaging 6*d.* a day each patient, and at Stockwell 1½*d.*" The chairman of Finance was for sending the report to the committees of the two asylums in a shape which would have amounted to a censure, or at least provoked the Committee of Homerton to interfere with their medical officers. Dr. Cortis, happily, interposed with the proposal that the committees of the hospitals should be requested to give information on such matters as death-rate, and average duration of residence in the two institutions, both of those patients who recovered and of those who died—conditions obviously governing the expenditure, but which Mr. Proudfoot and his colleagues had most ludicrously overlooked. It is strange that points of vital moment like these should be almost systematically forgotten. We have heard of an inspector under the Poor-law Board looking only at the amount of stimulants ordered by the medical officer of a workhouse within a given period, and criticising his policy, without even taking the trouble to notice such particulars as the number of patients admitted, the nature of their maladies, their ages, or the temperature at the time. It is impossible that justice can be done either to patients or doctors, while important questions affecting treatment and its cost are disregarded. It is well that boards, committees, and their most fussy but least intelligent members, should be occasionally reminded of the facts their ignorance and prejudice cause them to treat with contempt.

FATAL OUTBREAK OF FEVER AT FORT CUMBERLAND, PORTSMOUTH.

A serious and fatal outbreak of typhoid fever has occurred among the recruits stationed at Fort Cumberland, at the entrance of Langston Harbour, Portsmouth. There have been altogether fifty-six cases. Of these sixteen have been well marked, the remainder being of a mild character. Unfortunately there have been four deaths. It is stated that the origin of the epidemic has been distinctly traced to sewage pollution. The whole sewage of Portsmouth, it appears, empties itself into Langston Harbour, and is discharged at the ebb. It has been ascertained, however, that instead of being always thus discharged, the sewage has repeatedly been pumped into the harbour at the flood tide, and, consequently, instead of being, as intended, carried out to sea, it is brought in shore and deposited on the mud-banks in close vicinity to the fort. It is also stated that other cases of typhoid have made their appearance at the artillery barracks at Hilsea, a point higher up the harbour. The whole subject is being inquired into by the medical department. The sick have been isolated and treated in a temporary hospital hut at Eastney, and the recruits, 130 in number, have been removed to Forton, on the Gosport side of the water.

CHOLERA IN SOUTH INDIA.

Referring to the prevalence of cholera in India, it has been suggested that the Prince of Wales, in his tour through the Madras Presidency, will cross the track which the disease has been making during the last four months, especially in the neighbourhood of Trichinopoly and Madura, and that a large concourse of Hindoos is generally the nucleus from which the disease propagates itself. It is improbable that cholera will become epidemic at this season, and still more improbable that the Prince will neglect the advice of those by whom he is accompanied. We may be quite certain that the latest intelligence will be available in regard to every district of India through which the Prince may be likely to pass, and that any alterations will be made in the programme of His Royal Highness's tour that may from time to time be deemed expedient.

THE MIDLAND MEDICAL SOCIETY.

The Inaugural Lecture of this Society was given at the Great Western Hotel, Birmingham, on November 13th (Dr. James Johnston, Physician to the Queen's Hospital, and President of the Society, in the chair), by Dr. B. W. Richardson, F.R.S. A large gathering of the medical men of the Midland Counties assembled to listen to his admirable address "On the Treatment of the Dying," and testified by earnest attention and frequent applause their appreciation of the ability and scientific knowledge displayed by the lecturer in dealing with this important subject. Dr. Richardson divided his lecture into four chief parts: first, a definition of the class of cases which are said to be *in extremis*; secondly, a correction of the old and general terms which have been used to designate the modes of death; thirdly, the actual modes of death as they may now be understood by the light of modern science; and, lastly, the specific modes of treatment in certain cases where death is imminent and, but for the resources of modern science, inevitable. Nitrite of amyl, transfusion, the administration of powerful doses of ammonia, and artificial respiration formed prominent subjects of illustration, and a new instrument for artificial respiration was exhibited. Mr. Oliver Pemberton, as ex-President of the Midland Medical Society, presented, on behalf of the members, to Mr. James Harmar, who has occupied the post of treasurer during the past ten years, a handsomely illuminated address, expressing the warmest thanks of the fellows and members for the excellent manner in which his duties have been performed, and their hearty appreciation of the devotion and energy he has exhibited in the onerous and too often thankless office of treasurer.

DUBLIN HOSPITAL SUNDAY FUND.

The second annual collection on behalf of this fund will be held on next Sunday, the 14th inst. The amount collected during last year was £3306, which, although a small sum as compared with the total income, £23,500, of the eight hospitals which participated in the benefits of the fund, was yet a substantial and valuable addition to the resources of those institutions. The demands on the fund this year will be greater than last, as some institutions which stood aloof will this year receive a share. The council state that they are glad to say that the Hospital Sunday collection has not injuriously affected the subscription-lists of those institutions which supported the movement last year, that many persons who declined to join last year have now offered their hearty co-operation, and that the number of churches and congregations supporting the movement has considerably increased.

BULLETS AND BRAINS.

The manager of a New Jersey paper has for the last seven months been known as "The Editor with a Bullet in his Brain." He was shot in his own office in March last, and recovered so completely that his assailant was released on bail, but relapsed, and died on the 24th of last month. A post-mortem examination was made, and "the bullet was found encrusted within the tentorium, beneath the posterior lobe of the right hemisphere." Three abscesses were found on the right hemisphere, there was marked congestion of the pia mater on the floor of the right ventricle, especially on the right side; the cerebellum was wholly uninjured. The opening (made by the bullet) was an inch to the right of the occipital protuberance, and half an inch above the groove of the right lateral sinus. We may expect further particulars of this interesting case.

MUSCULAR CONTRACTILITY IN A DECAPITATED CRIMINAL.

M. Onimus has had the opportunity of examining the muscles of a decapitated criminal shortly after death. He found that two hours after execution the right auricle beat spontaneously. The ventricle was quiescent, but the slightest stimulus applied to it caused it to contract. After the lapse of five hours, constant currents applied to the skin caused contraction of the subjacent muscles, though the same stimulus applied directly to the nerves no longer induced contraction.

SURGEONCY TO THE QUEEN IN IRELAND.

The lamented death of Mr. John Hamilton, of Dublin, necessitates the appointment of a successor as Surgeon to the Queen in Ireland. Among others who may reasonably hope for this honour is Mr. Rawdon Macnamara. Mr. Macnamara is an Irish surgeon of eminence, the representative of the Irish College of Surgeons in the General Medical Council; an ex-president of the College; an author of some repute in medicine; an M.D. *honoris causâ* of the University of Dublin; surgeon to the Meath Hospital, &c.

Some extremely interesting statistics have been published within the last few days in Paris respecting the extent and conditions of insanity in France. The physicians signing the report are of opinion that at least half the insane people in Paris had insane progenitors of more or less remote consanguinity. It is stated that there is a preponderance of single over married lunatics, but there are so many elements to be considered here that the deduction is not of much value. In Paris there is one lunatic in every 946 inhabitants. The French mind is found to be more liable to mental derangement between thirty and forty years of age than at any other period of life. The political throes through which the country passes, as may be expected, give a distinct character to mania. During the siege of Paris in 1870-1 many men went mad in endeavouring to devise means for annihilating the Germans, and the attempt to frame schemes of army reorganisation is found to have unhinged more than one. The report urges the desirability of making a thoroughly practical study of insanity a part of the education of medical men.

A serious outbreak of enteric fever is said to prevail at Stairfoot, a small village near Barnsley. About thirty cases have already been reported to the Barnsley rural authority. In one house a man was found lying ill on the floor in a state of nudity. In another, it was ascertained that a person slept during the day in a bed which at night was occupied by fever patients. After such painful disclosures the following resolution seems hopelessly insufficient to meet the emergency:—"Seeing, however, that Ardsley (in which township the infected village lies) is about to have a local board of health, it is not considered desirable that any action should be taken, but the sanitary officer is to do all in his power to prevent the fever extending." This is an easy way of evading obligations.

It has been pointed out that one good result of the Prince of Wales's visit to India will be in calling attention to the water-supply of Madras, which for a long time has been in a very unsatisfactory state. The Bishop of Madras has lately written strongly to the Government on the subject. The water which the citizens drink is said to be that which has percolated through graveyards where the victims of typhoid and cholera lie buried. In expectation of the Prince's sojourn at Government House stringent measures will be taken to ensure purity of water. It is significant that since 1860 two governors have died in this particular building, one from cholera and the other from enteric fever.

We understand that a new association for obtaining the repeal of the Contagious Diseases Acts has been formed. It will describe itself as the Social Purity Alliance, and, if report speaks truly, will appropriately have the distinguished aid of Mr. Theodore Tilton, of New York, in its propaganda. The opponents of the much-abused Acts are to be congratulated on the accession of such a coadjutor as Mr. Tilton. For the sake of the mistaken people who have taken up a senseless cry, it is to be hoped that the announcement is true. The utter ridicule which would attach to them in a crusade with such surroundings might do what reason, facts, and statistics have failed to do.

The town of Crediton, in Devonshire, is suffering severely from an epidemic of enteric fever. There have been reported up to this date 40 cases. The local sanitary authority is suspected to be apathetic in the matter; at all events it has been considered necessary to stir it up to a sense of the general peril by a deputation which clamoured for immediate suppressive measures.

A MOVEMENT is on foot for establishing a testimonial to Dr. Webster, J.P., in recognition of his valuable public services. The testimonial will take the somewhat unusual form of a trough and drinking fountain, to be erected in Dulwich, in which locality Dr. Webster practised for many years, in fact since 1815, although latterly his time has been completely taken up by his self-imposed duties in connexion with various public institutions and bodies. Judging by the articles we read in some of the lay papers, Dr. Webster must have a host of friends and admirers. We hope his useful career is far from closing.

IT seems rather hard that a policeman's differentiation of drunkenness from epilepsy should be considered absolute in the face of evidence given by other witnesses in favour of the latter hypothesis. A few days ago a gentleman was charged at the Westminster Police Court with the stereotyped crime of being "drunk and incapable." After the constable's deposition was taken, the gentleman's servant swore that his master was subject to epileptic fits. However, as the defendant elected to have the case settled at once, a penalty of five shillings was imposed, which terminated an affair that might have been made a *cause célèbre*.

AT the quarterly meeting of the Hartlepool Town Council last week, Dr. Moore remarked that during a residence in the town of over twenty years he never knew enteric fever to be so prevalent there as now; several cases, out of fifty which he was attending, were of unusual severity. He expressed the opinion that something was radically wrong with the drainage, and he thought it was the imperative duty of the Council to give the matter their most earnest attention.

IN London last week 1583 deaths were registered, including 1 from small-pox, 40 from measles, 129 from scarlet fever, 12 from diphtheria, 51 from whooping-cough, 23 from different forms of fever, and 24 from diarrhœa. Different forms of violence caused 47 deaths. The three Metropolitan Asylums District fever hospitals contained 264 scarlet fever patients last Saturday.

LADIES with a *penchant* for the practice of medicine, who have received more than one rebuff in the British Isles, appear to have met with more favour on the continent. Friends of the aspiring fair, have, it is stated, been so successful in enlisting sympathy on their behalf as to be able to announce the opening at Brussels of a School of Medicine for ladies on the 1st of December next.

FROM Japan we learn that a mysterious disease "which has hitherto baffled the investigations of European physicians" has broken out among the soldiers of the Imperial Guard. Thirty-seven men have already died. A special court of inquiry, composed of medical men, has been appointed to report on the disease.

WE have instituted inquiries into the facts of the case an account of which appeared in the daily papers on Thursday last, under the heading "Strange Hospital Treatment at King's College Hospital." As the inquest is adjourned, we refrain from making any comment at present.

LAST week the Vivisection Commissioners terminated their meetings for the taking of evidence, but will assemble again in the early part of December for the consideration of the report.

WE regret to learn of the very sudden death of Dr. Thos. Sarvis, a medical practitioner resident in Bethnal-green. Dr. Sarvis had been for many years in the Poor-law service.

OUR DOMESTIC WATER-SUPPLY.

IN directing the attention of our readers to the quality of the food that we eat, the water that we drink, and the air that we breathe, we not only supply information to those whose province it is to prescribe for and endeavour to cure the ills to which flesh is heir, but direct also into the proper channels the largely increasing class of those of our own and of allied professions whose care and concern it now is to prevent sickness and mortality among all classes of the teeming population of the kingdom. "The water that we drink and the water that we ought to drink" is the text of one of the most valuable Reports that has ever issued from an Imperial department. The sixth and final Report of the Rivers' Pollution Commission, which has just appeared, forms a most exhaustive document of more than five hundred pages, and includes, besides, maps that show the geological, hydrographical, and other aspects of the British Isles, and also the polluted river basins of the kingdom. The inquiries have extended over a period of more than six years, during which time the wells, springs, streams, and gathering grounds, from which a large number of corporations, local boards, and private companies derive their water, have been examined. The Commissioners have also analysed numerous specimens of spring, lake, and well waters supplied to communities for domestic purposes, and samples from the Cumberland, Westmoreland, and Lancashire lakes; and the springs issuing from important geological formations—as the chalk, greensand, carboniferous limestone, great oolites, and granite—have been likewise analysed, wherever the chemical examination of such samples promised to throw important light upon the effect on water of storage in large lakes, or of percolation through particular strata. These latter observations were specially necessary, because, as the Commissioners report, the numerous processes for cleansing water once contaminated with sewage or other similar noxious matters, as well as the so-called self-purifying power of streams contaminated with sewage, are altogether untrustworthy, and indeed practically inoperative. The works of eight private companies, who daily distribute upwards of one hundred million gallons of water to the inhabitants of London, have also been carefully inspected, an official work hitherto never before attempted in detail, and this inspection has been supplemented by the analysis of a large number of samples of rain-water, collected for the most part at a considerable distance from towns, with the object of ascertaining how far water which has undergone the natural process of distillation becomes contaminated before it reaches the surface of the earth as rain. As agricultural operations tend more or less to contaminate water, numerous samples have been submitted to analysis, collected from outfalls drawn by cultivated and pasture lands, both unmanured and dressed with various descriptions of manure. Sea-water has been also examined analytically to illustrate the ultimate disposal of the impurities which the various forms of land water carry with them to the ocean. So that, to quote *verbatim* from the report, "water has been thus followed through the complete cycle of its migrations; it has been caught as it descended from the clouds soon after its condensation from colourless and invisible vapour, collected as it flowed in streams after washing the surfaces upon which it fell, examined after it had penetrated to various depths through different geological strata, and, finally, it has been investigated after it had become part of the great mass of the ocean."

The report is very systematically and conveniently arranged under four heads—(1) the chemical examination of potable waters generally; (2) the classification and chemical composition of the potable waters of Great Britain; (3) discussions of special importance in connexion with the wholesomeness of certain kinds of water; (4) the condition of the water supplied to the metropolis, to a large number of cities, towns, villages, and rural districts throughout the country, and to the residences of Her Majesty and the Prince of Wales, which latter include Osborne, Windsor Castle and Frogmore, Balmoral Castle, Abergeldie, and Sandringham. There are also twelve appendices referring specially to rain and drainage waters, the quality of the metropolitan water for four years consecutively, the watershed and geological strata of the upper Thames, statistics of water-supply and mortality, tables illustrating the improvements of public health which result from proper works of drainage and water-supply, a special report on the cholera outbreak in the parish of St. James's, Westminster, in 1854 (with an illustrative map), and the analysis of potable waters by Dr. Frankland and Mr. H. L. Armstrong. Each and all of the parts into which the Report is divided will be noticed in further articles, as well as the appendices above-mentioned. The Commissioners have arrived at the following conclusions and recommendations: (1) That as to the chemical quality of water from different sources, rain-water collected at a distance from towns upon specially cleansed surfaces, and kept in clean receptacles, contains the smallest amount of total solid impurity; (2) that rain-water collected from the roofs of houses and stored in underground tanks is much more impure, and is often polluted to a dangerous extent; (3) that water collected from uncultivated land and allowed to subside in reservoirs, or filtered through sand, constitutes good water for domestic purposes; (4) that water collected from the surface or drains of cultivated land is always more or less polluted with organic matter, even after subsidence in lake or reservoirs, and hence is not good for domestic purposes; (5) that surface-water, draining wholly or partially from cultivated land, should be always efficiently filtered before being used; (6) that a large proportion of the river waters of Great Britain are dangerous, or are rapidly becoming so, from drainage from land, towns, and manufactories; (7) that shallow well-water is usually saturated with leakage or soakage from privies, drains, or cesspools, but it is generally, in spite of these disgusting and dangerous matters, bright, sparkling, and palatable; (8) that of the different varieties of potable water the best for dietetic purposes are spring and deep well-waters. It is concluded that polluted water cannot by any existing processes be rendered wholesome, that the propagation of epidemic diseases by polluted water is now so evident that it may be classed as a fact, that the mortality is not influenced by the hardness of potable water, that there is no trustworthy evidence as to the definite improvement of water by filtration, that if mains are properly laid no deterioration of water in its transmission need ensue, and that the constant-supply system is more sanitary and more economical in its results than any other.

In summarising the conclusions as to the metropolitan supply, it is reported that the Thames above the intake of all the companies receives the sewage of a large number of towns and other inhabited places, the washings of a large area of highly cultivated land, and the filthy discharges from many industrial processes and manufactures. The river is used also for bathing, for the washing of sheep, cattle, and dirty linen. For these and other reasons it is recommended that the Thames should be entirely abandoned as a source of water for domestic use. The same recommendations are also recorded (and on account of similar causes) as to the Lea. It is recommended that the public pumps should be all closed except that near the south-east entrance to Kensington Gardens and one at Maritime Houses, in Mile-end Old Town, but that the use of the water supplied by the Kent Company, from deep wells in the chalk at Deptford, should be continued and extended. The proposed supply of water to the metropolis from North Wales and from the Cumberland lakes is considered costly and unnecessary, but an abundant supply of spring and deep well-water can be procured in the basin of the Thames, at a moderate distance from London, so that the metropolis and its suburbs can, with efficient management, be supplied on the constant system, the water being, before delivery, softened with lime. To inaugurate the introduction of such a system it would be necessary either to throw open the metropolitan water-supply to the competition of new private companies, or to transfer the control of that supply to a responsible body invested with the necessary powers for the purchase of the existing works and the acquisition of so much spring and deep well water as may be necessary. We have continuously and persistently advocated the latter scheme as the one thing needful in this gigantic and superlatively important matter, and are, therefore, very glad to find that the Commissioners give it a very strong comparative preference. The summary of conclusions and recommendations as to the rural districts must be postponed; but we may fitly end by complimenting very highly the Commissioners, and by urging their recommendations (as regards London) upon the attention of the Corporation and the Metropolitan Board of Works. No skilled Report was ever published at so happy a time, if these august bodies only know how to make it serve their own laudably ambitious purposes. We may remind them that water is of more importance than gas.

Correspondence.

"Audi alteram partem."

PROFESSOR MACLEAN, C.B., ON THE TRUE COMPOSITION AND THERAPEUTIC VALUE OF WARBURG'S TINCTURE.

To the Editor of THE LANCET.

SIR,—Dr. Carl Warburg, late of Vienna, now of London, acting on the advice of friends well acquainted with the antipyretic properties of his tincture, has communicated to me for publication the formula for its preparation, which I accordingly give below. Thirty ounces of the tincture, according to the formula, were prepared in my presence in the laboratory here.

It is well known that up to this time this has been a secret remedy. It is no business of mine to defend its author from the charge of vending a secret medicine, which he shares in common with some other members of the profession not unknown. The simple truth is that Dr. Warburg knew he had hit on a remedy of great therapeutic value, and, under the pressure of the *res angusta domi*, hoped by its sale to maintain his family.

The feeling in the profession against secret remedies was so strong that his expectations, after many years of trial and many disappointments, have not been fulfilled, and, as I have said, he has at last, wisely as I think, resolved to make his secret known.

Before passing from this part of my subject, I may quote, as pretty nearly expressing my own opinion on the subject of secret remedies, the following passage by the late Dr. James Johnson:—"No one will accuse us of favouring secret nostrums, but if the inventors of remedies will not publish their compositions, this is no reason why we should not test their efficacy when they come from practical and scientific men. Would any man in his senses, or who has any regard for the welfare of his patients, refuse to administer James's Powder, Battley's Sedative Liquor, or Ruspini's Styptic, because the inventors refuse to make known the composition of these remedies? Dr. Warburg has supplied gratuitously immense quantities of his febrifuge to the profession, and continues to do so, in order that his statements respecting its properties may be fairly put to the test. This is, perhaps, as much as could be expected." Dr. Johnson concluded his notice of the tincture by inviting "the attention of our brethren in this country to this remarkable preparation."

I first became acquainted with the remarkable properties of Warburg's tincture in the following manner. Many years ago, when attached to the Residency of Hyderabad in the Deccan, word was brought to the Resident, the late General James Stewart Fraser, that his son-in-law, the late Dr. Thomas Lancaster Bell, then employed as statistical surveyor of the Deccan, had been brought into the station of Warrunghal, about eighty miles from Hyderabad, in an almost comatose state from remittent fever, caught in a neighbouring jungle, where he was carrying on some scientific investigations, and that but slender hopes were entertained of his recovery. I hastened to his assistance. On arriving at the station I approached the house where the patient was from the rear, and seeing many sheets and other articles of bedding hanging out to dry, I naturally interpreted this into a mournful signal that all was over, that in fact I had arrived in time to bury but not to save my friend. Entering the house I was joyfully surprised to see Dr. Bell seated in an arm-chair in a state of complete convalescence. I then learned that he had been brought by his servants to the station just as an exacerbation of his fever had set in, being the third or fourth of his attack. Dr. Bell had taken quinine freely when first attacked, but was quickly reduced to such a condition of mental confusion as to be incapable of directing the treatment of his case. When seen by the medical officer of the station he was in a most alarming condition, and it was too evident that another exacerbation would prove fatal. It so happened that an officer belonging to the Mysore Commission was visiting a friend in the cantonment who was not only well acquainted with the efficacy of the tincture in malarial fevers, but had a supply of it with him. In the desperate circumstances of the case the station surgeon administered the remedy; it was followed by a profuse but not exhausting action of the skin (hence the drying process which had alarmed me), the fever did not return, and the patient made a rapid recovery.

After such an experience as this, I did not fail to use it in similar cases, as opportunities offered, and by its means rescued many who were in as great peril as in the case related above. My experience in the treatment of malarial fevers by Warburg's tincture has not been confined to India. My friend and colleague, Surgeon-Major Madden, will remember the case of a young officer of the Royal Engineers, who had the misfortune to be quartered in a building much below the level of the surrounding ground on which stand Brompton Barracks, Chatham, where he was nightly exposed to the poisonous emanations conveyed by the wind from the unwholesome marshes of the Medway. He contracted a sharp remittent fever, which resisted quinine given in free doses. The case became alarming, and I was asked to see him. I at once administered Warburg's tincture in the manner to be presently described, and this young man never had another exacerbation.

A supply of this tincture was sent to the Gold Coast for use in the late expedition, but from all I can learn it was not much used by the medical officers of the force. After the war the *Victor Emanuel*, that model hospital-ship, now unfortunately dismantled, was anchored off Netley. From the medical stores of this ship I obtained all the "Warburg" remaining, and used every bottle of it in the treatment of the formidable fevers disembarked from the Gold Coast at Netley, in every case with success when not complicated with hepatic abscess.

I have only to add, in concluding this account of my personal experience of the remedy, that in the article on Malarial Fevers contributed by me to Dr. Russell Reynolds's System of Medicine, I spoke highly of this febrifuge, for which I was taken to task by a writer in the *Indian Annals of Medicine;* and for the last fifteen years, in my lectures on Tropical Medicine here, I have made known its value to the gentlemen belonging to the public services going through the course of special instruction in the Army Medical School.

To the best of my knowledge Warburg's tincture was first introduced into Southern India, for use on a large scale, by the late Lieut.-General Sir Mark Cubbon, K.C.B., Commissioner of the Mysore Province, who will long be remembered in India as one of the most successful administrators of his time, and of a service prolific in splendid examples of a governing race. Having himself used the remedy with success, he placed at first 500 and subsequently 1000 bottles of it at the disposal of the late Dr. C. J. Smith, being well known as surgeon to the Mysore Commission. Ere long its reputation was established at Mysore among the officers of the Commission (much exposed to malaria in the discharge of their duties), and I believe I am right when I say that none of them ever ventured into a malarious locality without being armed with "a little bottle of Warburg."

I have not space at my command to say more of its use in Southern India, where it was always better known and more used than either in the Bengal or Bombay Presidencies. Many great engineering works in Southern India, carried on in "deadly jungles," were brought to a successful issue mainly by the protection afforded to the workmen by this medicine. Some remarkable evidence on this point was placed before the Royal Commission which inquired into the health of the Army of India by my friend Major-General Cotton, R E.

I have only to add that many very eminent members of the profession in this country, among whom I may instance Sir Andrew Halliday, the late Sir James Gibson (Director-General of the Medical Department of the Army), the late Dr. Babington, Mr. Skey, and many others, were led to use this febrifuge, and have left on record strong evidence of its value as a therapeutic agent. The same is true of many distinguished physicians and teachers on the Continent.

It will be seen that quinine is the most important ingredient in the formula, each ounce bottle containing nine grains and a half of the alkaloid. Its presence has been detected by every chemist who has attempted its analysis, and never doubted by any medical man of experience who has used the tincture. Many will say, "'After all,' this vaunted remedy is only quinine concealed in a farrago of inert substances for purposes of 'mystification.'" To this objection my answer is, I have treated remittent fevers of every degree of severity contracted in the jungles of the Deccan and Mysore, at the base of mountain ranges in India, on the Coromandel Coast, in the pestilential highlands of the northern division of the Madras Presidency, in the malarial rivers of China, and in men brought to this hospital from the swamps of the Gold Coast, and I affirm that I have never seen quinine, when given alone, act in the manner characteristic of this tincture; and although I yield to no one in my high opinion of the inestimable value of quinine, I have never seen a single dose of it given alone, to the extent of nine grains and a half, suffice to arrest an exacerbation of remittent fever, much less prevent its recurrence, while nothing is more common than to see the same quantity of the alkaloid in Warburg's tincture bring about both results.

I am prepared also to hear that I am giving undue importance to this remedy. But I cannot forget that, taking one year with another, fevers destroy twice as many people as small-pox, cholera, and all other epidemic causes put together.* Therefore it is that a therapeutic agent vouched, on testimony which I submit is trustworthy, to be more efficacious in a certain class of diseases than any other known remedy, is a matter of supreme importance to our native fellow-subjects, and to the well-being of the sixty and odd thousand British soldiers who hold this great possession for the Crown and people of India.

In conclusion, I venture to express a hope that, the reproach of secrecy being now removed, a more extensive and fair trial may be given to this remedy, particularly in the public services, than it has yet had, and that, if it be found to be such as I have described in this notice, its author will not be left to find his only reward in the consciousness of having deserved well of his kind.

The tincture is administered in the following manner:— One half ounce (half of a bottle) is given alone without dilution, after the bowels have been evacuated by any convenient purgative, all drink being withheld; in three hours the other half of the bottle is administered in the same way. Soon afterwards, particularly in hot climates, profuse, but seldom exhausting, perspiration is produced; this has a strong aromatic odour, which I have often detected about the patient and his room on the following day. With this there is a rapid decline of temperature, immediate abatement of frontal headache—in a word, complete defervescence, and it seldom happens that a second bottle is required. If so, the dose must be repeated as above. In very adynamic cases, if the sweating threatens to prove exhausting, nourishment in the shape of beef-tea, with the addition of Liebig's extract and some wine or brandy of good quality, may be required.

---

* Dr. Cornish, Sanitary Commissioner, Madras.

In the terrible remittent fevers described by Livingstone and his followers, the form of purgative prescribed by the great traveller, and known to his people as "Livingstone's Rousers," may be premised. By no authors is the necessity for careful nutrition and due stimulation so much insisted on as by the companions of this immortal explorer, notably by the Rev. Mr. Waller, who, I believe, is a physician as well as a missionary.

DR. WARBURG'S TINCTURE.

℞ Aloes (socotr.) libram,
Rad. Rhei (East India),
Sem. Angelicæ,
*Confect. Damocratis, ana uncias quatuor;
Rad. Helenis (s. Enulæ),
Croci sativi,
Sem. Fœniculi,
†Cret. præparat., ana unc. duas;
Rad. Gentianæ,
Rad. Zedoariæ,
Pip. Cubeb.,
Myrrh. elect.,
Camphoræ,
‡Boleti laricis, ana unciam.

The above ingredients to be digested with 500 ounces of proof spirit in a water-bath for 12 hours; then expressed and ten ounces of disulphate of quinine added; the mixture to be replaced in the water-bath till all quinine is dissolved. The liquor, when cool, is to be filtered, and is then fit for use.

Your obedient servant,
Netley, Nov. 1875. W. C. MACLEAN.

THE MEDICAL SOCIETY OF LONDON.

To the Editor of THE LANCET.

SIR,—At a meeting of the Council of this Society held yesterday, attention was directed to an article on the Metropolitan Medical Societies, which appeared in THE LANCET, October 9th, in which, after awarding its due meed of praise to the work done by this Society, you remark, "It is much to be regretted that no Transactions of this Society have yet been published." I am requested by the Council to state that a volume of Proceedings was issued to the Fellows in October, 1874, and that a second volume edited by the Secretaries is now in the press and will shortly be in circulation.

I have the honour to remain, Sir, your obedient servant,
C. THEODORE WILLIAMS, M.D.,
Nov. 6th, 1875. Honorary Secretary.

SMALL-POX IN SAXONY.

To the Editor of THE LANCET.

SIR,—In No. 17 of Volume II. of your valuable paper of this year, it is said (p. 610), in the article Small-pox: "No official accounts of Saxony are forthcoming." I am glad to give you the desired account. As to the year 1871, the official information on the total small-pox deaths is not quite certain; but I believe that there may have been at least 9000; in the year 1872 there were 5863; in 1873, 1772. In these last two years 30 per cent. of the deaths were in children under the age of one year.

The number of the population of Saxony was on the 1st December, 1871, 2,556,244. The small-pox death-rate per 1000 of population was therefore: 1871, 3·5; 1872, 2·2; 1873, 0·7. I am, Sir, yours faithfully,
R. GUENTHER, M.D.,
Medical Officer of the Privy Council.
Dresden, 5th November, 1875.

GLASGOW.

(From our own Correspondent.)

THE various medical classes in connexion with Glasgow are now in full working order. The opening address to the students at the University was delivered by Dr. George Buchanan, the Professor of Clinical Surgery, and was fairly received by a noisily appreciative audience of the young alumni. On the following day the Dean of the Medical Faculty, Dr. Alexander Lindsay, gave the inaugural discourse at the Andersonian University. The well-known ability and experience of the lecturer secured him a large audience. Instead of choosing any stereotype subject, Dr. Lindsay spoke of some of those conditions that rule in the world of matter, selecting more particularly the laws of diversity, unity, and economy, and illustrated and dwelt on the divisions under these heads. His address was well received, and was delivered without the aid of note or manuscript. In addition to the two schools mentioned, we have the nucleus of an extramural school, and lectures on surgery and medical jurisprudence are being delivered. The University authorities have resolved to recognise these lectures as qualifying for graduation. This is as it should be, but the same privilege should be extended to the lectures at the Andersonian. The majority of the medical profession in the University were at one time lecturers at the Andersonian before their advancement to their present chairs, and, when acting as such, vigorously and justly clamoured against a monopoly of teaching. On their promotion they appear, however, to forget their former views, and abandon a liberal policy. The ostensible cause given for the non-recognition of the teachers is the fact that, according to the conditions of the founder of the school, those elected to the various chairs should be called professors of the subjects they expounded. They thus, it is said, become rivals, not merely in teaching, but in the actual possession of a title. I venture to think that such reasoning is unworthy of any university, and trust a more generous one may be adopted. The recognition of extramural lectures has enhanced greatly the reputation of Edinburgh as a medical school, and the same mode of procedure to all here it is presumable would promote in every way the true interests of medical science.

Favoured by excellent weather, Dr. Russell has for the last three weeks been able to report a wonderfully healthy condition of affairs, the mortality tables indicating an average of only 21 per 1000, against 31 of the same month of last year.

There has been since the commencement of August last a somewhat bitter feeling between the directors of the Royal Infirmary and the Police Board, which culminated in a meeting between the different representatives on 3rd Nov. Full details are given in the daily papers, and will doubtless give rise to much discussion. Briefly stated, the matter under dispute was this. In the suburban burghs enteric fever had been prevalent for some time, and Dr. Russell was anxious to obtain information as to the locality of such cases which had been removed to the Royal Infirmary, and with the ostensible object also of having such cases sent to the Fever Hospital at Belvidere, which is under the control of the municipal authorities of Glasgow. The infirmary directors declined to accede to this request, and a somewhat personal and hasty correspondence in the daily papers took place between the superintendent of the infirmary and Dr. Russell. The conclusion come to at the meeting will be seen from the following summary from one of our daily papers:—

"A conference took place yesterday between the managers of Glasgow Infirmary and the Health Committee of the Police Board, with the view of arrangements being made for information being given to the Sanitary Department of all fever cases sent to the infirmary. Mr. William MacEwan, on behalf of the managers, read a statement in reply to the minute adopted by a recent meeting of the Police Board, in which he denied that the managers of the infirmary had in any way aided the authorities in neighbouring burghs to evade their responsibility. He also explained that, in virtue of payments made some time ago, and of annual contributions, certain parties had a right to send their patients to the infirmary. He also emphatically denied the allegation that sewage was sent from the infirmary into the sewers to the detriment of the public health. The Heath Committee, on their part, disclaimed all intention of injuring the infirmary, but argued that it was necessary, to enable them to protect the health of the city, they should be made aware of all cases of epidemic disease within their bounds, and of all cases imported from neighbouring districts. The directors consented to give returns of all fever cases sent into the infirmary from the city, but declined to be made middlemen between the Health Committee and the suburban burghs."

---

* This confection, which consists of an immense variety of aromatic substances, was once officinal, and is to be found in the Ph. Lond., 1746.

† Dr. Warburg informs me that this ingredient was added to correct the otherwise extremely acrid taste of the tincture. Many other substances were tried, but none answered so well as prepared chalk.

‡ This is the Polyporus laricis (P. officinalis, Boletus purgans, or Larch agaric), "formerly," says Pereira, "used as a drastic purgative, and still kept by the herbalist."

It is understood that the infirmary directors at their last quarterly meeting resolved to increase the salaries of each of the medical officers by an addition of £50 for the ensuing year.

Glasgow, November 8th, 1875.

IRELAND.

(*From our own Correspondent.*)

Medical and other scientific meetings and lectures have once again become the order of the day. Freshmen from the country are visible in the Irish metropolis intent on study or the appearance of it, or on the pleasures associated with the return of citizens and sojourners to Dublin. Opening addresses have for several days been the rage in the medical schools and hospitals, many of these orations presenting features of interest to the general as well as to the medical hearers. One delivered at the Meath Hospital, by Dr. Stokes's comparatively young successor, has been accorded a very considerable meed of praise. Dr. John Wm. Moore promises to fill worthily the place vacated by the celebrated Stokes. On Wednesday next, at the College of Physicians, it is proposed to hold the opening meeting of the Medical Society of that body. To-night the veteran Dr. Stokes opens the session of the Royal Irish Academy.

Death has, as your columns have already announced, removed another leading member of the medical profession. John Hamilton has passed from amongst us. His illness and death have not been quite correctly described, as I am informed; but a statement will, I am told, shortly be given as to the exact nature of the disease which proved fatal to him, and, awaiting this, I abstain from further comment. Very many patients lose a valued professional adviser by Mr. Hamilton's decease.

Dublin, Nov. 8th, 1875.

Obituary.

GEORGE ROSS, M.D.

We have to record the death of Dr. George Ross, which took place at his residence, 11, Hart-street, Bloomsbury, after a short illness, in the fifty-eighth year of his age. The deceased was the eldest son of George Ross, Esq., of Stoke, and grandson of George Ross, of Dalkeith, a lineal descendant of the ancient branch of the family of Ross. He evidenced at an early age an active and inquiring mind, and as a boy commenced to give literary form to his ideas. The taste grew with his years, and in manhood shaped the course of his life. He entered the medical profession as pupil to Mr. Phillips, of Albion-street, Hyde-park, and received his professional education at St. George's Hospital. Literature was his dream from boyhood. His first published efforts appeared in the pages of the *Old Monthly*, to which he became a frequent contributor. Some of his published poems are of a very high order. He resolved, however, at last to give himself wholly to his legitimate profession. In 1852 the late Mr. Yearsley proposed to Dr. Ross to start in conformity with him a new journal, and soon after the *Medical Circular* appeared, Dr. Ross undertaking the duties of editor.

In 1854 Dr. Ross was elected by the constituents of the ward of Farringdon Without their representative in the Corporation of the City of London. In 1869, when the office of medical officer of health for St. Giles's and Bloomsbury was vacant, almost at the last moment Dr. Ross was urged to come forward. He did so, and was appointed. This office he held until his death; and the regard in which his services were held is best testified by the resolution which was passed at the meeting of the vestry following his decease. Dr. Ross was a graduate of the University of St. Andrews, M.D, L.R.C.P. Edin., M.R.C.S. Eng., &c. He was a member of the Charity Organisation Society, and of the Commission of Sewers; Vice-President of the Society of Medical Officers of Health; and a member of the Civil Engineering Committee and the Sanitary Sub-committee of the International Exhibition, 1874.

WILLIAM RICHARDSON, M.D.

We have to record the death at Kilburn, on the 18th of September, of Dr. William Richardson, author of "Remarks upon Diabetes, especially in reference to Treatment." He was born at Perth, July 26th, 1811, and was descended from an old Scotch family. At the age of 18 he graduated M.A. at the University of Aberdeen. Shortly afterwards he came to London, and was admitted a member of the College of Surgeons. In 1850 he graduated M.D. at St. Andrews with great distinction, after which he became M.R.C.P., receiving the highest encomiums from his examiners. In 1853 he went to Tunbridge Wells, and without any introduction speedily became the leading physician of the place. In 1860 he was attacked by diabetes in its worst form; by his own treatment and the use of means pointed out in his treatise he was able to enjoy life and continue his practice until 1868, from which period he lived comparatively in retirement. Having lived the life of a sincere Christian, his end was illumined by a sure hope of better things to come. He leaves a large circle of relatives and friends who deeply mourn his loss.

GEORGE ALLARTON, M.R.C.S. Eng., L.S.A.

Mr. George Allarton died at his residence, South-street, Southmolton (where he had been medical practitioner for over 17 years), on Friday, October 29th, aged 62 years, and his remains were interred in the cemetery there on November 4th. He was in medical practice in West Bromwich for more than twenty years, and was deputy coroner for South Staffordshire. He was also the author of the following works—viz., "Lithotomy Simplified," "An Interesting and Unique Case of Cæsarean Section," and a "Treatise on Median Lithotomy." Mr. Allarton was a man of great learning and ability.

THE ROYAL COLLEGE OF SURGEONS.

At an ordinary meeting of the Council of the Royal College of Surgeons held on Thursday last, Mr. Marshall introduced an elaborate scheme proposing that all intending candidates for the diploma of Member or Fellow of the College should be compelled to pass a compulsory and authoritative elementary examination at the end of the first winter, or immediately after the commencement of the succeeding summer session. Mr. Marshall has been led to make this suggestion by the large number of rejections at the Primary Examinations at the College and the unsatisfactory kind of knowledge possessed by many candidates who do pass. If there were a compulsory examination in Anatomy and Physiology at the end of the first year, Mr. Marshall thinks that many students who now squander away their time would be induced to apply themselves to work, and by that means be diverted from an idle and profitless course of life, and made useful members of the profession. Although the scheme was on the whole kindly received by the Council, many objections were suggested, and the question was finally referred to a committee for consideration.

Medical News.

Royal College of Surgeons of England. — The following gentlemen passed the Primary Examination in Anatomy and Physiology at a meeting of the Court of Examiners on Tuesday last:—

C. Knox and T. H. Lewis, Liverpool; J. R. Clark, G. H. Burnham, C. M'Larty, T. Millman, and M. D. Stark, Toronto; H. B. P. Barry, London Hospital; A. T. Wilkinson, Manchester; John Christian, W. K. Davies, J. H. Marsh, S. T. Proctor, and E. P. Thurstan, St. Thomas's Hospital; W. A. Dingle, W. F. Mayne, and W. H. T. Winter, St. Bartholomew's Hospital; C. S. Rundle and C. S. Kilner, Edinburgh; H. W. Thomas, Birmingham; E. C. Beale, Cambridge; G. A. Walker, Edinburgh and Aberdeen; W. D. Jefferson, King's College; W. F. Hopwood and H. A. Layton, University College; J. C. Saunders, Cambridge and St. Bartholomew's Hospital; T. Jones, C. G. W. Lowdell, and J. H. Poland, Guy's Hospital.

Of the 41 candidates examined, 12 failed to satisfy the Court of Examiners, and were referred for three months' further anatomical and physiological study.

University of London.—The following is a list of the candidates who have passed the recent 2nd M.B. examination:—

FIRST DIVISION.

Batterbury, George Henry, King's College.
Batterbury, Richard Legg, King's College.
Garlick, George, University College.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Nov. 4th:—

Betty, Samuel George, Park-street, Regent's-park.
Heard, Charles Goodridge, Truro, Cornwall.
Jackson, Edwin, Whalley Range, Manchester.
Kay, Alfred, Commercial-road East.
Knight, John Tomlinson, Sandiacre, Derbyshire.
Marsh, Edwin Addison, Arthur-road, Brixton.
Parkinson, Sidney George, Infirmary, Northampton.

Dr. Atthill, vice-president of the College of Physicians, was last week elected master of the Rotundo Lying-in Hospital, Dublin.

Benjamin Barkus, M.D., and Robert J. Banning, M.D., have qualified as Justices of the Peace for the borough of Gateshead-on-Tyne.

Statistical Society.—The first ordinary meeting of the present session will be held on Tuesday, the 16th inst., at the Society's Rooms, Somerset House-terrace, Strand, when the President, James Heywood, Esq., M.A., F.R.S., will deliver his inaugural address, and present the Howard Medal to the successful candidate, this being the first award. Mr. E. G. Ravenstein, F.R.G.S., will give "Statistics collected at the Geographical Congress in Paris"; and Dr. W. A. Guy, F.R.S., will read a paper on "John Howard's true place in History." The chair will be taken at 7.45 P.M.

Presentations.—Mr. James Middleton has been presented with a large silver tray bearing the following inscription:—"To James Middleton, Esq., M.R.C.P., M.R.C.S., from a few friends on his retiring from the office of physician to the City Dispensary, in token of their high esteem, and as an acknowledgment of his unwearied services during a period of thirty years." The presentation was made by the Lord Mayor at a meeting of the governors of the dispensary at the Mansion House on Wednesday, the 3rd inst.—Mr. W. J. Fleetwood, who has been connected with the Chester General Infirmary for four years, at first as visiting, and afterwards as house surgeon, was presented, on his resignation on October 14th, with a handsome case of operating instruments by the visiting surgeon, matron, dispenser, nurses, and servants of the institution.

Grange-over-Sands.—Scarlet fever has been again prevalent in this place of resort, and in all the surrounding villages for many weeks past. It will hardly be credited that although the village boasts of a local board, which has been in existence for above twelve months, not a single effort has been made to improve the drainage, which for years has been notoriously defective.

Medical Appointments.

Bond, J., L.R.C.P.Ed., L.M., L.R.C.S.I., has been appointed Assistant Medical Officer to the Haydock Lodge Lunatic Asylum, Newton-le-Willows, vice Johnstone, resigned.
